Comparative development of two wheat varieties under varying moisture supply, J. W. HOPKINS (*Canad. Jour. Res.*, 17 (1939), No. 4, Sect. C, pp. 87-96, figs. 4).—When *Lutescens* and a cross of *Roward* × *Caesum* wheat were

grown in the greenhouse at four levels of soil moisture, significant effects of moisture supply on number, height, and weight of shoots, number of fertile heads, and weight, size, and nitrogen content of grain per plant and per shoot, differing in some cases in the two varieties, were shown. Relation between production of straw and fruiting parts per tiller seemed to be a varietal characteristic.

The response of quack grass to variations in height of cutting and rates of application of nitrogen, A. A. JOHNSON and S. T. DEXTER. (Mich. Expt. Sta.). (*Four. Amer. Soc. Agron.*, 31 (1939), No. 1, pp. 67-76, figs. 3).—Quack-grass (K. S. R., 77, p. 332), grown in sand cultures in the greenhouse, with and without nitrogen, was cut weekly during 24 weeks to 1-, 3-, 6-, and 8-in. heights. At the end of the period the plus-nitrogen, close-cut cultures were dead, while the minus-nitrogen, close-cut grass was still alive and retained one-third of the original rhizome weight. Cutting cultures to 1 in. once a week was very injurious to plus-nitrogen plants but caused only slight injury to minus-nitrogen plants. Plus-nitrogen cultures cut to 3 in. lost in rhizome, root, and top weight, while in minus-nitrogen cultures rhizome weight increased and there was some loss of root weight and a large loss in top weight. Minus-nitrogen plants stored organic reserves in subterranean parts at a more severe cutting level than did plus-nitrogen plants. Minus-nitrogen cultures completely defoliated weekly produced only slightly less recovery growth than did plus-nitrogen cultures cut the same and yielded about twice as much as the next highest minus-nitrogen cutting treatment. These studies, if indicative of growth habits under field conditions, suggest that the fertilization of quackgrass should give an increase in top growth which could be used for hay or pasture, and that subsequent control measures on quackgrass thus fertilized should prove less difficult.

The relation of nutrients to toxicity of arsenic, borax, and chlorate in soils, A. S. CRAFTS. (U. S. D. A. and Calif. Expt. Sta.). (*Jour. Agr. Res.* [U. S.], 58 (1939), No. 9, pp. 657-671, figs. 12).—Current research on response to herbicides acting through the soil has shown that arsenic and boron toxicity are correlated with texture, while chlorate toxicity depends upon fertility. In experiments reported in this paper increasing the nutrient level lowered chlorate toxicity but did not affect arsenic and boron toxicity. In single-salt soil-culture series with a range of chlorate concentrations, cultures with added nitrate invariably showed decreased chlorate toxicity, and in fertile soil cultures chlorides and sulfates also reduced the toxicity. Cations in the culture medium did not affect chlorate toxicity except where ammonium ions were nitrified rapidly. The results obtained with soil cultures were confirmed with water-culture experiments. Absorption experiments with squash plants in water cultures indicated that little chlorate is absorbed from high-nitrate cultures, whereas more chlorate is absorbed and accumulated in the xylem sap in low-nitrate cultures.

"Since in most soils fertility, as denoted by the production of crops and roadside plants, is determined by nitrate concentration, plant growth may be used in predicting response to chlorate applications. In highly fertile soils costly experimentation with chlorates may be avoided and a program using carbon bisulfide or cultural or cropping practices substituted."

Summary of results of seed and legume inoculant inspection for 1938, J. G. FISKE (*New Jersey Stat. Bul.* 658 (1938), pp. 22).—Seed dealers in New Jersey from whom 2,211 official samples of crop and vegetable seed and seed mixtures were collected in 1938 are listed with compliances and violations, and crops, inoculation, and number of organisms are shown for 41 official samples of legume inoculants.

HORTICULTURE

[Horticultural studies by the New Haven Station] (*Connecticut [New Haven] Sta. Bul.* 421 (1939), pp. 20, 38, 39-41).—Included are brief progress statements on sand culture of seedling and mature plants and breeding of sweet corn, garden beets, peppers, tomatoes, and squash.

[Horticultural studies by the Kentucky Station] (*Kentucky Sta. Rpt.* 1938, pt. 1, pp. 18, 19).—Included are reports on variety tests of fruits and vegetables and on a comparison of strawy manure mulch with nitrate of soda for red raspberries.

[Horticultural studies by the Massachusetts Station], K. J. KUCINSKI, W. S. EISENMENGER, L. H. JONES, E. BENNETT, H. J. FRANKLIN, H. F. BERGMAN, W. E. TRUBAN, H. E. WHITE, C. L. THAYER, R. M. KOON, G. GRAVES, H. S. TIFFANY, W. H. LACHMAN, G. B. SNYDER, R. E. YOUNG, P. W. DEMPSEY, A. P. TUTTLE, J. K. SHAW, L. SOUTHWICK, A. P. FRENCH, O. C. ROBERTS, J. S. BAILEY, F. SHAW, W. H. THIES, and R. A. VAN METER. (Partly coop. U. S. D. A.). (*Massachusetts Sta. Bul.* 355 (1939), pp. 14, 28, 29, 35, 48, 44, 68-70, 77-91).—Among investigations the progress of which is discussed are winter cover crops for onion fields; water culture of plants and methods of watering potted plants; effect of storage and processing on the carbohydrates of onions; effect of the September 1938 hurricane on cranberry bogs; flower and fruit production in the cranberry; breeding snapdragons for quality and disease resistance; effect of temperature on forcing lilies; effect of soil temperature, plant nutrients, soil reaction, and light on gardenias; propagation of the geranium; testing of packeted seeds; breeding and testing of perennial asters; propagation of clematis, delphinium, and beach plums; testing of hardy ornamentals; shape indexes of tomatoes; breeding of sweet corn and tomatoes; culture of the pepper; soil preparation for vegetables; asparagus culture and improvement; culture of trellised tomatoes; vegetable breeding and selection; influence of various clonal rootstocks on the apple; tree characters of fruit varieties; genetic composition of the peach; cultural and fertilizer requirements of apple trees; testing of fruit varieties; bud mutations in the apple; fruit-bud formation in the strawberry; nutritional requirements of the highbush blueberry and blueberry culture; pollination of the blueberry; causes of premature dropping of the McIntosh apple; and supplemental sun-coloring of the apple.

[Horticultural investigations by the Puerto Rico College Station], F. MÉNDEZ, J. GUISCARÉ ARRILLAGA, L. A. GÓMEZ, E. MOLINAR SALÍS, A. RIOLANO, L. A. SERRANO, J. SIMONS, and C. J. LAVELLE (*Puerto Rico Col. Sta. Rpt.* 1938, pp. 54-61, 62, 63, 65, 66, 72, 77, 80, 82, 83-85, 85-89, 90, 91, 98, 107, figs. 6).—Brief discussions are presented on the progress of studies of new dwarf coconuts, management of coffee plantations, fertilizers for coffee, propagation of coffee, effect of light intensity on the coffee plant, growth habits of coffee roots, the Columnaris variety, abscission of blooms in coffee, fertilizer needs and variety tests of garden peas, fertilizer requirements of the cucumber and pepper, citrus rootstocks, citrus fertilizers and irrigation, and varieties of bananas, citrus, mangoes, avocados, and papayas.

[Horticultural studies by the Wisconsin Station], L. LANGOEN, R. H. ROBERTS, O. B. COMBS, J. G. MOORE, P. H. HORNBERG, F. L. MUSBACH, E. TRUOG, N. P. NEAL, R. H. ANDREW, and E. J. DELWICHE (*Wisconsin Sta. Bul.* 443 (1939), pp. 9-13, 51-53, 77-81, fig. 1).—Among studies discussed are those dealing with the soil management of orchards; variety testing of raspberries, muskmelons, lettuce, lima beans, tomatoes, and other vegetables; transplanting of tomatoes; fertilizer requirements of peas, beets, sweet corn, and tomatoes; pro-

duction of hybrid sweet corn varieties; and varietal and cultural trials of canning peas.

[Horticultural studies by the Wyoming Station] (*Wyoming Sta. Rpt. 1938*, pp. 31, 33, 34, 38, 40).—Brief mention is made of the results of variety trials with bush fruits and plums, of comparisons of fallowing and irrigation of gardens, and of the improvement of garden beans by plant selection.

Growing plants in nutrient solution, L. J. ALEXANDER, V. H. MORRIS, and H. C. YOUNG (*Ohio Sta. Spec. Cir. 56 (1939)*, pp. [1]+17, figs. 5).—Beginning with a brief discussion upon the physiology of plant growth, general information is offered on methods of nutrient-solution culture, construction of the tanks, composition of the essential solutions, and some of the limitations and possibilities of this type of plant growing.

Containers for fruits and vegetables, L. C. CAREY (*U. S. Dept. Agr., Farmers' Bul. 1821 (1939)*, pp. 64, figs. 53).—This publication, superseding those noted earlier (*U. S. R.*, 52, p. 206; 61, p. 339), describes the types of containers most commonly used for shipping various commodities. Federal standards are in force for barrels and for several types of baskets and hampers, but most fruits and vegetables are said to be handled in containers such as crates, boxes, cartons, drums, and sacks for which no standards have been established. The existing Federal legislation is reviewed, and the importance and potential benefits of standardization are set forth.

Induced parthenocarp of watermelon, cucumber, and pepper, C. WONG. (*Mich. State Col.*). (*Science*, 89 (1939), No. 2314, pp. 417, 418).—Stating that natural parthenocarp occurs very rarely in the National Pickling cucumber, the author reports that naphthalene acetic acid applied either in lanolin paste or in aqueous solution produced parthenocarpic fruits. In the watermelon, fruits were induced by treating the cut styles with lanolin paste or with aqueous solution. The resulting fruits were seedless and variable in shape, but of normal flavor. Satisfactory results were secured with the Harris Wonder pepper, both with lanolin paste and with aqueous solution.

A comparison of some asparagus varieties in California, H. A. JONES and G. C. HANNA. (*U. S. D. A. and Calif. Expt. Sta.*). (*Canner*, 88 (1939), No. 19, pp. 18, 20, 21).—In a 12-yr. test at Davis, Calif., significant differences in yield, size and number of spears, and in earliness were established between varieties and strains of asparagus. Mary Washington produced the highest yields and the largest spears of any variety under trial. Within a single variety strains differed significantly, for example one Martha Washington strain outyielded the other by an average of 657 lb. per acre per year.

Placement of fertilizer for Henderson bush lima beans in Virginia, M. M. PARKER and G. A. GUMINGS (*Coop. U. S. D. A.*). (*Virginia Truck Sta. Bul. 99 (1938)*, pp. 1557-1578, figs. 5).—Applications by different methods of 500 and 1,000 lb. per acre of a 4-10-8 NPK mixture to Henderson bush lima beans growing on Saxapfuns sandy loam showed the desirability of placing the fertilizer in narrow bands from 2 to 3 in. at each side of the seed row and from 1 to 2 in. below the seed level. The greatest profusion of blooms and rapidity and uniformity of plant growth resulted from placement 2 in. to each side of the row and 1 in. below the seed level. This method also produced the earliest yield and the largest total yield. The use of 1,000 lb. of fertilizer per acre gave larger yields than 500 lb., but the increments were not sufficient to offset the cost of the additional fertilizer. Fertilizers mixed with the soil or broadcast immediately before planting were more or less injurious, depending upon the thoroughness of incorporation and the amount of soil moisture present during germination. Fertilizers placed on the top of the row became

harmful under certain conditions of precipitation occurring during the germination period. The machine used in sowing the seed and distributing the fertilizer is described.

Influence of various factors on the shape of beet roots, R. C. THOMPSON. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 58 (1939), No. 10, pp. 733-745, figs. 2).—Variations in shape of beet roots due to various factors were studied by means of three numerical indexes. The shape indexes were found to vary with size of roots, soil texture, and seasonal conditions as determined by dates of planting and harvesting. Variation in fertility level failed to give significant changes in shape. In genetically pure strains of beets, variation in shape due to environment is not great except under wide extremes of soil texture and seasonal conditions.

The relation of cabbage hardness to bound water, unfrozen water, and cell contraction when frozen, J. LEVITT. (Univ. Minn.). (*Plant Physiol.*, 14 (1939), No. 1, pp. 93-112, fig. 1).—At any given temperature, hardened cabbage plants had less water withdrawn in the form of ice than did the unhardened. At a temperature which caused practically complete killing of unhardened plants, they retained 3.5 times as much water in the unfrozen state as did the hardened plants frozen to produce the same amount of injury. The amount of nonosmotically bound water in hardened plants was very small, and, although larger than that of unhardened plants at the same temperature (-5.6°C.), was nevertheless smaller when the two groups were compared at their respective critical freezing temperatures. In this case, more ice was formed per gram fresh weight in the hardened than in the unhardened plants. Cabbage hardness, therefore, is not simply a matter of resistance to dehydration, nor directly related to the amount of ice that forms, but rather is due to some increased ability to resist the effects of freezing.

A fertility program for celery production on Everglades organic soils, J. R. BECKENBACH (*Florida Sta. Bul.* 533 (1939), pp. 39, figs. 9).—Of various trace elements required for celery growing on Everglades organic soils, Mn is said to be most commonly deficient. Zn, Cu, and B are also often present in inadequate amounts, and recommendations for supplying these four elements are given. Depth of the water table was found highly important, with the suggestion that except at the time of sowing the seed and setting the plants the table should be kept at a depth of from 16 to 24 in. throughout the growing period. Despite the fact that available N is being released in peat soils at all times, it was found, on the basis of eight successive yearly tests, that mixtures containing P and K plus 3 percent N gave higher yields than when the N was omitted. In 7 of the 8 yr. the increased yields were sufficient to more than pay for the N. The importance of K was shown in the fact that crops grown without this element were practically failures. On a 5-yr. average, 51 more crates per acre per year were produced with muriate of potash than with sulfate of potash. In comparing 6, 12, and 18 percent of K used with other materials, it was found that from the standpoint of both yield and net profit per acre 12 percent was most desirable. A 6 percent phosphate fertilizer properly balanced with N and K and applied at the rate of 1 ton per acre before setting the plants was considered nearly optimum where celery is grown annually and the plant trimmings returned to the soil. The ratio of the three elements N, P, and K should be in the order of 1:2:4. The author advises that celery should not be planted on freshly broken virgin soils, but rather should follow some crop of lower fertilizer requirements. Suggestions for fertilizer treatment of mucks in various stages of development are given.

Mushroom casing soil in relation to yield, E. B. LAMBERT and H. HUMPHRED (U. S. Dept. Agr. Cir. 509 (1939), pp. 12, figs. 2).—With plots replicated in most

cases five times it was found that, in general, heavy soils gave larger yields than did those of sandy types. Clay loams appeared preferable wherever their physical condition was such that they did not puddle or cake. For applications of the casing layer, 2 or 3 weeks after spawning was apparently the best time. Soil approximately neutral in reaction gave better results than very acid or very alkaline material. The thickness of the casing was not important within reasonable limits, but a 1-in. layer appeared desirable. Heat sterilization of the soil caused marked reductions in yield in certain instances.

Use of the tenderometer in forecasting grades of Alaska peas for canning, E. P. WALLS and W. B. KEMP. (Md. Expt. Sta.). (Canner, 88 (1939), No. 11, pp. 20, 22).—Based on 1938 studies of approximately 1,200 samples of either run-of-pod peas or of various sieve sizes, two sets of tables and formulas are presented for forecasting maturity grades by the use of the tenderometer.

Vegetative reproduction of squash types, W. K. BAILEY. (P. R. Expt. Sta.). (Science, 89 (1939), No. 2302, pp. 128, 129).—Vigorous five- to seven-node cuttings with swollen root buds at several nodes were rooted successfully and fruited earlier than plants grown from seed.

Suggestions to tomato growers, J. S. JOFFE and V. A. TIEDJENS (New Jersey Sta. Cir. 391 (1939), pp. 4).—This includes brief practical suggestions, as to soils, fertilizers, cover crops, growing of plants, control of pests, etc.

Experiments with growth controlling substances.—II, Response of fruit tree cuttings to treatment with synthetic root-forming substances, H. L. PEARSON (East Malling [Kent] Res. Sta. Ann. Rpt., 26 (1938), pp. 157-166, pls. 2).—In continuation of this series (E. S. R., 78, p. 484), numerous trials with softwood cuttings of several varieties of pear, quince, apple, plum, and cherry showed that with suitable material root formation was accelerated and increased following treatment with indolebutyric and α -naphthalene acetic acid. The status of the mother plants at the time the cuttings were taken was important. In general, indolebutyric acid promoted the more fibrous root system. Subsequent treatment with vitamin B₁ did not increase successful rooting but did promote more vigorous subsequent growth in the rooted plants. No well-defined stimulation was secured from treating hardwood cuttings taken in autumn.

Establishing the orchard, T. J. TALBET (Missouri Sta. Cir. 202 (1939), pp. 23, figs. 9).—Included is general information on the selection and handling of nursery stock, selection of sites, preparation of soil, planning and planting the orchard, pruning, cultural practices, protection from pests, etc.

Pruning fruit plants, R. J. BARNETT and G. A. FILINGER (Kans. Sta. Cir. 197 (1939), pp. 26, figs. 14).—This revision of the earlier noted pamphlet (E. S. R., 63, p. 446) presents in a like manner general information on the principles and practices of pruning fruit trees, with specific information on the various individual fruits.

Spraying program and pest control for fruit crops (Ohio Sta. Bul. 599 (1939), pp. 52, figs. 19).—With spray calendars for specific fruits, general information is supplied on spray materials, spraying equipment, and practices; on dusting; and on the treatment of various troubles (such as fire blight, cedar rust, peach borers, and rodents) not handled by spraying procedures.

Note on the effect of the variety of stock used to provide the intermediate stem-piece in some double-worked apple trees, M. C. VYVYAN (East Malling [Kent] Res. Sta. Ann. Rpt., 26 (1938), pp. 148-156, figs. 3).—At the end of 10 yr., Stirling Castle trees worked on Malling XII with intermediate pieces of Malling II in one case and of Malling XII in the other showed no obvious differences in average tree size. Measurements failed to show any significant effect of the intermediate piece on the vigor of the tree, whether expressed as wood growth, final weight, or rate of growth. However, by the

ninth year there were significantly more fruit buds per tree and per meter of wood on the Malling II/XII than on the Malling XII/XII trees. The two types of tree could readily be distinguished by the differential taper of the upper part of the trunk and by the swelling above the upper union in the II/XII group.

Studies in nursery technique: Shield budding—treatment of inserted buds with petroleum jelly. R. J. GARNER and D. H. HAMMOND (*East Malling [Kent] Res. Sta. Ann. Rpt.*, 26 (1938), pp. 115-117).—Malling IX clonal stocks shield-budded with Cox Orange and tied with rubber strips or with raffia were, in part, smeared with petroleum jelly. The jelly treatment materially increased the bud "take," particularly in the raffia-bound lot. The use of petroleum jelly is inexpensive and is recommended for trial wherever unsatisfactory takes occur.

Are there different critical oxygen concentrations for the different phases of root activity? D. BOXTON, J. DE VILLIERS, and W. REUTHER (Cornell Univ.). (*Science*, 88 (1938), No. 2294, pp. 569, 570).—Controlled greenhouse studies with apple seedlings suggested that with O_2 in the soil atmosphere at 3 percent, roots subsist but grow slowly if at all. At 1 percent O_2 , roots apparently lost weight. There was some indication that a high O_2 level may be necessary for the initiation of new roots from the existing root system. Roots of the apple seedlings did not grow normally at concentrations of O_2 below 10 percent, even though there was considerable growth between 5 and 10 percent. It was observed that the ash content in percentage of dry weight of apple seedlings decreased uniformly as the O_2 percentage decreased from 15 percent.

Causes and effects of size differences in apple trees in the nursery. F. C. BRADFORD and L. JOLEY (*Michigan Sta. Tech. Bul.* 163 (1939), pp. 54, figs. 8).—Of several factors concerned in size differences in nursery apple trees, the size of the apple from which the seeds were collected was not related per se to seedling size. Seed from small apples produced seedlings as vigorous as those grown from seed from large apples of the same variety. In a few instances, vigor of seedlings of the same variety varied with the pollen parent utilized, but in no case was the difference sufficient to affect performance in the nursery. Seedlings of diploid varieties, such as Jonathan, McIntosh, Yellow Bellflower, Northern Spy, and Wealthy, were as vigorous as those from the usual commercial sources.

Individual differences observed in the seedling year were maintained through the second year, also in the budded whip, and for the first 2 yr. in the orchard. The period of maximum growth and the time of cessation of growth were not affected by the size of the seedling on which the whip was budded, but the amount of growth was closely related to the size of the seedling. Trees budded on the smaller seedlings of diploids grew somewhat better than those budded on seedlings of triploids, but it was noted that their growth resembled that of trees on seedlings of triploids more closely than it did that of the trees on larger seedlings of diploids.

The authors conclude that the evidence at hand does not warrant any present affirmation or negation of genetic influences as the principal cause of enduring differences found among nursery trees.

Permanence of size differences in orchard trees. R. E. MARSHALL (*Michigan Sta. Quart. Bul.*, 21 (1939), No. 4, pp. 265-277, figs. 2).—Data secured incidental to a long-time pruning study in an apple orchard including Oldenburg, Grimes Golden, Stayman Winesap, Baldwin, and Northern Spy varieties indicated that on the average the small trees at the time of planting remained smaller in size as measured by rate of trunk growth and top volume increment. Observations on the annual rings of filler trees removed at the end of 15 yr.

gave similar evidence, namely that the smallest and largest trees at the time of planting retained their relative positions at the end of the period.

Low temperature injury to fruit blossom.—I, On the damage caused to fruit blossom by varying degrees of cold, C. P. FIELD (*East Malling [Kent] Res. Sta. Ann. Rpt.*, 26 (1938), pp. 127-138, figs. 5).—Observations on flowers of two apple varieties, crab "A" and Court Pendu Plat, following exposure to low temperatures in constant temperature chambers showed injury comparable to that occurring in the orchard under natural conditions. Temperatures at or below 29° F. caused damage proportional to the duration of the exposure. Slow cooling retarded the appearance of injury, but in general the time taken in thawing was not a factor. Wetting the blooms hastened injury. Attempts to harden blooms by holding them at 38° and 34° had little effect. Of materials injected into the shoots and flowers of the blackberry, only glycerin reduced susceptibility.

An apple irrigation trial, using soil moisture meters, W. S. ROGERS (*East Malling [Kent] Res. Sta. Ann. Rpt.*, 26 (1938), pp. 118-126, figs. 2).—In the case of 20-year-old Early Victoria apples on seedling crab roots planted alternately at 14 ft. with James Grieve on Malling V, water equivalent to 8.9 in. of rain applied in two treatments in June and July increased the size of fruits about 11 percent. Because of the nature of the soil, much of the water was lost in the underlying porous rock. Observations on James Grieve apples stored following irrigation showed no appreciable increase in bitter pit. There was, however, sufficient natural rainfall to prevent any of the control trees from reaching the wilting point.

Why some growers fail and others succeed with the same apple spray program, C. L. BURKHOLDER and G. E. LEIKER (*Indiana Sta. Cir.* 241 (1939), pp. 16, figs. 5).—Information is given on the control of various important orchard pests including scale insects, aphids, apple scab, and codling moth. Failure to control pests is believed to be more often due to improper methods than to variation in spray materials. In the case of codling moth, effective control of the first brood prevents the building up of large succeeding generations. Among recommendations for codling moth control are the screening of packing sheds, the concentration of sprays during the hatching period and when fruits are small, the timing of sprays by the use of moth traps, and pruning to open up the tree and careful spraying of the tops of the trees as well as the lower portions.

Sun-coloring apples, C. W. ELLENWOOD and T. E. FOWLER (*Ohio Sta. Bim. Bul.* 198 (1939), pp. 39-46, figs. 2).—Stating that sun coloring is not a new proposition, despite renewed interest, the authors discuss the results secured with apples placed on straw mulch, on wire racks, and directly in cold storage. The most striking color change secured from sun exposure was in the case of McIntosh, with good results in the case of Northern Spy and others. Although there was some softening of apples in the open, there was no significant loss in keeping quality provided the fruit was stored immediately following sun coloring. The use of mulch rather than racks appeared more practical. Sun coloring permitted the entire harvesting of one tree crop at one time.

Pear rootstocks from seed.—I, Experiments on methods of germinating pear seeds; II, Studies on the variation in seedling pear trees, H. M. TYDEMAN (*East Malling [Kent] Res. Sta. Ann. Rpt.*, 26 (1938), pp. 103-114, pl. 1).—Trials with various rootstock varieties indicated that pear seeds require a short rest period under cold conditions to insure satisfactory germination. Placement of seed in an outdoor pit from early November to February gave good results. There were no consistent differences between the several clones with respect to germination. There was some indication that the removal of the mucilaginous film from the seeds by washing in water facilitated their germination when sown immediately after separation from the fruits.

Botanical studies in part 2 on the seedlings grown from open-pollinated seed from East Malling selected Free Pear AI stock and from seed collected in North Caucasus showed the East Malling group to be more variable than the North Caucasus, due, apparently, to the greater opportunities at East Malling for cross-fertilization.

Effect of ethylene on certain chemical changes associated with the ripening of pears, E. HANSEN. (Oreg. Expt. Sta.). (*Plant Physiol.*, 14 (1939), No. 1, pp. 145-161, figs. 2).—Bartlett and Anjou pears gathered at approximately 2-week intervals beginning 5 weeks after blooming and extending beyond the usual commercial harvest season were placed in jars in which was maintained a concentration of 1 part in 1,000 by volume of ethylene. As a control, other fruits were kept in ventilated jars to prevent gas accumulation. Fruit of the first picking produced barely enough ethylene to induce detectable epinasty of potato leaves. Untreated fruits of the first picking gained no soluble pectin in 12 days, whereas ethylene-treated fruits showed a marked increase at the end of 8 days. The changes brought about by ethylene were identical to those taking place during the normal ripening. Later harvests showed increasing ethylene output. There was an increased rate of starch hydrolysis, higher sugar content, more rapid change of protopectin to pectin, and increased respiratory activity in ethylene-treated fruits. The increase in the rate of softening in ethylene-treated fruits was correlated definitely with increase in rate of pectin changes. Ethylene effects were shortest in duration with sugar and starch changes and longest with pectin reactions and respiration.

A further experiment in thinning the fruit of Victoria plums, A. C. PAINTER and B. L. WATES (*East Malling [Kent] Res. Sta. Ann. Rpt.*, 26 (1938), pp. 139-144).—Comparing the effects of removal of fruits so that those remaining were approximately 1 in. apart in one case and 2 in. in another, the authors found that the more heavily thinned trees produced considerably more large-sized fruits and far less small fruits. Total yields were decreased by the heavy thinning, which also tended to hasten maturity. The market quality of the fruits of any given size was much the same from both treatments.

The influence of certain hormone-like substances on the rooting of hardwood blueberry cuttings, S. JOHNSTON (*Michigan Sta. Quart. Bul.*, 21 (1939), No. 4, pp. 255-258).—In the hope of reducing the time required to secure good root development in hardwood blueberry cuttings, cuttings of Rubel, Adams, Cabot, and Pioneer were treated with various concentrations of Hormodin A and Auxilin. The results were such as to lead to the conclusion that the materials under trial were of little value in hastening root formation in the blueberry.

Grapes in Arizona, A. H. FINCH, R. H. HILGEMAN, H. F. TATE, R. B. STREETS, and L. P. WEHRLE (*Arizona Sta. Bul.* 162 (1939), pp. 245-292, figs. 19).—This paper, presented in five parts which deal, respectively, with some general aspects, grape varieties for Arizona, grape pruning, grape diseases, and grape insects in Arizona, consists for the most part of information of a general nature, but data on varieties are based on extensive trials.

Boron in citrus nutrition in Florida, A. F. CAMP. (Fla. Expt. Sta.). (*Citrus Indus.*, 20 (1939), No. 2, pp. 6, 7, 18).—Following a review of the literature, the author points out the fact that boron, although an essential nutrient, may easily become a toxic factor. An instance of possible deficiency in a Florida citrus grove is discussed advisedly pending the results of experimental studies undey way.

Rootstock influence on the composition of citrus fruits, R. W. HODGSON and E. R. EGGER. (Univ. Calif.). (*Calif. Citrog.*, 23 (1938), No. 12, pp. 499, 531).—Fruits taken from young bearing trees of Valencia and Washington Navel oranges, Marsh grapefruit, Lisbon and Eureka lemons, and Bearss lime, all

budded on sour orange, sweet orange, rough lemon, grapefruit, and trifoliolate orange roots, were studied as to composition. Trifoliolate orange, the most dwarfing of the several stocks, produced the highest percentage of soluble solids in the juice in all cases. Rough lemon, the most vigorous stock, produced the lowest soluble-solids content. Both species influenced acid content of the fruits in the same manner as soluble solids. Paradoxically both stocks had an approximately equal effect in producing a high soluble solids:acid ratio in the juice.

Progress report of lemon rootstock experiments, L. D. BATHURST and H. J. WEBBER. (Calif. Citrus Expt. Sta.). (*Calif. Citrog.*, 24 (1939), No. 5, pp. 160, 161, 190, 191).—In 1927 two experimental rootstock orchards were established, one at Riverside and one at Fillmore, Calif. All the trees of each stock were propagated from a single parent tree, and all the buds of the two varieties used, Eureka and Lisbon, were taken from individual trees. Among observations at the end of 12 yr. of work was one that the sweet orange has proved superior to all other rootstocks tested. The sour orange and the rough lemon stocks were apparently much better adapted to light than to heavy soils. On sour orange roots in heavy soil, both Eureka and Lisbon showed a large percentage of trees affected with lemon decline. On light sandy soils, both varieties on sour orange showed very little evidence of this defect. The results showed that lemon decline is apparently a rootstock and soil-adaptation problem in its broadest sense.

A method for the treatment of cuttings and roots of the pecan with root-inducing chemicals, C. L. SMITH and L. D. ROMBERG. (U. S. D. A.). (*Plant Physiol.*, 14 (1939), No. 1, pp. 177, 178).—The insertion in holes bored in the cutting or root of wood toothpicks which had been immersed in an alcohol solution of indolebutyric acid for 24 hr. was successful in inducing root formation. The amount of chemical per toothpick was readily adjusted by changing the concentration.

Composition and rooting of American holly cuttings as affected by treatment with indolebutyric acid, N. W. STUART and P. C. MARSH. (U. S. D. A.). (*Amer. Soc. Hort. Sci. Proc.*, 34 (1937), pp. 839-844, fig. 1).—In proper concentrations and durations of treatment, indolebutyric acid was found effective in hastening the rooting of holly cuttings. The stems of cuttings that had been treated maintained a higher percentage of sugar than the untreated until extensive root growth occurred. The gradual decrease in starch content of the leaves was similar in both treated and untreated cuttings. The results with wounded holly cuttings indicated that slicing of the bark or slitting of the stems, as a supplementary treatment, may be an important practical aid in increasing the effectiveness of the application of growth substances. Indolebutyric acid treatment of cuttings that had been held untreated in the propagating bed for 76 days without rooting induced a vigorous rooting response within 21 days, with the wounded cuttings again giving much the better response.

Gravel culture of flowering plants in the greenhouse, A. WAGNER and A. LAURIN (*Ohio Sta. Bmo. Bul.* 198 (1939), pp. 47-52, figs. 3).—Gravel culture with nutrient solutions is said to have numerous advantages, including the absence of watering, weeding, cultivation, fertilization, and changing of the soil. In addition, the type of growth can be more or less controlled by changing the concentrations of nutrients. Soil-borne pests and diseases are absent, and in some cases better-quality blooms are produced. The authors discuss nutrient solutions, methods of application, and some of the results secured with roses and chrysanthemums. Among crops grown successfully were roses, carnations, chrysanthemums, sweet peas, snapdragons, begonias, and marigolds.

New chrysanthemums, F. L. MULFORD (*U. S. Dept. Agr. Cir.* 528 (1939), pp. 8, figs. 4).—Descriptive notes are presented on 12 newly named hardy

chrysanthemums resulting from rigorous selection from among thousands of open-pollinated seedlings.

Growth and flowering of the gladiolus: Influence of certain morphological and physiological characteristics of the corms, L. C. GROVE (Iowa Sta. Res. Bul. 253 (1939), pp. 81-112, figs. 7).—Over a 2-yr. period comparisons were made of the growth and flowering of high- and low-crowned gladiolus corms of nine varieties, including *primulinus*, *grandiflorus*, and hybrid types. In addition, chemical studies were made of the corms of the Excellence variety grown in the field and in darkness. The results of the morphological studies indicated that no one shape or size of corm can be associated with any definite qualitative flowering capacity. In most varieties, low-crowned corms completed their emergence from the soil in less time and produced taller spikes than did the high-crowned. Low-crowned corms always produced greater total leaf area, more spikes, and a greater number of florets per corm than did the high-crowned.

As to chemical composition, the size and shape of the corm did not appear to be associated with significant differences in the percentages of reserve materials. High-crowned corms contained a higher percentage of starch and sugars at the time of planting and for 4 weeks thereafter. However, because of their larger size, the low-crowned corms contained greater total reserves and are believed preferable for forcing where light conditions are not of the best. The author suggests that the lower percentages of reserves in the low-crowned corms in the early growth stage is due to the greater number of shoots. This assumption was confirmed by the fact that analyses prior to sprouting showed no significant difference in percentage of sugars in the two corm types. Nearly one-half of the total N reserves in the corms was exhausted within 2 weeks after planting, suggesting the need of supplying N at an early stage on soils low in this element. The seasonal trend in the disappearance of food reserves from mother corms showed a rapid decrease during the first 6 weeks.

Development and care of lawns, H. F. MAJOR (Missouri Sta. Cir. 204 (1939), pp. 12, figs. 4).—General information is offered on the construction of new lawns and maintenance of old lawns, with suggestions as to fertilization, seeding, and general management.

FORESTRY

A modified tree classification for use in growth studies and timber marking in Black Hills ponderosa pine, E. M. HOENIBROOK. (U. S. D. A.). (Jour. Forestry, 37 (1939), No. 6, pp. 483-488, figs. 3).—Keen's tree classification, with certain modifications, was found a satisfactory criterion of the relative growth capacities of Black Hills ponderosa pine, both in uncut and selectively cut stands. The mean difference in diameter growth between age classes and between vigor classes was found highly significant. In general, the effect of average release by selection cutting on diameter growth was to accelerate the growth rate equivalent to that of trees in uncut stands having the same vigor class but one age class younger.

The decagon for vegetation studies, M. CHURLEY. (U. S. D. A. and Univ. Ariz.). (Jour. Forestry, 37 (1939), No. 6, pp. 492, 493, figs. 2).—Herein is offered a description of a method found useful in estimating the density of ground covers, particularly grasses and low-growing shrubs. The method was found particularly promising in making pasture surveys where a considerable number of temporary plats are located at random over the range.

An extension rod for measuring tree heights, J. E. HETZEL. (U. S. D. A.). (Jour. Forestry, 37 (1939), No. 6, pp. 494, 495, fig. 1).—A description is given of an extension rod consisting of four 8-ft. sliding sections which was found useful under widely varying conditions for measuring the height of forest trees.

Increment core handling, H. FRETZ. (Univ. Calif.). (*Jour. Forestry*, 37 (1939), No. 6, pp. 491, 492, fig. 1).—A description is offered of a field book designed for handling increment cores in the field and transporting them safely to the laboratory.

A soil boring tool for frost depth determination, B. C. GOODELL. (U. S. D. A.). (*Jour. Forestry*, 37 (1939), No. 6, pp. 457-459, figs. 2).—A descriptive account is presented of a tool and method found useful in measuring the depth of frozen soil.

[**Studies in forest nurseries**], S. A. WILDE, J. C. KOPITKE, J. G. CADY, R. WITTFENKAMP, H. M. GALLOWAY, E. L. STONE, and D. P. WHITE. (Partly coop. U. S. D. A. et al.). (*Wisconsin Sta. Bul.* 443 (1939), pp. 56-58, fig. 1).—Herein is discussed the progress of investigations relating to fertilizer and soil reaction needs of forest seedlings, use of liquid fertilizers, N starvation, methods of applying organic matter, use of alkaline raw humus, and factors such as damping-off disease in limiting the growth of pines in southern Wisconsin.

Root response to slash pine seedlings to indolebutyric acid, D. K. PLANK. (Univ. Fla.). (*Jour. Forestry*, 37 (1939), No. 6, pp. 497, 498, fig. 1).—In a limited trial there was observed, in the case of nursery-grown seedlings planted following treatment in a deep, moderately dry Norfolk sand, greater survival, much longer taproots, and better lateral root development in the treated trees than in the controls.

Why forest plantations fail, P. O. RUDOLF. (U. S. D. A. and Univ. Minn.). (*Jour. Forestry*, 37 (1939), No. 5, pp. 377-383).—In a study conducted by the Lake States Forest Experiment Station on the Huron National Forest, Mich., following the severe drought of 1936, it was observed that tree seedlings planted with roots predominantly in a single plane had a significantly greater mortality and made less height growth than did those with better root distribution. Heat and drought, particularly heat, accounted for most of the mortality. Neither soil acidity nor percentage of fine material in the soil showed any well-defined relationship to survival. It is suggested that, if planting is done in the open, some type of artificial shade should be provided, possibly by preliminary plantings of hardy shrubs or trees.

Which species shall we plant? E. SECREST (*Cent. States Forestry Cong. Proc.*, 1 (1930), pp. 203-213, fig. 1).—In this summary of Ohio experiences, the author discusses various species of forest trees with respect to their behavior, adaptability, seedling requirements, etc. Among conclusions reached are that mixtures of pine are more desirable than pure stands, that better survival follows the use of 4-year-old transplants than younger seedlings, that spacings closer than 6 by 6 ft. are not advisable, and that further research is needed to establish what species should be planted under various conditions.

[**Testing of forest tree species**] (*Wyoming Sta. Rpt.* 1938, pp. 31, 33).—The results of trials of numerous species are discussed.

A hardwood record, J. A. COPE. (Cornell Univ.). (*Jour. Forestry*, 37 (1939), No. 6, pp. 495-497).—Data are presented on the unusual growth and on thinning operations in an area in Monroe County, N. Y., clear cut in the winter of 1917-18.

A new alder, *Alnus rubra* Bong, *pinnatisecta* var. nov., T. J. STARKER. (Oreg. State Col.). (*Jour. Forestry*, 37 (1939), No. 5, pp. 415-417, fig. 1).—A brief technical description is given of a new variety of alder discovered a few miles northwest of Portland, Oreg.

Some physiological responses to close pruning of northern white pine, W. R. ADAMS and M. R. SCHNELLER (*Vermont Sta. Bul.* 444 (1939), pp. 26, pls. 8).—In the case of dominant and codominant trees in a 25-year-old white pine plantation spaced 6 by 6 ft. and pruned at various times throughout the

year, there were noted certain well-marked responses to the type and season of pruning as manifested in the character of the wound healing tissues. Deliberate cutting of the branch base of live branches resulted in callus formation in 98 percent of the cases; but where the branch base was not cut, less than 25 percent of the live branches, saw pruned without injury to the branch base or removed with point-cut pruners, showed callus at the end of the first growing season. Some advantage was gained, also, in injuring the branch base of excised limbs which had been dead for 3 or 4 yr. or less. There was little advantage in the case of older dead branches, because the living branch base was no longer present. Study of the callus arch formed showed it to consist initially of parenchyma cells produced rapidly to protect the phellogen and vascular cambium, which is later pushed aside by the formation of true corky cells by the phellogen and of xylem and phloem by the vascular cambium. The original parenchyma remains in contact with the resinous coating on the branch stub. At the end of the growing season the callus consisted mainly of regular phloem and xylem cells. Abnormal quantities of resin ducts were found in the xylem tissue in and directly adjacent to the callus. When pruning was delayed until June, 55 percent of the ring width consisted of thicker and darker-walled late wood cells. A narrow band of heartwood spreading from the branch heartwood to the outer margin of the branch stub occurred in all winter-pruned live branches.

Variation in the specific gravity of the springwood and summerwood of four species of southern pines, B. H. PAUL. (U. S. D. A. and Univ. Wis.). (*Jour. Forestry*, 37 (1939), No. 6, pp. 478-482, figs. 5).—The weight or density of the wood of any of the four southern pines (slash, longleaf, loblolly, and shortleaf) was found to vary over an exceedingly wide range. Within a single species, blocks of wood were found with double the density of others. Obviously, such variations exert a profound influence on strength, workability, shrinkage, and capacity to hold paint.

Mortality in cutover stands of ponderosa pine, G. A. PFARSON. (U. S. D. A. and Univ. Ariz.). (*Jour. Forestry*, 37 (1939), No. 5, pp. 383-387, fig. 1).—Of various agencies responsible for the death of ponderosa pines in the Southwest, wind and lightning were about equal and of primary importance, followed in descending order by mistletoe and insects, chiefly bark beetles. Data on several plats pointed consistently to the fact that the largest losses occur among the larger trees. Above a diameter of 23 in., there was a comparatively rapid increase in mortality rate.

Farm windbreak-handling trees to withstand drought conditions, M. J. GEORGE. (Coop. U. S. D. A.). (*North Dakota Sta. Bim. Bul.*, 1 (1939), No. 5, pp. 11-14, figs. 2).—As a result of experiences at the Northern Great Plains Field Station, information is offered on the establishment, maintenance, and function of windbreaks. Lack of moisture, said to be the major limiting factor, may be offset in part by so planting the trees as to retain the drifting snow.

Fire in land use and management, H. C. HANSON. (N. Dak. Expt. Sta.). (*Amer. Midland Nat.*, 21 (1939), No. 2, pp. 415-434).—Based on an exhaustive study of the literature, the conclusion is reached that fire has certain values, namely, in destroying debris and pests, clearing of land, and improvement of grazing conditions. However, in some cases fire causes irreparable damage, and research is needed to determine fully and accurately the values and losses.

Controlled burning in the western white pine type, K. P. DAVIS and K. A. KLEHM. (U. S. D. A.). (*Jour. Forestry*, 37 (1939), No. 5, pp. 399-407, figs. 3).—Admitting that controlled burning of slash and debris is a matter of question, the authors suggest that under certain conditions where adequate precautions are taken burning has a definite place in western white pine man-

agement. The details of burning technic are discussed, with observations on costs, subsequent treatments, etc.

Fire Control Notes, [April 1939] (*U. S. Dept. Agr., Forest Serv., Fire Control Notes*, 3 (1939), No. 2, pp. 11+36, figs. 20).—This quarterly periodical contains brief articles relating to equipment used in locating and controlling forest fires, organization of fire-fighting units, training of personnel, etc.

DISEASES OF PLANTS

Elements of plant pathology, I. E. MELHUS and G. C. KENT (*New York: Macmillan Co., 1939, pp. X+493, figs. 259*).—In this textbook the emphasis is placed on parasitism in disease processes and the principles relating to control measures, coupled with the condensation and omission of unnecessary morphological and mycological data. The objectives in choosing material were to meet the minimum needs in leading the student to appreciate the influence of plant pathology on human affairs, to acquire an understanding of health and disease in plants, to understand the phenomena of parasitism, and to acquire as much information as possible about the characteristics of diseases, their symptoms, causes, and control. Following the introduction, there are chapters on plant pathology and human affairs, the development of plant pathology, disease in plants, parasitism, the influence of environment on plant diseases, and the principles of control measures. With respect to specific diseases, nine chapters deal, respectively, with diseases caused by Phycomycetes, bacteria, viruses, Ascomycetes, Fungi Imperfecti, Basidiomycetes, seed plants, nematodes, and nonparasitic agents. A glossary, a bibliography, and an index are provided.

Studies on the nutrition of fungi.—II, Effect of inoculum on the growth of the colony, L. H. LEONIAN and V. G. LILLY. (*W. Va. Expt. Sta.*). (*Phytopathology*, 29 (1939), No. 7, pp. 592-596, figs. 2).—Continuing this study (*U. S. R.*, 80, p. 21), by use of thiamin and dextrose as test substances and *Phycomyces blakesleeanus* as test organism it was found that for all practical purposes the amount of these substances in the average size inoculum (3 by 2 mm.) is not significant for the initiation and growth of the new colony. At least 100 times the optimum amount of thiamin must be used before an inoculum piece of such size can show even a slight effect, and 1,000-10,000 times the optimum before a significant growth results. An agar disk 5 mm. in diameter and containing 20 percent dextrose failed to influence growth, but when the diameter was increased to 10 mm. a significant growth followed.

Handbook of virus investigation.—I, The development of virus investigation and its problems, the morphology of different viruses, the culture of different viruses outside their hosts, the biochemistry and biophysics of viruses, edited by F. M. BURNET, R. DOERR, W. J. ELFORD, G. M. FINDLAY, M. HATTINGER, C. HALLAUER, M. KAISER, and W. M. STANLEY (*Handbuch der Virusforschung*, edited by R. DOERR and C. HALLAUER. 1. *Heft, Die Entwicklung der Virusforschung und ihre Problematik, Morphologie der Virusarten, die Züchtung der Virusarten aussserhalb ihrer Wirte. Biochemistry and Biophysics of Viruses*. Wien (Vienna): Julius Springer, 1938, pt. 1, pp. XII+546, figs. 77).—This is a monographic compendium containing sections in German or English by various contributors and with copious bibliographies.

Methods for virus studies, H. DA ROCHA-LIMA, J. REIS, and K. SILBERSCHMIDT (*Methoden der Virusforschung. Handbuch der biologischen Arbeitsmethoden, Abt. XII, Teil 2, Heft 8. Berlin and Wien (Vienna): Urban & Schwarzenberg, 1939, XII, pt. 2, No. 8, pp. 1135-1489, figs. [54]*).—This is a monographic handbook of methods for use in the investigation of virus diseases of both plants and animals, with literature references at the end of the individual sections.

The nomenclature of plant viruses, G. C. AINSWORTH (*Chron. Bot.*, 5 (1939), No. 2-3, pp. 193, 194).—A discussion with proposal of a system of designating virus types and strains.

The ultracentrifugal analysis of the latent mosaic virus protein, R. W. G. WYCKOFF (*Jour. Biol. Chem.*, 128 (1939), No. 3, pp. 729-733, figs. 6).—In previously reported studies (e. g., *E. S. R.*, 78, p. 803; 80, p. 358), sedimentation diagrams have been made of several virus protein solutions at a wide variety of pH values and it has been demonstrated that in each case the virus protein molecule and the infectivity of the virus have the same range of pH stability. The same type of study is here reported for the latent mosaic virus protein, including detailed descriptions of the methods and results.

Bacterium tumefaciens [trans. title], L. MONTEMARTINI (*Bol. Ist. Sieroterap. Milan.*, 18 (1938), No. 9, pp. 551-588).—This comprehensive review (about 12 double-column pages of references) treats the subject matter mainly under identification and synonymy of the bacteria concerned, the question of a homogeneous species or of diverse races, the pathogenesis of the disease and its gross and microscopical pathology, the hosts (including a list), its geographical distribution, its control, and comparisons between the *B. tumefaciens* tumors of plants and animal tumors.

Bacterial leaf-spot diseases, J. J. REID, M. A. FARRELL, and D. E. HALLEY. (Pa. Expt. Sta.). (*Science*, 89 (1939), No. 2320, pp. 566, 567).—The authors claim on experimental evidence that the *Phytophthora tabaci* of tobacco wild fire is a transitory physiological adaptation of the saprophytic *Pseudomonas fluorescens*, and that field infection is due not to the mere presence of this ubiquitous organism but to its association with improper host nutrition. Grower practices thought largely responsible for the severity of tobacco leaf spot infections are, in decreasing importance, the incorporation of large amounts of organic nitrogen in the soil, use of too much nitrogen and too little potash fertilization, excessive lime applications, and in some cases poor tilth. The authors claim that practices tending to produce a normally resistant plant of high quality and good yield are rotations reducing the amount of organic nitrogen in the soil, preliminary rotting of all manure and use of liberal amounts to improve tilth and aid potash intake, suitable applications of fertilizer with inorganic in excess of organic nitrogen, and suitable cultivation to insure maximum uptake of potash and other essentials.

Subsidiary studies of several other *Phytophthora* leaf spot diseases gave comparable results, thus emphasizing the basic similarity of bacterial leaf spot diseases and the relation of the pathological condition to the improper nitrogen-mineral balance in the host.

Nutrition and bacterial virulence, G. MITCALFE (*Chron. Bot.*, 5 (1939), No. 2-3, pp. 189, 190).—A review with citations, relating to phytopathogenic forms.

The development of *Mycosphaerella berkeleyi*, W. A. JENKINS. (Ga. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 58 (1939), No. 8, pp. 617-620, pl. 1).—Structural and developmental details of the spermatogonia and perithecia of *M. berkeleyi* are said to differ from those of *M. arachidicola*, principally in the greater amount of stroma surrounding the fruit bodies, longer sterigmata on the spermatial mother cells, greater number of archicarpes in the young perithecia, greater amount of fertile tissue in the base of the perithecium, in the origin of periphyses, and in the tardiness of ascospore discharge. In addition, as previously stated (*E. S. R.*, 79, p. 350), the two fungi produce different symptoms on their mutual host (peanut) and differ in type of conidial fruitifications, host relationships, culture characteristics, and size of ascospores.

Methods of determination of physiologic races of *Rhizoctonia solani* on the basis of parasitism on several crop plants, H. L. LeClerc. (U. S. D. A. and Minn. Expt. Sta.). (*Phytopathology*, 29 (1939), No. 7, pp. 609-616, fig. 1).—The author compared damping-off tests and direct inoculation of underground stems of older plants as a basis for determining physiologic races of *R. solani*. "The results for individual isolates from the damping-off data in successive tests were more variable than were those from direct inoculations. The latter method appears most promising, if a large number of plants are inoculated with each isolate to be tested and if environmental conditions can be accurately controlled."

The Plant Disease Reporter, [June 1 and 15, 1939] (U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr., 23 (1939), Nos. 10, pp. 159-180; 11, pp. 181-202, figs. 3).—The following are included:

No. 10.—Diseases of fruits and vegetables on the New York market during the months of January, February, and March, 1939, by C. O. Bratley and J. S. Wiant; the Utah tomato disease situation [early top, *Verticillium* wilt, and bacterial canker] in 1938, by H. L. Blood and R. M. Christiansen; spindle sprout in potatoes on Long Island, by F. M. Blodgett; reports on vegetable diseases in New York, including onion smut and downy mildew in the muck crop areas, and truck crop diseases on Long Island; flax rust in Texas, by G. E. Allstott; diseases of cereals in Georgia, by J. H. Miller; observations on small grain diseases in Virginia, May 9 to 15, 1939, by S. B. Fenne; other reports on diseases of cereals, including rusts in Texas, condition of winter wheat in Kansas, and the first report of the year of wheat leaf rust in Nebraska; tobacco downy mildew appears in Massachusetts, by O. C. Boyd; downy mildew and other tobacco diseases in Kentucky, by E. M. Johnson; downy mildew on tobacco in Ohio, by C. C. Allison; tobacco diseases in Georgia, by H. I. Borders; bacterial ring spot of potato in Wyoming, by G. Hartman; and plant diseases in southern California, by H. G. MacMillan and O. A. Plunkett.

No. 11.—A tabulation of elm specimens cultured and percentages yielding *Ceratostomella ulmi*, 1930 to 1938, by E. G. Kelsheimer, L. M. Fenner, C. E. Dike, and C. May; observations on the death of peach trees (probably due to a combination of summer drought followed by rain in the late fall and subsequent marked temperature fluctuations) in the Nashville, Ark., peach district in 1939, by J. C. Dimegan; reports on the development of apple scab in Rhode Island, New York, Delaware, Illinois, northwest Arkansas, and Wisconsin; reports on fire blight from New York, Ohio, Illinois, and Wisconsin; notes on the cedar rusts from Massachusetts, New York, Illinois, and Wisconsin; reports on peach diseases, including leaf curl and *Phoma* disease in Delaware, and leaf curl and bacterial spot in Illinois; reports on diseases of cherry, including bacterial gummosis on sweet cherry trees in New York, cherry leaf spot in New York, and leaf spot in Wisconsin; other reports on fruit diseases, including black rot leaf spot on apple in Delaware, red core disease of strawberry in Delaware, and orange rust on wild blackberries in Illinois; some reports on diseases of tobacco (in Kentucky blue mold in old plant beds, a destructive epidemic of bacterial leaf spots in Kentucky, and sun scald or sun burn on tobacco in North Carolina); cottonseed treatment effective in Arkansas this year, by V. H. Young; pasmo disease of flax in the Lower Rio Grande Valley of Texas, by G. H. Godfrey and H. Rich; observations on flax diseases in Texas, by A. C. Dillman; cereal diseases in New York, by K. D. Butler; brief notes on cereal diseases, including leaf rust on wheat in Kentucky, and wheat diseases in Oklahoma and Kansas; bacterial ring rot of potatoes in Kern County, Calif., by P. A. Ark and M. W. Bodine; plant diseases in southern California, by

H. G. MacMillan and O. A. Plunkett; and brief notes on potato blackleg in Kentucky.

Reports on research for 1938: Plant pathology, G. M. Rurn (*Brooklyn Bot. Gard. Rec.*, 28 (1939), No. 2, pp. 47-51).—Reports of progress are included on studies of the inheritance of resistance in oat hybrids to loose and covered smuts, physiologic races of oat smuts, experimentally produced physiologic races of oat smuts, and sorghum smut investigations.

[Abstracts of papers on plant diseases presented at University of Colorado, 1937] (*Jour. Colo.-Wyo. Acad. Sci.*, 2 (1938), No. 4, pp. 25, 26).—Abstracts of the following are included: Invasion of Onion Roots by *Phoma terrestris* Hansen, and Vascular Rhizoctonosis of Sugar Beets, both by W. A. Kreutzer (Colo. State Col.).

[Abstracts of papers presented at Colorado State College of Education, 1938] (*Jour. Colo.-Wyo. Acad. Sci.*, 2 (1939), No. 5, pp. 32, 33, 34, 39).—Abstracts of the following papers of interest to phytopathology are included: The Resistance of Potato Dry-Rot Fusaria to Cold Temperatures, and Treating Cottonwoods for Chlorosis, both by G. H. Starr (Wyo. Expt. Sta.); and Further Studies on the Pink-Root Disease of Onions, by W. A. Kreutzer, and The Effects of HCN Gas, Methyl Bromide, and Methyl Bromide and Carbon Dioxide on Tomato Fruits and Greenhouse Plants, by C. R. Jones (both Colo. State Col.).

Kansas mycological notes, 1937, C. O. JOHNSTON and T. E. BROOKS. (U. S. D. A. and Kans. State Col.). (*Kans. Acad. Sci. Trans.*, 41 (1938), pp. 121-123).—Seasonal field notes, with particular reference to cereal rusts, tree diseases, and fungi new to Kansas, of which a list of 14 is given.

[Phytopathology at the New Haven Station] (*Connecticut [New Haven] Sta. Bul.* 421 (1939), pp. 20-23, 35-37, 45, 46).—Brief reports are included on work with copper sprays on muskmelons, cucumbers, tomatoes, carrots, and beets; "X disease" of peach studies, including control by destroying neighboring chokecherries; apple sprays; chestnut blight; elm and maple diseases; nematode control of chrysanthemums; control of white pine blister rust and of Dutch elm disease; and tobacco diseases at the Tobacco Substation, including downy mildew.

[Plant disease studies by the Kentucky Station] (*Kentucky Sta. Rpt.* 1938, pt. 1, pp. 18, 21, 21-25).—Observations and progress of work on the following are included: Phony peach disease (coop. U. S. D. A.); the effect of boron on the growth of plants; mosaic-resistant tobacco; a new tobacco plant-bred disease (apparently due to high salt content of soil surface); Bordeaux treatment of tobacco seedbeds; inoculation and longevity studies with *Bacterium tabacum* (= *Phytophthora tabaci*) and *B. angulatum* (= *P. angulata*); *Fusarium* yellows of tobacco; mosaic-free "barn-cured" chewing tobacco; and water-soaking injury to tobacco leaves, and the relation of stomata to water soaking.

[Plant disease work by the Massachusetts Station] (*Massachusetts Sta. Bul.* 355 (1939), pp. 15-17, 20-22, 29-33, 35, 36, 43, 44, 45).—Reports of progress are included on the following: Onion blast disease, by W. G. Colby; tobacco disease studies, including black root rot, and reductions in yield and quality due to mosaic, both by C. V. Kightlinger (both coop. U. S. D. A.); diseases of ornamental herbaceous plants due to soil-infesting organisms, with particular attention to control, and damping-off and growth of seedlings and cuttings of woody plants as affected by soil treatments and environal modifications, both by W. L. Doran; chemical soil surface treatments in hotbeds for controlling damping-off of early forcing vegetables, by Doran and E. F. Guba; apple scab control, and sprays for cucumber, muskmelon, and tomato, both by Guba and

C. J. Gilgut; control of greenhouse vegetable diseases, by Guba; diseases of trees in Massachusetts, by M. A. McKenzie and A. V. Osmun; studies of some physical and chemical properties of mosaic viruses, by M. E. Freeman; development of cranberry strains resistant to false blossom, spraying experiments for control of rosebloom, and spraying experiments for cranberry fruit rot control, all by H. F. Bergman and W. E. Truran; and blueberry disease studies, by Bergman.

[Plant pathology at the Puerto Rico College Station] (*Puerto Rico Col. Sta. Rpt. 1938*, pp. 44-46, 48-54, 61, 62, 75, 76).—Brief progress reports concern the following: The development of new eggplant varieties resistant to bacterial wilt, and new cucumber varieties resistant to downy mildew, both by A. Roque and J. Adsuar; diseases of bananas and plantains, particularly twisted top, bunchy top, black tip, and *Glomosporium* fruit rot, by A. R. López; *Cercospora* leaf spot of bananas, by M. T. Cook; coffee root rots, particularly *Roseellinia bunodes* and *Fusaria*, by L. A. Alvarez and Cook; disease survey of coffee farms, *Colletotrichum* dieback of coffee, and "mal de guaba" disease of *Inga inga*, all by Alvarez; pineapple diseases (particularly wilt), sugarcane diseases, and diseases of yams (with special reference to fungus isolations), all by López; soil alkalinity as an indirect cause of a serious chlorosis in coffee trees, by J. Guisasafré Arrillaga and L. A. Gómez; and variety-resistance tests against mosaic of sugarcane, by P. Richardson Kuntz.

[Phytopathology at the Wisconsin Station]. (Partly coop. U. S. D. A.). (*Wisconsin Sta. Bul. 443* (1939), pp. 6, 7, 8, 14-33, figs. 9).—Brief accounts are included of a new laboratory procedure for separating and identifying plant viruses by chemicals, by W. B. Allington and J. Johnson; the development of scab-resistant potato breeding stock, by G. H. Rieman, R. H. Larson, and J. C. Walker; the behavior of early blight (*Macrosporium solani*) on tomato, development of better disease-resistant tomato varieties for the State, and tomato spraying tests, all by O. C. Whipple and Walker; fertilizer in the control of root rot of canning peas, by Walker and F. L. Mushach; the practicability of seed treatment for canning peas in Wisconsin, by Walker and E. J. Delwiche; development of resistance to necrotic wilt in peas by breeding, and early mosaic-resistant canning beans producing best yields, both by Walker; borax in the prevention of diseases of garden beets, sugar beets, and cabbage, by Walker, J. P. Jolivet, and J. G. McLean; some commercial cabbage seed susceptible to yellows, by Walker; factors affecting yellow dwarf of potatoes, by R. H. Larson and Walker; spread of potato virus diseases by various insects, by Walker and Larson; variations in the degree of scab resistance in potatoes with conditions, by Walker, Larson, and A. R. Albert; straw as an aid in preventing "sprain" in potatoes, by Larson, Walker, and Albert; spraying of potatoes proved advantageous in both wet and dry years, by Whipple and T. C. Allen; modified bordeaux spray promising for cherry leaf spot control, by G. W. Keitt and C. N. Clayton; and studies of forest tree diseases, including dying of oak trees, by A. J. Riker and C. A. Richards, white pine blister rust, by Riker and T. F. Kouba, and damping-off in forest nurseries, by Riker and L. F. Roth.

[Plant disease work by the Wyoming Station] (*Wyoming Sta. Rpt. 1938*, pp. 5, 6, 7).—Brief reports are included on studies of cottonwood chlorosis treatment by ferric phosphate, bacterial bean blight, dry rot of potato, pea seed treatment, and selection and breeding of alfalfa for resistance to bacterial wilt.

Insoluble copper fungicides, A. A. NIKITIN (*Tenn. State Hort. Soc. Proc.*, 34 (1938), pp. 94-97, pls. 5).—The development and use of modern insoluble copper fungicides are reviewed, with 15 bibliographic footnotes.

Root development in relation to root rots of cereals, P. M. SIMMONDS (*Sci. Agr.*, 19 (1939), No. 7, pp. 475-480).—From interpretations based largely on studies of take-all, browning root rot (*Pythium* associated), and common root rot (*Helminthosporium sativum* and *Fusarium* spp.) in Saskatchewan, the prime importance of the state of health of cereal seeds is pointed out. In the seedling stage, especially in wheat, the plants are supported entirely by the seminal roots. Root infections during this period are shown to be responsible for much injury, usually accompanied by distinct shoot symptoms. Infections of the crown, crown roots, and tiller buds are considered in relation to post-seedling invasion, the damage here being particularly severe when the seminal roots also are infected. The seminal and crown roots are shown to play important roles in the growth of the plant, the former penetrating deeply and reaching the subsoil moisture early in the season and remaining functional as long as the plant lives, while the crown roots support any increase in growth when the tillers develop. Root rot infections are compared to artificial injuries to both root systems, the reactions being comparable in many respects. Observations are also made from physiological and pathological angles on the possibilities of developing a wheat plant supported entirely by the seminal roots. There are 17 references.

Coprinus urticaecola on stems of Marquis wheat, W. F. HANNA (*Mycologia*, 31 (1939), No. 3, pp. 250-257, figs. 2).—*C. urticaecola* was observed at Winnipeg on Marquis wheat (1934), the fruit bodies being attached near the ground to leaf sheaths of green plants. Later (1937) it was collected on decaying nettle stems. It is considered identical with *C. brasiliense* and with *C. phaeosporus* Karst. *sensu* Lange. The fungus grew readily on potato-dextrose agar and fruited on a number of sterile media. However, fruit bodies failed to develop when wheat plants in the greenhouse were inoculated with mycelial cultures. The fungus characters are discussed and illustrated.

Observations on stem rust of wheat in Mexico during the month of February 1938 [trans. title], E. C. STAKMAN, W. L. POPIAM, and R. C. CASELL (*Agricultura [México, D. F.]*, 2 (1939), No. 10, pp. 3-5).—Field observations in various parts of Mexico on *Puccinia graminis tritici* and identification of physiological races, including a list of those collected with localities.

Shrivelling of wheat kernels by stem rust and its effect on seed value, H. W. MEAD (*Sci. Agr.*, 19 (1939), No. 7, pp. 481-493, figs. 3).—The dry weights of embryos of kernels shriveled by stem rust proved to be 41.6, of fiber 57.1, and of endosperm 37 percent of those of normal kernels, indicating that the formation of endosperm tissue tends to be retarded by rust more than that of any other kernel tissue. Shriveled wheat germinated almost as well in the laboratory as normal wheat, but planted in soil it produced fewer and weaker seedlings, these weak plants emerging later, having smaller root systems, and being lighter in weight. The low vigor of seedlings from shriveled wheat was reflected in their poor resistance to common root rot, and greater permanent damage was done to them by severe top injury. However, these weak seedlings withstood freezing and prolonged drought as well as normal seedlings. Fungicide treatment of shriveled wheat caused serious reductions in germination and emergence, and appeared to make the seedlings very susceptible to common root rot. On the other hand, treatment with New Improved Ceresan or Leytosan proved very slightly beneficial. Despite the apparent weakness of plants from shriveled wheat, good stands and yields were obtained in field tests (1936), and the results here reported were corroborated by a provincial survey of areas where shriveled wheat had been sown.

Seed corn treatments, C. M. HAENSELER (*New Jersey Stas. Cir.* 384 (1939), pp. 3).—This is a discussion of the threefold action of and practical directions for fungicidal treatments of seed corn.

The relation of moisture and temperature to growth of the cotton root rot fungus, C. H. ROGERS. (Tex. Expt. Sta.). (*Jour. Agr. Res.* [U. S.], 58 (1939), No. 2, pp. 701-709, figs. 2).—*Phymatotrichum omnivorum* mycelial strands grew in Houston black clay soil under soil moistures of 15-35 percent (oven-dry basis), the optimum being ± 25 percent, or 35 percent of the maximum water-holding capacity. Sclerotia developed at soil moistures of 15-30 percent, but neither sclerotia nor mycelial strands grew at or below 8 percent or above 35 percent. Both developed in constant-temperature water baths at 11°-37° C., the optimum for each being $\pm 27^\circ$. At the lowest temperature used (3°) there was no active growth, but the fungus was apparently not injured. At 39° and above, the fungus died. At the lower temperatures both sclerotia and mycelia were whitish-amber in color, and at the minimum temperature for growth this color was retained throughout the experiment. At higher temperatures both sclerotia and mycelia were formed with the usual dark color of maturity in the field. Both strands and sclerotia were rapidly killed by high temperatures or drying, such as occur under ordinary summer conditions in the field. Moisture is said to be the limiting factor during the growing season, intermittent rains of sufficient quantities causing rapid spread of the fungus, with death of a large portion of the cotton plants by the end of the season.

Dusting Spanish peanuts with sulphur, N. C. WOODROOF and B. B. HIGGINS (*Georgia Sta. Cir.* 117 (1939), pp. 12, figs. 5).—In the tests here reported dusting with sulfur increased the yield of both peanuts and hay, controlled the spread of *Cercospora* leaf spots, prevented excessive shedding of leaves, and improved the quality of the hay. Three treatments with 325-mesh sulfur are recommended at 2-week intervals, beginning 60-65 days after planting, applying early in the morning or late in the afternoon, and using 45-55 lb. per acre for the season. Fertilizer top dressings as supplements to the dusting program are suggested.

Bacterial wilt and soft-rot of the potato, R. BOND. (Maine Expt. Sta.). (*Amer. Potato Jour.*, 16 (1939), No. 5, pp. 109-114, figs. 3).—This disease, found in Canada in 1931 and in Maine in 1932, has since been reported from Pennsylvania, Florida, and Wyoming, and according to Burkholder the Maine disease, at least, is due to *Phytomonas sepcdonica* (M. S. R., 80, p. 209). Since the malady presents a potentially serious problem, the author describes and illustrates the symptoms to aid in detecting it. Studies in Maine appear to indicate that it is not overwintered in the soil but rather in the seed tubers. Its increase may be very rapid in the field, and circumstantial evidence suggests soil water as the disseminating agency here. It is claimed on experimental data that the disease cannot be eliminated by tuber examination during seed cutting or by roguing and seed plat methods, but partial control has been secured by planting whole seed tubers, thus preventing spread in cutting and handling. The only practical control is use of disease-free seed, the effectiveness of which has been shown (1937-38). Obviously prompt and reliable diagnosis is a necessity, and the smear-staining method of Racicot et al. (M. S. R., 80, p. 500) is recommended.

Controlling common scab of the potato on Long Island by the addition of mercury compounds to the fertilizer mixture and the relation of soil reaction to the treatment, H. S. CUNNINGHAM and P. H. WESSLES (*New York State Sta. Bul.* 685 (1939), pp. 20).—On the basis of investigation

and statistical analysis of the effect of adding mercury compounds to the fertilizer mixture and of the relation of soil reaction to fertilizer-mercury combinations, it is concluded that under Long Island conditions 4 lb. of either yellow oxide of mercury or calomel to each ton of fertilizer mixture will reduce the amount of scab on soils at pH 5.5 or below. Larger amounts give no more effective control and may result in decreased tuber yields. The yellow oxide proved more effective than calomel.

Potato scab and its control, L. J. WHEELER. (Mich. State Col.). (*Ind. State Veg. Growers' Assoc.*, [Ann. Rpt.], 10 (1939), pp. 50-62).—A semipopular account summarizing data on relative varietal susceptibility and control tests by seed treatment, which have given poor results. The importance of clean seed and clean slightly acid soil is emphasized.

Varietal resistance of potatoes to the effects of eelworm infestation, D. ROBERTSON (*Scot. Jour. Agr.*, 22 (1939), No. 2, pp. 172-174).—In the experiment reported, evidence was obtained that the variety *Epicure* can produce a surprisingly high yield in soil heavily infested with cysts of *Heterodera schachtii*. Whether or not this result was due to the discovery of a strain resistant to the effects of nematode invasion, the matter is deemed worthy of further investigation.

Chlorotic streak, C. W. EDGERTON. (La. Expt. Sta.). (*Sugar Bul.*, 17 (1939), No. 14, pp. 1, 2).—This is a brief report on the present known distribution of this sugarcane disease in Louisiana, on the promising results of seed treatment tests (especially hot water), and on suggested important lines of study regarding spread, effect on cane, varietal resistance, and roguing.

Seed selection and roguing in the practical control of mosaic disease of sugarcane in Louisiana, M. L. SHAFER (*Louisiana Sta. Bul.* 308 (1939), pp. 8).—The results of experiments here reported appear to indicate that a combination of seed selection and roguing is practical for cane mosaic control. In these tests, the amount of spread in Co. 281 and Co. 290 varied with the amount of infection in the cane used for seed, while there was very little spread in C. P. 28-19, C. P. 29-116, and C. P. 29-320. The most roguing was required by Co. 281, the average percentages rogued for 2 yr. being 7.7 and 9.3, respectively. Less roguing was required for Co. 290, the averages being 4.1 and 3.7. The less susceptible varieties (C. P. 29-320, C. P. 28-19, and C. P. 29-116) required very little roguing to keep them mosaic-free. The 2 years' work indicated that cane with very little infection can be grown at a reasonable cost in practically any part of the cane belt by careful seed selection, proper isolation of seed plats, and thorough, adequately supervised roguing. To be effective the roguing should begin as early as possible in spring and continue until late summer.

Tobacco diseases in 1938, P. J. ANDERSON (*Connecticut [New Haven] Sta. Bul.* 422 (1939), pp. 26-42, figs. 9).—This is a seasonal survey of incidence, with salient points and control tests and suggestions, with reference to downy mildew, recurrence of wildfire, hollow stalk, root rots, malnutritional disorders, ammonia injury in the seedbeds, blackfire in the seedbeds, bed rot due to *Pythium aphanidermatum*, blackleg (a bacterial bed rot), control of damping-off and bed rot by vapors of benzol and paradichlorobenzene, and *Fusarium* leaf blotch (or scab).

The physical chemistry of tobacco mosaic virus protein, M. A. LAUFFER and W. M. STANLEY (*Chem. Rev.*, 24 (1939), No. 2, pp. 303-321, figs. 9).—This critical review (57 references) deals with the shape and size of the tobacco mosaic virus protein particles, including optical, ultracentrifugation, viscosity, diffusion, rotational diffusion coefficient, filtration, X-ray, and adsorption studies; and further physicochemical studies, including the absorption spectrum, surface spreading, electrophoretic behavior, and changes due to pH effects.

The amino acids of tobacco mosaic virus protein, A. F. ROSS and W. M. STANLEY (*Jour. Biol. Chem.*, 128 (1939), No. 3, pp. LXXXVI, LXXXVII).—An abstract.

Investigations and observations on the "necrotic virus" in relation to the fungus *Thielavia basicola* [trans. title], J. SZIRMAI (*Phytopathol. Ztschr.*, 12 (1939), No. 2, pp. 219-227, figs. 7).—The author reports an association of the necrotic virus of tobacco, the virus-containing cells, and the fungus *T. basicola*.

Soil studies on the causes of the brown root rot of tobacco, E. D. MATTHEWS, C. A. RENEGLE, and R. P. THOMAS. (Md. Expt. Sta.). (*Jour. Agr. Res.* [U. S.], 58 (1939), No. 9, pp. 673-684, figs. 2).—The authors studied the chemical and biological soil factors associated with the field occurrence of the disease, including the nitrate-N, water-soluble P, cellulose, and C content of the soils and the isolation of *Sclerotium bataticola* from affected roots and from the soil around them. From the results of this work, it was found that the fungus is readily destroyed by air-drying, that it decomposes cellulose, and that it grows better in neutral to alkaline media, characteristics apparently in accordance with the field conditions influencing the occurrence and severity of the disease. Finally, in inoculation tests under controlled greenhouse conditions, *S. bataticola* induced symptoms typical of brown root rot of tobacco.

Web-blight, a disease of beans caused by *Corticium microsclerotia*, (I. F. WEBER. (Fla. Expt. Sta.). (*Phytopathology*), 29 (1939), No. 7, pp. 559-575, figs. 7).—*Rhizoctonia microsclerotia* was discovered in Florida in 1932 causing a destructive disease of beans, epidemics in bean fields occurring at scattered locations in the State during the warm, rainy summer weather and at such times causing total losses in extensive plantings. The aerial parts of the host alone are attacked and killed. This disease, designated as "web-blight," has not previously been reported on beans in the United States. It causes brown spots on the leaves, rapidly killing them. The pods become spotted as in anthracnose and rapidly deteriorate. Petioles and peduncles are also attacked. The characteristic sclerotia on diseased plants are an important diagnostic symptom, and they may remain viable for at least a year, constituting the primary type of inoculum for the spread of the disease. In culture, optimum growth occurred at pH 6, with some at pH 3 and 9. The cardinal temperatures were 15°, 29°, and 33° C. It is extremely pathogenic on many vegetable plants under optimum conditions, and is shown to be capable of parasitizing a wide range of crop and wild plants, both annual and perennial. The basidiospore stage is described as *C. microsclerotia* n. comb.

Tests of new dust and liquid fungicides in 1938 for control of celery leaf blights, R. NELSON (*Michigan Sta. Quart. Bul.*, 21 (1939), No. 4, pp. 295-307).—Chlorocide-sulfur-talc dusts gave superior control of leaf blights in three plantings of celery at Comstock, having smoother flowing properties and covering the foliage better than any materials previously tested. Basicop-sulfur-talc and Bordow-sulfur-talc dusts were less satisfactory but about equal in effectiveness to copper sulfate-lime and copper sulfate-lime-talc combinations. Bordeaux 8-12-100 and 8-6-100 controlled leaf diseases without perceptible foliage injury more effectively than the copper fungicides of low solubility, all of which caused sufficient injury to reduce yields. Grasselli Copper A was effective but caused foliage injury which was reflected in lower yields than in the bordeaux plats. Hydrated lime or zinc sulfate failed to prevent foliage injury by Basicop sprays.

A *Pythium* root rot of cucurbits, M. GOTTLIEB and K. D. BUTLER. (Univ. Ariz.). (*Phytopathology*, 29 (1939), No. 7, pp. 624-628, fig. 1).—A watery root and fruit rot of watermelons, honeydew melons, gull muskmelons, and crook-neck squashes occurring spontaneously in Arizona proved to be due to *P. aphan-*

dermatum, also shown to be capable of inducing a rapid decay of many other fruits and vegetables. Root infections followed inoculations in both greenhouse and field, and the fungus was able to penetrate uninjured root and fruit tissues in practically all cases studied. Detailed data on the growth and reproduction of the fungus on various media are reported. The optimum for mycelial growth was 37° C. Sporangial production was meager and transient, being induced only with difficulty in various fluid media at pH 5.4. Oogonia and oospores were produced in great but varying abundance in both greenhouse and field and on various inoculated fruits and vegetables.

Host-parasite relationships in pink root of *Allium cepa* L.—I, The pigment of *Phoma terrestris*, W. A. KREUTZER. (Colo. State Col.). (*Phytopathology*, 29 (1939), No. 7, pp. 629-632).—In Colorado, onion roots invaded by the pink root pathogen *P. terrestris* did not always show the usually associated pink-red root coloration, but were occasionally yellow to yellow-brown. Cultural studies indicated that although temperature and nutrient variation had little to do with this phenomenon, increasing the H-ion concentration produced a color change, the hue induced being comparable to that observed in nature. In preliminary trials with diseased pink roots and agar mats on which the fungus was growing, a color shift occurred from red to red-purple shades at pH 8.5 to a yellow to yellow-brown at pH 4.5. By extracting the fungus pigment with 0.1 N HCl followed by 0.1 N NaOH, it was obtained in a soluble state. Using the pigment in solution, a more sensitive test was obtained, the color shift occurring at pH 7-7.86. The pigment was obtained from its alkaline solution by adding saturated Na₂SO₄ and was returned to its soluble state only by treatment with 0.1 N HCl followed by 0.1 N NaOH. Since the material apparently is hydrolyzed by emulsion, it appears that at least part of the molecule is of the nature of a β -glucoside.

White rust of spinach, J. S. WIAIT, S. S. IVANOFF, and J. A. STEVENSON. (U. S. D. A. and Tex. Expt. Sta.). (*Phytopathology*, 29 (1939), No. 7, pp. 616-623, figs. 2).—This rust was first noted in March 1937 on the New York market in shipments from the Winter Haven region of Texas, and was destructive throughout this area during 1937-38. Following detailed taxonomic comparisons, the pathogen is assigned to *Albugo occidentalis*. There are 25 literature references.

Fire blight and its control, E. M. HILDEBRAND (N. Y. State Col. Agr., Cornell Ext. Bul. 405 (1939), pp. 32, figs. 23).—This is a popular compendium of present information on this bacterial disease of pome fruit trees and its control.

Evaluating orchard spray materials: A progress report, C. M. PRACTI (Sci. Agr., 19 (1939), No. 7, pp. 434-434).—In this attempt to evaluate some phases of the spraying problem hitherto receiving but little attention, the data presented indicate that an increase in crop production (apples) may be correlated with increases in bud growth, twig growth, and ash content of the leaves, and that the differences in these factors may be due to the different fungicides applied. It is believed that the best criterion for determining the value of fungicides and insecticides is the weight of marketable and clean fruit. It is brought out that there should be an evaluation of spray materials in relation to tree growth, foliage development, and total crop production in addition to the protection to the fruit. There are 29 references.

Recent developments in fungicides for the control of peach and apple diseases, R. H. HURT. (Va. Expt. Sta.). (Pa. State Hort. Assoc. Proc., 80 (1939), pp. 13-17, 19, 20).—Recognizing the general conclusion that different growing conditions exist each year and that varieties of peaches and apples respond no 2 yr. alike to a standard spray schedule, the author discusses the spraying problems in the light of the latest experiences relative to the dormant

spray, spring and summer sprays, arsenical injury, sulfur fungicides, pre-harvest spray for brown rot, dusting on the grading equipment for peaches, and fungicides for apple disease control including those containing copper or sulfur.

Apple fungicide schedule for 1939, H. W. ANDERSON. (Univ. Ill.). (*Ill. State Hort. Soc. Trans.*, 72 (1938), pp. 376-385).—Current recommendations for the official fruit spray schedule are summarized.

Secondary diseases of the apple, H. W. ANDERSON. (Univ. Ill.). (*Ill. State Hort. Soc. Trans.*, 73 (1938), pp. 168-177).—This is a summary of data on diseases (bitter rot, rusts, sooty blotch, and frog-eye leaf spot) which at times must be considered in the spray schedule due to serious losses caused by them in some seasons. The spray schedule is designed more for the primary diseases and insects and certain modifications are necessary to avoid excessive spray injury, but such modifications sometimes result in unexpected lack of control of secondary diseases. In such cases it may be necessary to use less effective materials for the control of primary diseases and pests in order to care for the emergency.

Causes of premature defoliation of sour cherry, E. J. RASMUSSEN. (Mich. State Col.). (*Oreg. State Hort. Soc. Ann. Rpt.*, 30 (1938), pp. 131-135).—In this address the author points out some of the characteristics of the various types of injury found to cause defoliation in Michigan (viz, fertilizer treatment, drought injury, leaf spot and physiological yellow leaf, insect injury, and spray injury), with recommendations for their control.

Basicop as a cherry spray in 1938, C. W. ROBERTSON and D. CATION (*Michigan Sta. Quart. Bul.*, 21 (1939), No. 4, pp. 291-295, fig. 1).—Spray tests in 1938 are reported to have given results essentially similar to those of 1937 (*E. S. R.*, 79, p. 645). Liquid lime-sulfur (25-100) in the recommended 4-spray program failed to give adequate control of the *Coccomyces hiemalis* leaf spot in either year. The tendency to fruit dwarfing and foliage injury again indicates a 4-spray program for bordeaux mixture (6-8-100) to be unsatisfactory for cherries in Michigan. Cupro K gave good control but injured the leaves severely. Basicop (3-8-100, and 3-6-100) has given good control and but little perceptible injury, but without added lime or $ZnSO_4$ -lime it has been unsatisfactory because of foliage injury. At 1.5-100 Basicop failed to give adequate control of leaf spot. A 4-spray program of Basicop- $ZnSO_4$ -lime at 2-1-1.5-100 showed definite promise as a cherry spray, in limited experiments giving adequate control with no foliage injury.

Recent advances in our knowledge of bacterial spot of peach, H. W. ANDERSON. (Univ. Ill.). (*Ill. State Hort. Soc. Trans.*, 72 (1938), pp. 479-488).—It is concluded from this review of recent studies that at present there seems to be no effective method of controlling bacterial spot. Certain points in the life history of the organism (*Phytophthora pruni*) have been cleared up and additional lines of attack are being tried out, including breeding and selection for resistance.

Progress in peach mosaic control, 1937-1938, B. M. GADNIS. (U. S. D. A.). (*Calif. Dept. Agr. Spec. Pub.* 166 (1938), pp. 57, 58).—The high lights at the close of 1937 embraced the inspection of over 3,500,000 peach trees on over 44,000 properties, in 185 counties in 9 southwestern States, during which over 74,000 diseased trees were located on nearly 5,000 properties. The annual reduction in diseased trees in most areas was generally proportionate to the percentage of diseased trees promptly removed during the previous year. The 1938 program covering all known infected States is briefly discussed.

Brown rot of peaches in transit and storage, R. S. WILLISON (*Sci. Agr.*, 19 (1939), No. 7, pp. 452-474, figs. 6).—Long distance shipping tests with

Rochester and Elberta peaches indicated that while the riper grades were more susceptible to *Sclerotinia fructicola* rot than the green, its incidence in the riper fruits may be delayed long enough to permit marketing. The later harvested fruits of both varieties were somewhat more susceptible to rot than the first pickings of the season. A number of forms of wettable sulfur were tested and, in general, those sprays applicable immediately before harvesting gave more uniform results than those which had to be applied 2-3 weeks earlier. Sulfur dusting also proved satisfactory except when it rained before harvest. Wastage as bruises and to a lesser extent as rots was reduced by care in handling operations. The incidence of rot was usually much higher when peaches were cooled after a 24-hr. delay than when this was done shortly after picking. Where cars were iced only on departure there was little difference in the development of rot in treated v. untreated peaches. There are 27 references.

Progress of zinc sulphate sprays and zinc sulphate and boron combinations for little leaf control at The Dalles, Oregon. O. T. McWHORTER (*Oreg. State Hort. Soc. Ann. Rpt.*, 30 (1938), pp. 68-70).—A brief progress report on work with little leaf of stone fruits.

Rust on the California native Pruni. C. O. SMITH and L. C. COCHRAN. (*Calif. Citrus Expt. Sta.*). (*Phytopathology*, 29 (1939), No. 7, pp. 645, 646, fig. 1).—*Tranzschelia pruni-spinosae* developed spontaneously on the following native California species of *Prunus* in a mixed planting: *P. andersonii*, *P. subcordata*, *P. fasciculata*, and *P. fremontii*. *P. emarginata* was infected artificially, while *P. demissa* and *P. ilicifolia* were not infected. This is believed to be the first report of this rust on wild species of *Prunus* in California.

Some recent observations on the red stele disease. J. H. CLARK (*N. J. State Hort. Soc. News*, 20 (1939), No. 4, pp. 1131, 1132).—Seasonal field notes in New Jersey, relating to this strawberry disease.

Yellows resistant Blakemore strawberries. R. R. MOUMER (*Tenn. State Hort. Soc. Proc.*, 34 (1938), pp. 97-99).—The origin of this resistant variety is given.

Susceptibility of seedlings of Ribes punctatum, and Andine currant, to Cronartium ribicola. G. G. HAHN. (U. S. D. A. et al.). (*Phytopathology*, 29 (1939), No. 7, pp. 643, 644).—Little is known as to the susceptibility of South American species of *Ribes* to *C. ribicola*, and so far as known the susceptibility of *R. punctatum* is here reported for the first time. It is believed that this tender evergreen, dioecious species would prove useful as a source of inoculum for greenhouse studies of the fungus during late fall and winter, when North American and European species of *Ribes* have lost their leaves.

Studies on filbert blight and its control: Second report of progress. P. W. MILLER. (U. S. D. A. and Oreg. Expt. Sta.). (*Oreg. State Hort. Soc. Ann. Rpt.*, 30 (1938), pp. 166-171).—This bacterial disease (U. S. R., 77, p. 807), is said to have been very prevalent and destructive in the Pacific Northwest in 1938, causing losses of 5-35 percent of the trees in young orchards up to 3 yr. old and an estimated indirect loss of 10-25 percent of the nut crop in the older orchards. This severity was associated primarily with the preceding abnormally rainy fall and winter. Disease development in 1938 occurred during the spring, its peak being reached late in April, while by early summer its development was largely over. The incidence of bud and twig blight in bearing orchards was reduced to traces by three applications of bordeaux mixture (4-2-50) in late summer, late fall, and early spring. The most important single spray was apparently the one made in late summer, and the least important the one of early spring. The net results obtained seem to indicate that in average western Oregon seasons the incidence and severity of bud and twig

blight in bearing orchards can be reduced to a negligible amount by a late summer or early fall bordeaux (4-2-50) treatment before the first fall rains appear. However, if the critical infection period is abnormally rainy, as many as three applications may be necessary, viz, (1) in late summer or early fall before the first fall rains, (2) in late fall when the leaves are about half off, and (3) in early spring when the leaf buds are opening and the green leaf tips are showing.

A promising new copper spray for the control of walnut blight, P. W. MILLER. (U. S. D. A. and Oreg. Expt. Sta.). (*Oreg. State Hort. Soc. Ann. Rpt.*, 30 (1938), pp. 148-151).—The results of the studies described (1935-38) appear to indicate that copper oxalate (1.5-2-50) is more effective under Oregon conditions for controlling bacterial blight of walnut than bordeaux mixture (2-2-50). Unlike the latter it is noninjurious to walnut leaves.

Nematodes observed on diseased rhizomes of ginger from Peru, G. STEINER and J. R. CHRISTIE. (U. S. D. A.). (*Helminthol. Soc. Wash. Proc.*, 6 (1939), No. 1, pp. 26-29, fig. 1).—*Diploscapter coronatus*, *Neoccephalobus peruvensis* n. sp., and *Apelonchoides huniti*, found on diseased rhizomes of *Zingiber* sp., are here added to the nematode fauna of Peru.

Bacteriosis of tuberous begonia, P. A. ARK and C. M. TOMPKINS. (Univ. Calif.). (*Phytopathology*, 29 (1939), No. 7, pp. 633-637, figs. 2).—A leaf spot of *Begonia tubcrhybrida* in lathhouse nurseries in California under high humidity and relatively high temperature conditions is reported. When inoculated with pure cultures of the pathogen, 12 species and varieties of begonia proved susceptible. Air humidity and temperature control are recommended for minimizing the injury from this bacteriosis. The pathogen was diagnosed as *Phytonomonas begoniae* and compared to *P. flavoconatum*, with which it is considered identical. The former, and earlier, name is preferred.

Factors affecting iron chlorosis in gardenias, H. E. WHITE. (Mass. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 34 (1937), pp. 774-780, figs. 3).—When severe, iron (Fe) chlorosis is said to become a limiting factor in the growth of gardenias. Chlorotic foliage became green when treated with Fe compounds but failed to respond to other so-called minor elements. In soil, the corrective effect of Fe compounds was very slow and no response to other minor elements was noted. Fertilizers containing NaNO_3 or $\text{Ca(NO}_3)_2$ induced Fe chlorosis, organic or ammonia sources of N in fertilizers prevented it, and P and K had no influence on it. Sulfur in amounts as low as 0.5 lb. per 100 sq. ft. of bench area prevented Fe chlorosis, and the chlorotic-inducing effect of Na and Ca was inhibited by S. On experimental evidence, conditions other than soil acidity would appear to be contributing factors where this chlorosis is concerned. Supplementary illumination in winter failed to reduce the trouble. Growing gardenias at 50° F. resulted in a chlorosis not corrected by Fe applications and not responding to ammonia forms of N. Diseases such as nematodes and stem canker accentuated the Fe chlorosis symptoms.

Bulb nematode control in iris by hot water, R. J. HASTINGS, J. E. BOSHER, and W. NEWTON (*Canad. Jour. Res.*, 17 (1939), No. 5, Sect. C, pp. 144-146).—"The immersion of iris bulbs in water at 110° to 112° F. for 60 min. effectively destroys the bulb nematode. The safe period for nematode destruction in iris by hot water lies between July 26 and August 9. Thereafter injury to the bulbs occurs and is progressively greater as the immersion dates are delayed."

Two species of *Hysteriales* on smilax, E. K. CARR. (U. S. D. A.). (*Mycologia*, 31 (1939), No. 3, pp. 289-296, figs. 2).—*Hypodermopsis smilacis* n. comb. and *Montopsis ellisi* n. nom. are described, illustrated, and discussed. "The superficial resemblance of these two species and their growth on the same host has led to mixed collections, apothecia of both fungi being sometimes present

on the same stem, only a few centimeters apart. . . . An added source of confusion is the fact that some descriptions appear to combine characters of both fungi under a single name."

Studies on control of tulip blight, A. T. GUARD. (Purdue Univ.). (*Ind Acad. Sci. Proc.*, 53 (1937), p. 73).—An abstract.

Diseases of ornamental plants, P. P. PIRONE (*New Jersey Stat. Agr.* 385 (1939), pp. 80, figs. 65).—After brief introductory statements on the nature of parasitic agents and on plant disease control, this compendium, a revision of Circular 226 (E. S. R., 65, p. 352), takes up in turn the specific diseases of box, calla, carnation, China-aster, chrysanthemum, dahlia, delphinium, geranium, gladiolus, hollyhock, iris, ivy, laurel, lilac, lily, peony, phlox, rhododendron, rose, snapdragon, sweet pea, and tulip. Being more or less omnivorous in attack, damping-off of seedlings, winter injury of evergreens, mosaics, rusts, mildews, and nematodes are also discussed separately, with lists of plants commonly concerned. Fungicides and soil sterilization or pasteurization each have a brief section, and an index is provided.

Diseases of nursery plants, M. A. MCKENZIE. (Mass. Expt. Sta.). (*Amer. Nurseryman*, 68 (1938), No. 7, pp. 3, 4).—A brief summary of pertinent data on infectious and noninfectious diseases of evergreen and deciduous nursery trees in the open.

Spray trials on ornamental red cedars, F. C. STRONG and E. J. RASMUSSEN (*Michigan Sta. Quart. Bul.*, 21 (1939), No. 4, pp. 277-279).—In nurseries and ornamental plantings of *Juniperus virginiana* with hawthorns, flowering apples, and crab apples, the increasing importance of the rust diseases due to *Gymnosporangium* spp. is stressed. In such cases planting of the alternate hosts a mile or more distant is impractical, and many of the favorite landscape varieties are very susceptible. Since at least 12 mo. must elapse after infection before the cedar galls become visible it was impossible to determine the control effects of the preliminary spray trials with wettable sulfur here reported, and since the 1938 weather conditions were unfavorable for sulfur spray injury definite conclusions could not be drawn as to possible foliage injury by wettable sulfur. However, the soybean oil sticker used in some of the tests caused distinct foliage injury on two varieties. Other combinations with stickers (soybean flour and Orihex) and wettable sulfur alone gave no apparent injury.

Leafspot of ash and *Phyllosticta viridis*, F. A. WOLF (*Mycologia*, 31 (1939), No. 3, pp. 258-266, figs. 14).—The leaves of several *Fraxinus* species may be infected by a *Phyllosticta* commonly identified as *P. viridis*, a fungus widely distributed in the United States east of the Rocky Mountains. Leaf lesions form in late summer, and severe defoliation may result. The black stromata protruding from the lower leaf surfaces aid in diagnosis. At this stage they contain both spermatogonial and carpogonial locules, the former said to be identical with *P. viridis*. The carpogonial locules become transformed by early spring into mature perithecia, this stage being identified as *Mycospheraella fraxincola*. The ascospore discharge period extends into early summer, and infection is first apparent by the presence of stromata. Present evidence indicates there is no conidial stage.

Chestnut breeding work in 1938, A. H. GRAVES (*Brooklyn Bot. Gard. Rec.*, 28 (1939), No. 2, pp. 55-60, fig. 1).—This is a progress report on work directed toward the development of a new chestnut resistant to *Endothia parasitica* to replace the now nearly extinct American chestnut. Cooperative assistance and plantings, a summary of new hybrids, and a list of chestnut species, varieties, and hybrids growing at Hamden, Conn., October 1938 are given.

Studies on *Polyporus abietinus*.—III, The influence of certain factors on the rate of decay of loblolly pine sapwood, K. H. GARREN (*Jour. Forest.*

try, 37 (1939), No. 4, pp. 319-323, fig. 1).—In further studies (E. S. R., 80, p. 507) a statistical analysis of the results of decay in *Pinus taeda* sapwood showed that both specific gravity and moisture content are significant in determining the rate, the indications being that the higher the specific gravity the greater will be the resistance to sapwood decay by this fungus.

White pine blister rust in Wisconsin, E. L. CHAMBERS and T. F. KOUBA. (U. S. D. A.). (Wis. Dept. Agr. and Markets Bul. 204 (1939), pp. 35-48, figs. 7).—This is a bulletin of information on the value of white pine in Wisconsin, the distribution and present status of blister rust in the State, and other pertinent data on the recognition and control of this disease.

Principal decays of softwoods used in Great Britain, K. St. G. CARTWRIGHT and W. P. K. FINDLAY (London: Dept. Sci. and Indus. Res., 1938, pp. 106, pls. [17], figs. [4]).—This is the second in a series of publications (E. S. R., 78, p. 213) dealing with the fungi causing decay in the principal commercial timbers. While the diseases of home-grown conifers are here dealt with in greater detail, the principal types of rot and "dote" commonly found in softwoods imported from northern Europe and America are also described. The economic importance of the different types of decay are indicated, but the silvicultural aspects of the rots of standing conifers are referred to only briefly.

Attractiveness of roots and excised shoot tissues to certain nematodes, M. B. LINFORD. (Hawaii. Pineapple Producers' Expt. Sta.). (Helminthol. Soc. Wash. Proc., 6 (1939), No. 1, pp. 11-18, figs. 2).—Microscopic observations indicated that *Heterodera marioni* larvae congregate around roots and move down to the elongating zone just behind the root cap. Larvae and females of *Pratylenchus pratensis* and *Rotylenchus multicaudatus* congregated more slowly around the roots and remained in the mature root zone, where they penetrated and fed. *Aphelenchus avenae*, reared in agar-fungus cultures, exhibited but little grouping around the roots. Pieces of fresh tissue cut from green leaves and stems of diverse plants proved strongly attractive to *H. marioni* larvae and remained attractive as they decomposed. More limited tests indicated that *R. multicaudatus* likewise responds to green tissues but that *A. avenae* does not. *H. marioni* larvae in agar congregated around yeast colonies over which glass cover slips had been placed, indicating either an attraction or a trapping by the mechanism of retarded locomotion through anaerobiosis.

ECONOMIC ZOOLOGY—ENTOMOLOGY

Wildlife Review, [January-May 1939] (U. S. Dept. Agr., Bur. Biol. Survey, Wildlife Rev. Nos. 18 (1939), pp. 33; 19, pp. 36; 20, pp. 36; 21, pp. 32).—A continuation of this series (E. S. R., 80, p. 650).

Wildfowl food plants: Their value, propagation, and management, W. L. MCATEE (Ames, Iowa: Collegiate Press, Inc., 1939, pp. IX+141, figs. [21]).—The chapters of this work deal, respectively, with productivity, value, and utilization of wildfowl food plants; wild-duck food plants by families; environmental limitations on the growth of aquatic plants; planting suggestions; construction of ponds; control of undesirable plants and animals; and vernacular names of wildfowl food plants. A list of 37 references to the literature and an index are included.

Wildlife mortality on Iowa highways, T. G. SCOTT. (Iowa Expt. Sta., coop. U. S. D. A. et al.). (Amer. Midland Nat., 20 (1938), No. 3, pp. 527-539).—Observations of wildlife casualties on Iowa highways conducted from May 1936 to April 1937, inclusive, covering a rural distance of 2,944.1 miles distributed over 43 counties, are recorded, the details being given in 5 tables.

American bird biographies.—[II], *The golden plover and other birds*, A. A. ALLEN (*Ithaca, N. Y.: Comstock Pub. Co., 1939, pp. XIII+324, pls. 7, [figs. 242]*).—This second series of biographies (*E. S. R., 77, p. 212*) considers the life and habits of 27 additional forms. Seven colored plates by G. M. Sutton and 242 photographs of birds in nature by the author are included.

Food of game ducks in the United States and Canada, A. C. MARTIN and F. M. UHLER (*U. S. Dept. Agr., Tech. Bul. 634 (1939), pp. 157, pls. 153, figs. 137*).—In this work the available information on waterfowl foods, including much recently gathered in field investigations, have been brought together by the authors. Part 1 (pp. 3–18) presents regional data on duck foods. Part 2 (pp. 19–101) considers the principal duck foods—their identification, value, and range. Part 3 (pp. 103–142) gives the propagation of waterfowl food plants and development of feeding grounds. Part 1 includes tables of data on the principal foods in eight regions of the United States and Canada. Within each region the figures on food use have been based on locality units, 247 in all, graded according to their representation by duck stomachs. Part 2 treats descriptively more than 200 food items in systematic order. The 123 test maps indicate the general known range of the plants and in many instances depict areas of greatest abundance, isolated occurrence, and districts of uncertain distribution. Part 3 presents practical suggestions on harvesting, storage, germination, shipment, and planting, and treats in some detail the principal factors, favorable and otherwise, influencing growth. A list is given of 91 references to the literature cited, and an index is included.

Food habits of North American diving ducks, C. COTTAM (*U. S. Dept. Agr., Tech. Bul. 643 (1939), pp. 140, pls. 10, figs. 5*).—This bulletin treats of the food habits of the 22 North American diving ducks (exclusive of mergansers), which may be roughly segregated as inland divers and sea ducks. It is based both on field studies and on the analyses in the Food Habits Laboratory of the Bureau of Biological Survey of the stomach contents (including both gizzard and gullet) of 6,665 adults and 141 juveniles. For each species there is a summary of distribution, habits, and status, along with detailed data on food preferences.

The inland divers include the redhead, ringneck, canvasback, greater and lesser scaups, ruddy duck, and the masked duck. With the exception of the greater scaup, which consumes nearly equal proportions of plant and animal food, all are predominantly vegetarians, feeding on tubers, underground rootstalks, seeds, and green vegetative fibers of many aquatic and marsh plants. The sea ducks include the American and Barrow's goldeneyes, bufflehead, oldsquaw, and harlequin duck; the eiders—Steller's northern, American, Pacific, king, and spectacled—and the scoters—White-winged, surf, and American. All of these are predominantly animal feeders. For the inland divers, relatively few plants appear to be of outstanding value as food, but most important are the submerged pondweeds (*Najas*), wildcelery (*Vallisneria spiralis*), muskgrass (*Characeae*), watershield (*Brasenia schreberi*), wildrice (*Zizania aquatica*), bulrushes (*Scirpus*), and smartweeds (*Polygonum*). The most important animal foods are mollusks and insects, particularly caddisfly and midge larvae, water bugs, and water beetles. A section of the bulletin treats of methods of propagating desirable duck foods. For the sea ducks, mollusks (mostly pelecypods, especially *Mytilus edulis*) were the most important food for eight species, crustaceans for four, and insects for two. Fishes are acceptable to all the species treated but were consumed in small numbers, and the kinds taken are rarely of commercial or sporting importance. It is concluded that, within limits, availability is the most important factor governing food selection. When an acceptable food is found the adults often

make their entire meal on a single or a related group of species. The young of most species fed principally upon animal foods, mainly insects, crustaceans, and small mollusks, although some juveniles showed a decided, even though indiscriminate, preference for vegetable material.

A list is given of 97 references to the literature cited.

North Dakota hawks: Their value to agriculture, S. SAUGSTAD (*North Dakota Sta. Bino. Bul.*, 1 (1939), No. 5, pp. 14-19, figs. 2).—This discussion of hawks of the State, in which the relative value of the species to agriculture is pointed out, includes a key for identification by wingspread dimensions and other marked characteristics.

The fall foods of ringneck pheasants and bobwhites, L. J. BENNETT and P. F. ENGLISH. (Pa. Expt. Sta., U. S. D. A., et al.). (*Pa. Game News*, 10 (1939), No. 1, pp. 8, 9, 29, figs. 3).—In this first report of cooperative work on fall foods, 74 percent of the volume of food in the crops of 423 pheasants consisted of crop seeds (corn and attendant weed seeds, including ragweed and foxtail), as did 81 percent of the volume of food in the crops of 61 bobwhites. "Sixteen percent of the pheasant food and 11 percent of the bobwhite food consisted of noncrop seeds and fruits from grape, dogwood, sourdock, and other plants. Animal matter, consisting mostly of grasshoppers, constituted 6 percent of the pheasant food and 5 percent of the bobwhite food. The volume of noncrop seeds and animal matter found in the crops of both pheasants and bobwhites was small. These foods, however, probably aid greatly in providing a balanced diet."

[Notes on economic insects and their control] (*Jour. Econ. Ent.*, 52 (1939), No. 2, pp. 342-347, figs. 5).—The contributions presented (E. S. R., 81, p. 237) are: *Micromyzus oliveri* Essig as a Greenhouse Pest, by C. F. Doucette (pp. 342, 343) (U. S. D. A.); Dryer and Protector for Insects, by A. R. Shadle (pp. 343, 344); Derris of High Rotenone Content, by H. A. Jones (p. 344) (U. S. D. A.); Methyl Bromide Injury to Apples, by W. R. Phillips and H. A. U. Monro (pp. 344, 345); Two Unusual Species of Aphids [*Rhopalosiphum splendens* (Theob.) and the Apple Grain Aphid] Infesting Wheat, by M. A. Palmer (pp. 345, 346) (Colo. Expt. Sta.); and Natural Foods of *Cochliomyia americana*, the True Screwworm, by A. L. Brody (pp. 346, 347) (U. S. D. A.)

[Contributions on economic insects and insect control] (*Phytopathology*, 29 (1939), No. 1, pp. 9, 10, 12, 13).—Among the contributions presented at the annual meeting of the American Phytopathological Society in Richmond, Va., in December 1938 are the following: Cultural Studies on a Species of *Entomophthora* From the Apple Leaf Hopper *Typhlocyba pomaria*, by J. G. Harrar, L. I. Miller, and S. A. Wingard (p. 9); Red Leaf Disease of Grapes in California Cured by Controlling Mites [*Tetranychus pacificus*], by W. B. Howitt, H. E. Jacob, E. L. Proebsting, and J. F. Lamiman (p. 10); and The Relation of Copper Fungicides to Lead Arsenate-Lime and Fixed Nicotine-Oil Sprays, by K. J. Kadow, M. W. Goodwin, and S. L. Hopperstead (pp. 12, 13).

[Contributions on economic insects] (*Rev. Pathol. Vég. et Ent. Agr. France*, 25 (1938), No. 2, pp. 85-93, 111-118, 144-155, 163-176, figs. 9).—Contributions presented include the following: Use of Trap Bands in Control of the Codling Moth (*Laspeyresia pomonella* L.), by G. Viennot-Bourgin (pp. 85-93); Biology of *Bracon intercessor* Nees, Parasite of *Lixus* Rhinides of the Sugar Beet in Morocco, by P. Bremond (pp. 111-118); The Coccids of Madeira—I, Diaspididae: Asterolecaniinae, by A. Balachowsky (pp. 144-155); Investigations of the Life Cycle of the Mealy Plum Aphid (*Hyalopterus arundinis* F.) on the Swiss Plateau, by W. Dill (résumé by R. Clausen) (pp. 163-172); and Control of the Cherry Maggot *Rhagoletis cerasi* in Gironde, by J. Bruneau (pp. 173-176).

[Report of work in entomology by the New Haven Station]. (Partly coop. U. S. D. A.). (*Connecticut [New Haven] Sta. Bul. 421 (1939), pp. 24-33, 45*).—The work of the year reported upon (E. S. R., 79, p. 359) relates to termite control (E. S. R., 79, p. 358), the oriental fruit moth, European red mite, adhesives for standard spray mixtures, oil sprays for control of the rosy apple aphid, substitutes for lead arsenate in orchard sprays, the pales weevil, the European pine shoot moth, onion thrips, European corn borer, squash bug, potato flea beetle, corn earworm, Japanese beetle (E. S. R., 79, p. 514), and, at the Tobacco Substation, control of the potato flea beetle, wireworms, and tobacco thrips on tobacco.

Report on the insect investigations for the 1938 season, A. W. MORELL, Jr., and D. S. LACROIX. (Coop. U. S. D. A.). (*Connecticut [New Haven] Sta. Bul. 422 (1939), pp. 42-49, figs. 6*).—In reporting further progress (E. S. R., 79, p. 361), reference is made to experimental control work with the potato flea beetle and the tobacco thrips on shade tobacco, the potato flea beetle on sun-grown tobacco, flea beetle movement between tobacco and potato fields, the use of finely ground naphthalene and dichlorethyl ether in the control of the eastern field wireworm, insect losses sustained in sun-grown tobacco, and notes on the occurrence of tobacco insects, including the seed-corn maggot, the lesser migratory grasshopper (*Melanoplus mexicanus mexicanus* Sauss.), tobacco budworm, tarnished plant bug, tomato worm, tobacco worm, garden springtail, the spined stink bug (*Euschistus variolarius* Beauv.), dark-sided cutworm, and the spotted cutworm.

[Report of work in entomology by the Kentucky Station]. (Partly coop. U. S. D. A.). (*Kentucky Sta. Rpt. 1938, pt. 1, pp. 13-18*).—The work of the year reported (E. S. R., 79, p. 503) includes a May beetle survey; control of May beetle grubs; white grubs (*Phyllophaga ephialda*, *P. micans*, *P. crenulata*, *P. pruinosa*, *P. inversa*, *P. futilis*, and *P. hornii*) identified as strawberry pests; biology and control of the strawberry crown borer; the tomato fruitworm; oil-nicotine spray for control of plant lice on garden peas and roses and for tingids, in the field; nicotine for control of poultry lice (the chicken body louse, the shaft louse *Menopon gallinae* (L.), the fluff louse, the large chicken louse, the wing louse *Lipeurus caponis* (L.), and the chicken head louse); studies of orchard insects, particularly the codling moth and the plum curculio; June beetle larvae in tobacco plant beds; sod webworm control; experiments with eight different strains of clover for resistance to pea aphid injury; tobacco wireworms; clipping for control of the corn earworm and other corn earworm studies; oriental fruit moth parasites; and trapping for the Japanese beetle.

[Work in entomology by the Massachusetts Station] (*Massachusetts Sta. Bul. 355 (1939), pp. 38-41, 53-65, pls. 3*).—The work of the year briefly reported (E. S. R., 79, p. 503) includes insects affecting the cranberry (the fire beetle *Cryptocephalus incertus* Oliv., the cranberry weevil, the Atlantic cutworm *Polia atlantica* Grote, and the cranberry fruitworm), by H. J. Franklin; oil sprays for dormant applications for control of the European red mite, substitutes for lime-sulfur in summer sprays for orchards, and apple maggot control, all by A. I. Bourne and W. D. Whitcomb; control of the white apple leafhopper, plum curculio, cabbage maggot on cabbages and radishes, striped cucumber beetle on cucumbers and melons, the squash vine borer, biology and control of the apple leaf-curling midge, and naphthalene and similar compounds as greenhouse fumigants, all by Whitcomb; the spray residue problem, introduction of parasites (*Macrocentrus ancylivorus*) of the oriental fruit moth in peach orchards, potato spraying experiments, control of onion thrips, and insecticides for the control of the European corn borer, all by Bourne; insects (the native elm bark beetle and the smaller European elm bark beetle) concerned in the dispersal

of Dutch elm disease, by W. B. Becker; and control of the red spider on greenhouse plants, by Whitcomb and W. Garland.

[Work in entomology by the Puerto Rico College Station] (*Puerto Rico Col. Sta. Rpt. 1938, pp. 33-44*).—The work of the year reported (E. S. R., 79, p. 650) includes the maintenance of a supply of the vedalia, predator of the cottony-cushion scale, by G. N. Wolcott and F. Señ, Jr.; a study of the drywood termite, or "polilla," *Cryptotermes brevis* Walk., control of the papaya scale by pressure spraying with water, control of *Siphia flava* Forbes (the yellow aphid of sugarcane), and an effective poison bait for the control of the hormiguilla *Myrmelachista ramulorum* Wheeler in coffee groves, all by Wolcott; effectiveness of various commercial miscible oils and other oil sprays in the control of the West Indian peach scale and the gray scale *Pseudoparlatoria ostreata* Ohll. on papaya trees, the control of the sugarcane borer by the egg parasite (*Trichogramma minutum* Riley), establishment of *Larra americana* Sauss. (a parasite of the changa in Puerto Rico), and forest tree insects, all by Wolcott and L. F. Martorell; and a study of the coffee leaf-miner *Leucoptera coffecella* Guer. and humidity as a factor in leaf-miner infestations, both by Señ.

[Report of work in entomology by the Wisconsin Station]. (Partly coop. U. S. D. A.). (*Wisconsin Sta. Bul. 443 (1939), pp. 34-43, 44-50, figs. 4*).—The work of the year reported (E. S. R., 79, p. 651) relates to codling moth sprays and factors influencing their use, such as proper timing, consistent and thorough application, and effect of road dust on areas sprayed, by J. A. Callenbach; importance of following spraying recommendations for codling moth control, promising modified oil sprays for leaf roller control, new information on grasshopper baits at Sturgeon Bay, and control methods for the strawberry leaf roller, all by J. H. Lilly; control of grasshoppers by the use of sawdust baits, by H. F. Wilson; control of cutworms by the use of baits, by L. D. Beadle and Wilson; white grub and June beetle infestations and control of June beetles by insecticides, by T. R. Chamberlin, L. Seaton, C. L. Fluke, and Callenbach; effect of atomized oil sprays on truck crops, by T. C. Allen and T. L. Carpenter; control of cabbageworms and cucumber beetles by rotenones, and alkaline carriers injurious to rotenone, both by Allen and J. W. Brooks; yields of canning peas in 1938 increased by the use of insecticides, by J. E. Dudley, Jr., and T. E. Bronson; studies to determine when pea aphid insecticides should be applied, by E. M. Searls and G. S. Hales; and factors affecting the control of the pea aphid by the use of rotenone dust, including influence of moisture, effect of temperature, amount of rotenone and type of machine used, and condition of the peas, by Wilson and C. E. Dieter.

Annual reports of the entomologist for the years 1935 and 1936, W. H. EDWARDS (*Jamaica Dept. Sci. and Agr., Ann. Rpts., 1935, pp. 76-80, fig. 1; 1936, pp. 57, 58*).—The occurrence of and control work with the more important insects of the two years are reported in continuation of earlier reports (E. S. R., 75, p. 806).

Insects of Brazil, A. DE COSTA LIMA (*Insetos do Brasil. Rio de Janeiro: Escola Nac. Agron., 1939, vol. 1, pp. X+470, figs. 218*).—In this, the first part of a work on the insects of Brazil, 19 of 30 orders are considered in as many chapters, each of which includes a bibliography of the more important literature.

[Government of Northern Rhodesia, Veterinary Department, annual reports for the years 1935 and 1936] (*North. Rhodesia Vet. Dept. Ann. Rpts., 1935, pp. 35; 1936, pp. 76*).—Accounts of the occurrence of and control work with infectious diseases of livestock by J. P. A. Morris and H. S. Purchase are included in the 1935 report (E. S. R., 75, p. 104), and by J. P. A. Morris and P. L. le Roux in the 1936 report.

[Entomological work in the Sudan], H. W. BEDFORD (*Sudan Govt., Agr. Res. Serv. Ann. Rpt., 1936, pp. 38-52*).—This report relates particularly to a general survey of insect pests of crops in the Sudan and experimental work with cotton pests.

The development of applied entomology in Queensland, R. VETICH (*Roy. Soc. Queensland, Proc., 48 (1936), pp. 3-19*).—This presidential address reviews the progress of work in entomology in Queensland, with a list of 21 references to the literature.

[Insect pests of the cotton crop in Java], C. J. H. FRANSSEN and H. R. A. MULLER (*Landbouw [Buitenzorg], 14 (1938), No. 5-6, pp. 321-362, figs. 46; Eng. abs., pp. 361, 362*).—Some 23 species of insects that attack the cotton crop in Java are noted. Most of these are minor pests but 5 of them occasionally cause serious damage, namely, the weevils *Hypomeces squamosus* and *Amorphoidea pectoralis*, the spiny bollworm *Barias fabia*, the pink bollworm, and a leafhopper of the genus *Empoasca*.

[Contributions on fruit insects and their control] (*Missouri State Hort. Soc. Proc., 1935-36, pp. 116-147, fig. 1; 1937-38, pp. 213-215*).—Among the contributions presented in the proceedings for 1935-36 are The Codling Moth Situation, by L. Haseman (pp. 116-119), and Spray Injury, by H. G. Swartwout (pp. 125-132) (both Univ. Mo.); The Red Spider on Apples, by H. Baker (pp. 119-124) (U. S. D. A.); and Summer Oils, by C. R. Cleveland (pp. 133-147); and for 1937-38, Effects of Weather on Insect Problems, by L. Haseman (pp. 213-215) (Univ. Mo.).

Dormant season spraying: Trees and shrubs, C. C. HAMILTON (*New Jersey Stat. Cir. 389 (1939), pp. 4*).—A practical discussion.

The hurricane and the newer shade tree insect problems, E. P. FLIT and S. W. BROMLEY (*Jour. Econ. Ent., 32 (1939), No. 2, pp. 203-205*).

Shade tree insects of the Mid-West, W. P. FLINT and M. D. FARRAR (Ill. Expt. Sta. et al.). (*Natl. Shade Tree Conf. Proc., 14 (1938), pp. 94-106*).—A practical discussion.

Controlling house plant pests, C. C. HAMILTON (*New Jersey Stat. Cir. 388 (1939), pp. 4*).—A brief practical account.

Insect pests of derris, R. C. ROARK (U. S. D. A.). (*Jour. Econ. Ent., 32 (1939), No. 2, pp. 305-309*).—A classified list of insects, attacking derris, compiled by the author, is presented with 39 references to the literature cited.

Sedimentation and microprojection methods for determining particle-size distribution of insecticidal materials, L. D. GOODHUL and M. L. GOODEN (U. S. D. A.). (*Jour. Econ. Ent., 32 (1939), No. 2, pp. 324-339, figs. 3*).—The particle-size distribution of three commercial samples of sulfur was determined by sedimentation and by microprojection. It is concluded that as far as precision is concerned "there is probably no choice between the methods, but the comparative ease with which results can be obtained by sedimentation should give this method preference for most insecticidal materials. Improvements in apparatus for both methods are described."

Dormant spray problems in New York, F. Z. HARTZELL (N. Y. State Expt. Sta.). (*Jour. Econ. Ent., 32 (1939), No. 2, pp. 274-277*).—Dormant spray problems, including materials and mixtures and the question of fall v. spring applications in regard to materials and mixtures, are considered. A summary is given of the results secured.

Insecticides to control insect pests in Jamaica, W. H. EDWARDS (*Jamaica Dept. Sci. and Agr. Bul. 6, n. ser. (1936), pp. [5]-50, pls. 4, figs. 11*).—A practical account of insecticides, methods of application, and the types of apparatus applicable to Jamaica conditions.

Mineral oils as insecticides, J. CARROLL (*Roy. Dublin Soc., Econ. Proc.*, 3 (1938), No. 5-6, pp. 63-74).—This is a practical summary of the present status of mineral oils as insecticides.

Control of apple aphids and European red mite by coal tar oil and other materials, H. N. WORTHLEY and H. M. STEINER. (Pa. Expt. Sta.). (*Jour. Econ. Ent.*, 32 (1939), No. 2, pp. 278-286, figs. 3).—Experiments conducted have shown that high temperature coal-tar creosote emulsions (tar produced at 925°-1,000° C.) are effective sprays for "the control of several fruit tree and other pests, but they are caustic in nature, of questionable value against eggs of the European red mite, and appear to depress the action of lubricating oils against the eggs of this species. A low temperature coal-tar creosote emulsion (tar produced at 450°-500°) differs from the high temperature material chiefly in its higher percentage of tar acids (of high boiling range) and of paraffins and its lower percentage of aromatics. This material appears to be less caustic than the high temperature tar oils. It is as effective as the latter against aphid eggs, and in mixture with lubricating oil it seems to have less depressing effect on the toxicity of the petroleum oil to red mite eggs. It has not been tested against other insects subject to control by tar oils.

"Really adequate control of the European red mite has not been demonstrated by any of the materials reported. However, the mixtures of low temperature tar oil and lubricating oil, and of lubricating oil with added toxicants, merit further study. However, dinitro-*o*-cyclohexylphenol and sodium dinitro-*o*-cresylate appear to be only slightly toxic to eggs of the European red mite. From the standpoint both of injury and effectiveness, lubricating oil emulsified with bordeaux mixture should be tried further in the green tip and delayed dormant stages of tree development. Difficulties in the evaluation of early season sprays against the European red mite are pointed out in this paper."

Possible changes in ratio of lead to arsenious oxide in lead arsenate residues on apples, J. E. FAHEY and H. W. RUSK. (U. S. D. A.). (*Jour. Econ. Ent.*, 32 (1939), No. 2, pp. 319-322).—Report is made of experiments conducted in southern Indiana in 1935 and 1936 to determine the extent of decomposition of lead arsenate spray residues on apples as measured by their ratios of lead to arsenious oxide. "The residues were analyzed immediately after the various cover-spray applications and again after the residues had weathered. A total of 248 samples of apples and apple foliage were used. The average ratio of lead to arsenious oxide in these samples did not vary significantly from that in the original spray material, and samples taken immediately after spraying showed no significant difference from those taken after weathering. The slight variations between the ratios are in reality the combined analytical errors of the methods of residue analysis. The high ratios obtained by early investigators are due probably to inadequate samples or to unreliable methods of analysis."

Dormant spray mixtures on conifers, F. L. GAMBRELL and F. Z. HARTZELL. (N. Y. State Expt. Sta.). (*Jour. Econ. Ent.*, 32 (1939), No. 2, pp. 206-209).—The results of several years' investigations of the plant tolerance of conifers to dormant and summer sprays and the toxicity of these materials to certain insects are reported. It was shown that DN-oil (lubricating oil containing 2 or 4 percent of dinitro-*o*-cyclohexylphenol) and Elgetol at concentrations greater than 1 gal. in 100 gal. of spray mixture are likely to be attended with serious injury on evergreen conifers. There is also a possibility that 1 gal. of DN-oil or of Elgetol per 100 gal. of spray mixture "may prove injurious under certain conditions such as heavy drenching sprays, adverse weather, or low tree vigor. One- and 3-percent concentrations were used because previous experiments had

shown these amounts to be the lower and upper limits of concentration necessary for the control of certain fruit insects."

Progress report on damage done in the Kingston and St. Andrew area by termites which infest buildings, W. H. EDWARDS (*Jamaica Dept. Sci. and Agr. Bul. 10, n. ser. (1937), pp. 11*).—A progress report of the study of termites, the damage to buildings by which in recent years in Jamaica has increased to a marked extent.

Construction of metal termite shields, N. TURNER (Conn. [New Haven] Expt. Sta.). (*Pests, 7 (1939), No. 2, pp. 16, 17*).

Getting rid of termites in banked citrus trees, J. R. WATSON (*Citrus Indus., 19 (1938), No. 12, pp. 8, 23*).

Stomach poisons and the two-striped grasshopper: Special reference to arsenic and fluorine compounds, C. H. RICHARDSON and E. J. SEIFERLE (Iowa Expt. Sta.). (*Jour. Econ. Ent., 32 (1939), No. 2, pp. 297-300, figs. 3*).—Report is made of eight chemical compounds that were tested in the laboratory as poison in bran-water-molasses baits against adults of the two-striped grasshopper. "Dosage was accomplished by an individual feeding method. The median lethal dose for arsenic trioxide was 0.026 mg. per gram of body weight; for sodium arsenite as NaH_2AsO_4 , 0.015 mg. per gram and as As_2O_3 , 0.0095 mg. per gram; for sodium fluosilicate 0.10 mg. per gram; and for sodium fluoride 0.04 mg. per gram, the latter being an approximation. The susceptibility of two other species of grasshoppers to these poisons is discussed. Cryolite (sodium fluoaluminate) and barium fluosilicate in bran baits were apparently rather toxic to this insect, but the data were not sufficient to determine the median lethal doses. Chloroacetamide was lethal at relatively low doses but appeared to be rather repellent. On the other hand, phenothiazine was nontoxic at doses as high as 5.8 mg. per gram. Sodium arsenite gave the shortest survival time, sodium fluoride the longest, while sodium fluosilicate and arsenic trioxide occupied an intermediate position."

The plague grasshopper *Austroicetes jungi* Brancsik, C. F. H. JENKINS (*Jour. Dept. Agr. West. Austral., 2. ser., 14 (1937), No. 4, pp. 367-380, figs. 6*).—This contribution deals with the species that has been responsible for the most damage in the agricultural districts of Western Australia, its morphology, biology, and control.

Further notes on the control of the harlequin bug, H. G. WALKER and L. D. ANDERSON (Va. Truck Expt. Sta.). (*Jour. Econ. Ent., 32 (1939), No. 2, pp. 225-228*).—In further studies (E. S. R., 60, p. 77) cage and field tests have shown that "thoroughly spraying plants infested with harlequin bugs with a mixture containing 4 lb. of derris or cube powder (rotenone content 5 or 6 percent) to 50 gal. of water, to which a good wetting agent has been added, will give good control of all harlequin bugs hit by the spray. Further, 1 part of Stantex R emulsified in 50 parts of water and thoroughly applied will give good control of this pest, as will the concentrated derris extract plus soap spray previously recommended. On large plants where the bugs are well protected it may be necessary to spray two or three times at weekly intervals to insure good control."

Studies of rice stinkbug [*Solubea pugnax* (F.)] populations, with special reference to local migration, W. A. DOUGLAS (U. S. D. A.). (*Jour. Econ. Ent., 32 (1939), No. 2, pp. 300-303, figs. 2*).—A report of work with the rice stinkbug *S. pugnax*, a common insect in rice fields in Louisiana, Texas, and Arkansas each year, shows that it is one of the most important insect pests of this crop.

The tarnished plant bug as an apple pest, O. H. HAMMER (N. Y. State Expt. Sta.). (*Jour. Econ. Ent., 32 (1939), No. 2, pp. 259-264, figs. 4*).—Studies,

on a curious type of dimpled injury, found during the past few years on apple fruits in eastern New York fruit districts and caused by feeding punctures of the tarnished plant bug, are reported.

Food habits of *Phymata pennsylvanica americana* Melin (Hemip.), W. B. BALDUF. (Univ. Ill.). (*Canad. Ent.*, 71 (1939), No. 3, pp. 66-74).—Observations on the insect-preying habits of *P. pennsylvanica americana* are reported in table form.

Discussion on recent advances in methods of bed-bug disinfestation, [I, II] (*Jour. Roy. Sanit. Inst.*, 58 (1938), No. 9, pp. 535-555).—The first contribution is presented by S. A. Ashmore (pp. 535-544) and the second by B. T. J. Glover (pp. 545-555), both of whom are led to conclude that heavy coal-tar naphtha, a clear odorless liquid, is an effective remedy for the bedbug. It can be used without danger to man, and the isolation of neighboring houses and tenements is unnecessary. It is cheap, easily applied, and readily available, and has no harmful action on fittings, furniture, or furnishings.

A new *Rhagovelia* from Cuba, C. J. DRAKE and H. M. HARRIS (*Pan-Pacific Ent.*, 14 (1938), No. 4, p. 152).

Egg parasites of the cotton flea hopper, K. P. EWING and H. J. CRAWFORD. (U. S. D. A.). (*Jour. Econ. Ent.*, 32 (1939), No. 2, pp. 303-305).—Report is made particularly of the rearing and observation of two parasites of the eggs of the cotton flea hopper, namely, *Anaphes anomocerus*, a previously reported egg parasite of the garden flea hopper, and a new species described by Gahan as *Erythmus pallidis* (E. S. R., 79, p. 663).

Pyrethrum and derris as a control for the six-spotted leafhopper, a vector of lettuce yellows, B. B. PEPPEL and C. M. HAENSELME. (N. J. Expt. Stas.). (*Jour. Econ. Ent.*, 32 (1939), No. 2, pp. 291-296, figs. 3).—Fencing to protect lettuce from the attack of the six-spotted leafhopper, which transmitted the virus of lettuce yellows disease, was successful in 1937 in that "only 1 percent of the protected lettuce showed symptoms of the disease, while the loss in the check plots was 31.8 percent. Small plot experiments with insecticides in 1936 and 1937 showed that a very high degree of leafhopper control was possible, while the decrease in the disease was very slight. This was thought to be due to migration of the adult leafhopper. In large plot experiments conducted in 1938 rotenone and pyrethrum dusts gave good control of the leafhopper, which in turn reduced the amount of the virus to the extent that a commercial crop of lettuce was harvested. Roguing, although not so effective as insecticides, has given approximately 50 percent reduction in lettuce yellows."

Studies on rice leaf-hoppers.—I, Biology and natural enemies, T. ISAKI and S. HASEGAWA (*Japan Min. Agr. and Forestry, Dept. Agr., Nijikairyoshiryō No. 127* (1937), pp. [3]+135, pls. 15, figs. 9; *Eng. abn.*, pp. 130-135).—A summary is given of the results of an investigation of leafhoppers injurious to the rice plant in Japan. Of the 14 species representing 4 families that were observed in rice fields in the vicinity of Fukuoka, Kyushu, the Jassids *Nephotettia bipunctatus cincticeps* (Uhler) and *Dolicocephalus dorsalis* (Motsch.) and the delphacids *Delphacodes striatellus* (Fall.), *Sogatia furcifera* (Horv.), and *Nilaparvata oryzae* (Mats.) were found to be important.

The element of timing in relation to pea aphid control, H. GLASGOW. (N. Y. State Expt. Sta.). (*Jour. Econ. Ent.*, 32 (1939), No. 2, pp. 234-240, figs. 2).—Observations of the relation of aphid population to crop damage and to yield of peas, a suggested plan for timing experiments in pea aphid control studies, and timing as applied to pea aphid control are considered.

Dinitro-o-cresol, dinitro-o-cyclo-hexylphenol, and lauryl rhodanate in dormant sprays against eggs of apple aphids, W. S. HOUSE. (Va. Expt.

Sta.). (*Jour. Econ. Ent.*, 32 (1939), No. 2, pp. 264-270).—Experiments reported have shown dinitro-*o*-cresol, its soluble salt sodium dinitro-*o* cresylate, dinitro-*o*-cyclohexylphenol, and lauryl rhodanate to be effective ovicides for aphid eggs occurring on apple trees. "These compounds compared favorably with coal tar distillate in their ovicidal action on aphid eggs. Sodium dinitro-*o* cresylate (dinitro-*o*-cresol at 2.5 to 2.9 lb. per 100 gal.) was effective when applied in January, February, or March. Dinitro-*o*-cyclohexylphenol in oil was effective in fall and spring applications when used at concentrations of not less than 9.5 oz. per 100 gal. of diluted spray. Lighter concentrations (4.9 to 7.4 oz.) in fall applications usually gave inadequate control. Dinitro-*o*-cyclohexylphenol in water suspensions showed high toxicity to aphid eggs when applied in March. Lauryl rhodanate was toxic to aphid eggs and also to apple buds. Its phytocidal action was sufficiently severe to eliminate it from further consideration."

Control of whiteflies on gardenias, L. D. ANDERSON and H. G. WALKER. (Va. Truck Expt. Sta.). (*Jour. Econ. Ent.*, 32 (1939), No. 2, pp. 210-213).—In experiments conducted, the details of which are given in tables, the citrus whitefly was satisfactorily controlled on gardenias "by thorough spraying with 1- and 2-percent solutions of Stantex R emulsified with soap, a 4-percent solution of Elgeté, and 6 $\frac{3}{4}$ -, 4-, and 2-percent fish oil emulsions, while Ortho Brand Garden Volk and weaker solutions of Stantex R, Elgeté, and fish oil did not give satisfactory control. Also, fish oil was a disagreeable material to handle, and it gave some foliage injury under certain conditions."

Some possible reasons for the increase of purple scale infestations, W. L. THOMPSON. (Fla. Expt. Sta.). (*Citrus Indus.*, 19 (1938), No. 12, pp. 6, 7, 17, 20).

Advisability of treating picking boxes to prevent red scale spread, H. J. QUAYLE. (Calif. Citrus Expt. Sta.). (*Calif. Citroy.*, 24 (1939), No. 3, p. 111).

Notes on the biology of the Great Basin tent caterpillar *Malacosoma fragilis* Stretch (Lep., Lasiocampidae), R. B. SWAIN (*Canad. Ent.*, 71 (1939), No. 3, pp. 76, 77).—The tent caterpillar *M. fragilis* noted occurs in the Rocky Mountain region of the United States, where it feeds on a large variety of deciduous trees and shrubs and is the most abundant member of the genus found therein.

Sweet corn variety tests in relation to corn earworm damage at Norfolk, Virginia, H. G. WALKER and L. D. ANDERSON (*Virginia Truck Sta. Bul.* 100 (1938), pp. 1579-1593).—Experiments commenced in 1934 to test the resistance of some of the newer varieties of sweet corn in comparison with that of a large number of other varieties that are commonly grown for roasting ear corn in Tidewater Virginia, where serious damage by the corn earworm has prevented the profitable production of sweet corn, are reported. There were wide variations in the severity of its injury to the 64 varieties of sweet and field corn grown in these tests. "In general, freedom from injury seemed to be associated with thick, close-fitting husks and with late maturity. There was some indication in tests conducted in 1937 and 1938 that corn planted to mature between July 15 and August 5 would be less seriously injured than corn planted to mature either earlier or later than these dates. The early maturing varieties tested were all so badly injured that it is doubtful if it would be practical to grow them on a commercial scale. Some of the later maturing sweet corn varieties such as Honey June, Surcropper Sugar, Money Maker, Aunt Mary, Redgreen Hybrid, Oregon Evergreen, Topcrossed Evergreen, Stowell Evergreen, and Golden Cross Bantam have produced a relatively high percentage (69 to 98 percent) of ears free from serious corn earworm damage when planted in April and May." It is pointed out that frequently corn planted after about the middle of June is

so badly injured by the corn earworm and the fall armyworm that late planting cannot be safely recommended.

This is given with a list of 13 references to the literature.

Control of sod webworms in lawns, II. H. JEWETT (*Kentucky Sta. Bul.* 391 (1939), pp. 89-106, figs. 4).—A study of control measures for sod webworms, especially in lawns, commenced in the spring of 1934, is reported upon. The forms commonly found in bluegrass sod in Kentucky are the bluegrass sod webworm *Ombus teterrellus*, the striped sod webworm *O. mutabilis*, and the leather-colored sod webworm *O. trisectus*. Observations of adults at lights indicate two broods and a possible third for *O. teterrellus*, and two broods for the other two species. Work with insecticides has included the use of pyrethrum, kerosene emulsion, lead arsenate, dichloroethyl ether, barium carbonate, nicotine oleate, derris, "loro," "lethane, jr.," and poison bait. A spray containing pyrethrum was most effective for their control in bluegrass sod. "A pyrethrum extract containing 2 gm. of pyrethrins in 100 cc. should be diluted at the rate of 1 oz. to 4 gal. of water and applied at the rate of 2 gal. to 20 sq. ft. A kerosene emulsion made of $\frac{1}{2}$ lb. of hard soap, 1 gal. of water, and 2 gal. of kerosene may be used with good results at a dilution of 1 part to 10 of water, applied at the rate of 2 gal. to 20 sq. ft. The emulsion must be very carefully prepared to prevent injury to the grass. Lead arsenate 2 lb. in 20 gal. of water was fairly effective when applied at the rate of $2\frac{1}{2}$ lb. to 1,000 sq. ft. Soap or some other material should be added to the spray to make the lead arsenate stick to the grass." The results of some spraying experiments are given in appended tables.

Biological control of the sugarcane moth borer in Puerto Rico, K. A. BARTLETT. (U. S. D. A.). (In *The Puerto Rico Sugar Manual*. New Orleans, La.: A. B. Gilmore, 1938, pp. 7-9).—Progress in the introduction of natural enemies of the sugarcane moth borer in Puerto Rico is reported.

Studies on the control of rice borers.—II, Studies on the chemical control of the rice borer (*Chilo simplex* Butler), I. MORINO, K. HOMMA, T. TANIGUCHI, and N. ANDŌ (*Japan Min. Agr. and Forestry, Dept. Agr., Nōjikkōshiryō No. 115* (1936), pp. [3]+2+154+4, pls. 14, figs. 8; Eng. abs., p. 154).—Chloropicrin used at the rate of 1.5 lb. or a little more for 1,000 cu. ft. for 2 days or longer has been found to be the most satisfactory fumigant for control of the overwintering larvae of the Asiatic rice borer in lumps of straw. The use of nicotine, although injurious to hymenopterous egg parasites, is very effective in the destruction of eggs, larvae, and moths of this pest and in preventing oviposition and the entrance of the larvae into the haulms.

Orange tortrix: A damaging pest of citrus, A. J. BASTINGER. (Calif. Citrus Expt. Sta.). (*Calif. Citrog.*, 24 (1939), No. 6, p. 201, figs. 3).

The distribution, status, and biology of codling moth (*Cydia pomonella* L.) in Baluchistan, with notes on some other insects infesting apples, ILM SINGH PRUTHI (*Indian Jour. Agr. Sci.*, 8 (1938), No. 4, pp. 499-547, pls. 7, fig. 1).—This report of a study of the distribution, status, and biology of the codling moth, details of which are appended in numerous tables, includes information on three additional forms that attack apples in Baluchistan, namely, *Spilonota ocellana* Schiff., *Euzophera puniceella* Moore, and *Cacoecia sarcostega* Meyr. Plates illustrating the several stages and the nature of the work of these four pests, three of which are in colors, are included.

[Efficiency of sprays for codling moth in the Northwest] (Better Fruit, 33 (1939), No. 7, pp. 6, 14, 15).—Reference is made to contributions on spraying for codling moth control, including costs, materials, effectiveness, and cleaning, presented by J. Marshall, F. L. Overley, and E. J. Newcomb at the annual meeting of the Washington State Horticultural Society held at Yakima.

Effect of particle size of some insecticides on their toxicity to the codling moth larva, E. H. SIEGLER and L. D. GOODHUE. (U. S. D. A.). (*Jour. Econ. Ent.*, 32 (1939), No. 2, pp. 199-203, fig. 1).—Details of work on the effect of particle size on the toxicity of five insecticides to the codling moth larva are reported in tables. Three fractions each, graded as to particle size into "fine, medium, and coarse, of calcium arsenate, paris green, cryolite (synthetic), and phenothiazine, and two fractions of acid lead arsenate were tested in replicated series. Except for phenothiazine, no great difference in toxicity of the different fractions was obtained, but the medium fraction was generally slightly superior. In the case of lead arsenate, the coarse fraction was somewhat more effective than the fine (no medium fraction was prepared). The coarse fraction of phenothiazine was much less toxic than was the fine or the medium fraction."

Effect of copper fungicides on lead-arsenate-lime and fixed nicotine-oil sprays for codling moth, L. A. STEARNS, K. J. KADOW, and M. W. GOODWIN. (Del. Expt. Sta.). (*Jour. Econ. Ent.*, 32 (1939), No. 2, pp. 270-273).—Spraying experiments conducted in 1938 and other findings of the year indicate that an apple spraying program "(with, of course, certain varietal limitations), including prebloom applications of liquid lime-sulfur (or possibly a combination of liquid lime-sulfur and flotation sulfur), with flotation sulfur, lead arsenate, and hydrated lime in the petal fall and first cover sprays, followed by successive applications of a relatively weak bordeaux mixture with lead arsenate, is best designed to meet the exacting requirements of effective control of diseases and insects under Delaware conditions without serious spray injury on foliage and fruit."

Experiments with nicotine for the control of codling moth, B. F. DEIGERS and W. J. O'NEILL. (N. J. Expt. Stas.). (*Jour. Econ. Ent.*, 32 (1939), No. 2, pp. 286-290).—Tests carried on over a period of 2 yr. with a triple spray of nicotine sulfate, oil and lead arsenate, or fixed nicotine, aimed at reducing first brood of codling moth to such a low point that little or no second brood spraying will be necessary, show that "the addition of a pint of nicotine sulfate (Black Leaf 40) to 100 gal. of a spray mixture containing an ovicide and larvicide definitely improves the control. Lead arsenate proved more effective as the larvicide than fixed nicotine. Spraying from the outside of the tree using multiple nozzle rods as opposed to spraying from the ground with single nozzle guns tended to trap the adult moths in the trees, thus increasing the adult moth kill and resulting in better control. Observations indicated that the full effects of the triple spray treatments were not obtained because moths drifted in from adjoining blocks of trees."

A preliminary survey of mosquitoes in North Dakota, J. A. MUNRO and S. SAUGSTAD (*North Dakota Sta. Bimo. Bul.*, 1 (1939), No. 5, p. 7).—In a preliminary survey of the mosquitoes of the State the presence of 11 species representing 5 genera of Culicidae was determined. Two of the species, namely, *Aedes dorsalis* and *A. nigromaculis*, are known to be capable of transmitting the virus of equine encephalomyelitis from one animal to the other.

Biologies of Arkansas rice field mosquitoes, H. H. SCHWARDT (*Arkansas Sta. Bul.* 377 (1939), pp. 22, figs. 5).—The importance of mosquitoes in the rice region of Arkansas, which suffers particularly from June 1 to September 15, led to the biological study of *Psorophora columbiae*, representing 90 percent of those present, and *P. ciliata*, *P. discolor* and the common malarial mosquito, representing most of the remaining 10 percent. The observations were conducted in Arkansas County.

Mosquitoes of the Ethiopian region, I, II (London: Brit. Mus. (Nat. Hist.), 1936, vol. 1, pp. [6]+250, figs. 158; 1938, vol. 2, pp. X+404, figs. 174).—

The first volume of this monograph of the Culicidae of the whole of the Ethiopian region, including Africa south of the Sahara, together with Madagascar and the Mascarene Islands and southwest Arabia, by G. H. E. Hopkins, takes up the larval bionomics of mosquitoes and taxonomy of culicine larvae. The second volume, which is by A. M. Evans, reports upon Anophelini adults and early stages, with descriptions by F. W. Edwards of three new species.

Some conservation and ecological aspects of mosquito control, E. N. COBY and S. L. CROTHWAIT. (Univ. Md.). (*Jour. Econ. Ent.*, 32 (1939), No. 2, pp. 213-215).

Comparative results obtained by the use of several mosquito traps in a limited area, D. MACCREARY. (Del. Expt. Sta.). (*Jour. Econ. Ent.*, 32 (1939), No. 2, pp. 216-219, fig. 1).—In work reported, the details of which are given in two tables, five mosquito traps were operated in various locations in a comparatively small community for 27 consecutive days during July 1937. Of the mosquitoes collected nearly 63 percent were females. Approximately 60 percent of *Aedes vexans*, which constituted nearly one-fourth of the total catch, were females. The northern house mosquito and *Culex salinarius* together comprised 65 percent of all material, and of this number 60 percent were females. It was evident, however, from the data presented that there is more flight activity among male mosquitoes than is generally believed. It was also apparent that if unusual topographical or sanitary conditions do not exist, one trap properly located would be sufficient to provide an accurate estimate of mosquito density in a community of 4,500 population.

How petroleum oil kills certain mosquito eggs, G. E. POWERS and T. J. HEADLEE. (N. J. Expt. Stas. et al.). (*Jour. Econ. Ent.*, 32 (1939), No. 2, pp. 219-222, figs. 2).—Work reported, the details of which are given in tables, led to the conclusion that "eggs of *Aedes aegypti* are killed when coated with petroleum oil by oxygen starvation. The more nearly perfect the oil coating the more quickly the kill is accomplished. The variation in killing power of different petroleum oils is probably a factor of either too short a period of oil retention or a failure of the oil to make a closely applied and complete seal."

New Jersey mosquito larvicide, J. M. GINSBURG (*New Jersey Stas. Cir.* 382 (1939), pp. 4).—A practical account of the use of New Jersey Pyrethrum Mosquito Larvicide developed by the station in 1930 (E. S. R., 64, p. 160; 70, p. 509).

Experimental diking for control of sand fly and mosquito breeding in Florida salt-water marshes, J. B. HULL, W. E. DOVE, and N. G. PLATTS. (U. S. D. A. et al.). (*Jour. Econ. Ent.*, 32 (1939), No. 2, pp. 309-312).

New and little known Utah Pipunculidae (Diptera), D. E. HARDY and G. F. KNOWLTON. (Utah Expt. Sta.). (*Canad. Ent.*, 71 (1939), No. 4, pp. 87-91, figs. 18).—Notes are given on seven forms of big-eyed flies of the genus *Pipunculus*, of which three intermountain species and two varieties are described as new. The larvae of these flies frequently parasitize meadow and range leafhoppers to an important extent.

Experimental studies on the influence of low temperatures upon the development of fruit-flies.—X, Effect of varying low temperatures upon the emergence of larvae and pupae of *Chaetodacus ferrugineus* var. *dorsalis* Hendel, K. KOMSUMI (*Jour. Soc. Trop. Agr. (Nettai Nôgaku Kwaishi)*, 9 (1937), No. 4, pp. 411-417).—A continuation of the series previously noted (E. S. R., 78, p. 828).

A study of the African species of Platensini, a tribe of the family Trypetidae (fruit-flies, Diptera), H. K. MUNRO (*Union So. Africa Dept. Agr. and Forestry, Ent. Mem.*, 2 (1937), No. 1-2, pp. 5-28+[1], figs. 5).—A synopsis of an important tribe of fruitflies in which four genera are erected and three species described as new.

Studies in Australian and oriental Trypanidae.—I, New genera of Dacinae, F. A. PERKINS (*Roy. Soc. Queensland, Proc.*, 48 (1936), pp. 51-60).—The author erects six new genera and describes one new species in this contribution on the Australian species of trypanid fruitflies.

Heat sterilization of Formosan fruits for fruit-flies, I-III, K. KOMSUMI (*Jour. Soc. Trop. Agr. (Nittai Nōgaku Kwaishi)*, 8 (1936), No. 2, pp. 157-175; 9 (1937), No. 3, pp. 275-286).—Part 1 of these contributions, all in Japanese, reports upon preliminary determinations on the thermal death points of *Chaetodacus ferrugineus dorsalis* Hendel and *C. cucurbitae* Coq. (pp. 157-165); part 2, the results of tests of the effect of heat on "tankan" (*Citrus tankan*) (pp. 166-175); and part 3, on plum, mango, zaban (*C. maxima*), and ponkan (*C. poonensis*) (pp. 275-286).

Studies on repellents for biting flies, C. B. MACNAY (*Canad. Ent.*, 71 (1939), No. 2, pp. 38-44).—The results of findings of the repellent action of various materials employed against common species of *Aedes* are reported, the details being given in table form.

The development of immunity in cavies to the larvae of Cochliomyia americana C. & P., E. W. LAAKE and C. L. SMITH. (U. S. D. A.). (*Jour. Econ. Ent.*, 32 (1939), No. 2, pp. 339-342).—In the authors' studies, the number of screwworm larvae constituting a maximum sublethal and a minimum lethal initial infestation in the average cavy was found to be two and three, respectively, per hectogram of body weight. "The immunity or enhanced tolerance developed in cavies to *C. americana* larvae from initial maximum sublethal and from three reinfestations was determined. The amount so developed is approximately 50 to 100 percent greater than that of uninfested animals and is the result of the initial infestation. No substances deleterious to the larvae were developed by cavies from initial infestations or by as many as three reinfestations. In cavies either the extension of a local immunity or the establishing of a systemic immunity by previous infestations of screwworms was demonstrated. On the basis of a small number of animals tested, it is indicated that no enhanced tolerance to *C. americana* is inherited by cavies born of infested parents. Other than a slight retardation of death, no tolerance to *C. americana* greater than that occurring in normal cavies was produced by injections of sterile suspensions of mature tub-reared *C. americana* larvae and of *Proteus chandleri*."

Some common beetles on roses and other flowering plants, C. C. HAMILTON (*New Jersey Stat. Cir.* 390 (1939), pp. 3).—A brief practical account.

The respiratory metabolism of starved Japanese beetle larvae (Popillia japonica Newman) at different relative humidities, R. BELLUCCI (*Physiol. Zool.*, 12 (1939), No. 1, pp. 50-56, fig. 1).—The observations here reported show the time of survival of the Japanese beetle larvae to depend upon the humidity. "At 0-5 percent they lived 4 days, at 56 percent they lived 12 days, and at 96 percent they lived 26 days. In these experiments death was caused by starvation at a humidity of 96 percent and by desiccation at the lower humidities. The larvae exposed to 0-5 percent humidity died with an average water content of 53.2-54.5 percent, indicating that death was caused by desiccation, and at 96 percent humidity they died of starvation, with a water content of 75.9 percent. Starvation caused the metabolic rate to fall rapidly during the first 2 days and then more slowly, fluctuating about a low level which was maintained until death. The rapid decrease in the metabolic rate to a low point, barely sustaining life, may be the factor allowing the larvae to live as long as a month at high humidities without food. There is a decrease in the respiratory quotient from an average of 0.92 to 0.70, indicating the oxidation of stored fats during starvation. Different relative humidities or the water content of

the larvae have no direct effect on the respiratory metabolism. The observed fall in the rate of oxygen consumption is due to starvation."

A review of cooperative Japanese beetle retardation work in Maryland, (J. S. LANGFORD, S. L. CROSTHWAITE, and F. B. WHITTINGTON. (Univ. Md.). (*Jour. Econ. Ent.*, 32 (1939), No. 2, pp. 255-259).

Further investigations with Japanese beetle repellents, H. G. GUY and H. F. DIERZ (*Jour. Econ. Ent.*, 32 (1939), No. 2, pp. 248-252).—In continuation of earlier work (H. S. R., 77, p. 76), report is made on a new composition of tetramethylthiuram disulfide, which greatly improved the retention of the active agent. "The outstanding treatment was 5 lb. of this new tetramethylthiuram disulfide composition, which contained 20 percent inert ingredients. Two and one-half lb. of this mixture was much more effective than 4 lb. of derris. With the possible exception of zinc or aluminum sulfate and lime, all other stickers investigated reduced the efficiency of this tetramethylthiuram disulfide composition. Tetramethylthiuram disulfide was found to react with copper and should not be used in combination with bordeaux mixture, or before or after bordeaux or other copper sprays. It can be safely mixed with lead arsenate, hydrated lime, wettable sulfur, phenothiazine, or derris. Phenothiazine remains of interest and might have the added advantage of controlling codling moth in areas where this insect is a serious problem."

Japanese beetle control tests on American elm trees in Delaware, R. L. PRERFONT. (Del. Expt. Sta.). (*Jour. Econ. Ent.*, 32 (1939), No. 2, pp. 253-255).—The author concludes from the work conducted that either ground derris (4 lb.) or tetramethylthiuram disulfide (5 lb.), combined with a suitable adhesive such as rosin residue emulsion, is at present the most effective protectant for the foliage of American elm trees against the ravages of the Japanese beetle. "These combinations may be used without fear of injury to, or a building up of conspicuous residue on, such trees. An application should be made prior to any heavy invasion by this insect, and the spray should be repeated as soon as any reinfestation is noted."

Control of the Japanese beetle on ornamental plants, C. C. HAMILTON (*New Jersey Stat. Cir.* 387 (1939), pp. 4).—A practical account.

Schizonotus sieboldi, an important parasite of the imported willow leaf beetle *Plagiodera versicolora*, P. B. DOWDEN. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 58 (1939), No. 8, pp. 581-592, figs. 3).—Following a review of the literature, accompanied by a list of 13 references, an account is given of the distribution and host relationships, economic importance, morphology, biology and habits, and superparasitism and secondary parasitism of *S. sieboldi*, a primary parasite of *P. versicolora* and some other closely allied leaf-eating beetles (Chrysomelidae). This parasite is well distributed throughout Europe and the United States and is apparently present wherever the beetle occurs in this country. While high percentages of parasitization have been noted over a 3-yr. period in the vicinity of Boston, Mass., about the same degree of host infestation seems to have been maintained.

The immature stages of *S. sieboldi* have been described in some detail. They are very similar to those of the pteromalids *Dibrachys cavus* (Walk.) and *Habrocytus cerealellae* (Ashm.).

"The winter is spent as an adult. Two and sometimes three generations develop during the summer. The females live, mate, and oviposit well under laboratory conditions. The maximum number of eggs laid by one female was 424. The eggs are laid singly on the venter of the host pupa, and the larvae feed externally. About 15 days is required from egg deposition to adult emergence. On an average two individuals develop on one *Plagiodera* pupa. The proportion of the sexes is equal.

"Two hyperparasites, *Tetrastichus* n. sp. and *Pleurotropis tarsalis* (Ashm.), have been reared from *Schizonotus* pupae. At times *Tetrastichus* is an important enemy of *Schizonotus*."

The life-history of *Nothopeneus hemipterus* Oliv. and its control. C. J. H. FRANSSEN (*Landbouw [Buitenzorg]*, 13 (1937), No. 12, pp. 569-586, figs. 2, Eng. abs., pp. 585, 586).—Report is made of a study of the biology of *N. hemipterus*, one of three related species of longicorn stemborers of the clove tree in the Dutch East Indies.

Life cycle and food requirements of the northern grain wireworm *Ludius aereipennis destructor* Brown. E. H. STRICKLAND (*Jour. Econ. Ent.*, 32 (1939), No. 2, pp. 322-329).—Report is made of completed life cycle studies of *L. aereipennis destructor* which have shown that in field cages in which conditions approximate "those occurring in the field, the length of the life cycle and the rate at which the individual wireworms develop is very variable. The shortest period required for the completion of the life cycle was 4 yr. and the longest, 9 yr. The rate of growth, particularly during the first 3 yr. after hatching, is very erratic. In a typical cage, 15-month-old larvae varied in length from 4.5 to 12 mm. These differences are reduced in subsequent years, and a rapid early development is of no significance with regard to the number of years required for development or to the ultimate size of the adult beetle. The number of larval instars varies from 10 to at least 24. Newly emerged larvae die from starvation in a few weeks unless they have access to suitable living vegetation. More mature wireworms can live for at least 3 yr. in soil in which no vegetation is present. It is, therefore, impractical to attempt to starve wireworms in any year except that in which they have hatched. Monocotyledonous vegetation, alone, meets the requirements of these young larvae, though a small percentage may survive on a few dicotyledonous plants. These facts have a direct bearing on the problem of reducing wireworm populations by starving newly emerged larvae in summer fallow."

Toxicity studies of so-called "inert" materials with the bean weevil (*Acanthoscelides obtectus* (Say)), S. F. CHRU. (Cornell Univ.). (*Jour. Econ. Ent.*, 32 (1939), No. 2, pp. 240-248, figs. 4).—Laboratory experiments, the results of which are presented in tables, have shown that certain so-called inert materials when applied as dusts are effective in killing adult bean weevils. Of six different inert materials tested, bentonite was most effective, followed in order by magnesium carbonate, crystalline silica, amorphous silica, talc, and walnut-shell flour. "There was a definite correlation between toxicity and particle sizes of the inert materials, higher insecticidal efficiency being obtained with finer particles. It was found that insects dusted with effective inert materials lost weight very rapidly, which was assumed to be due mainly to the loss of water from the body. Respiration studies indicate that the inert material did not affect the oxygen consumption of the insect. It is thought that the inert materials killed the insects by desiccation."

[Contribution on the strawberry weevil *Anthonomus bisignifer* Schenkling], M. KARÔ (*Tôhoku Imp. Univ., Sci. Rpts.*, 4, ser., 12 (1938), No. 4, pp. 501-510, figs. 2; pp. 511-530, figs. 4).—Two further papers (E. S. R., 78, p. 226) are presented: The Temperature Limit of Activity of the Strawberry Weevil *Anthonomus bisignifer* Schenkling (pp. 501-510), including a list of 18 references to the literature, and The Diurnal Activity of the Strawberry Weevil *Anthonomus bisignifer* Schenkling, With a Note on the Ecological Meaning of the Solar Radiant Energy (pp. 511-530).

Studies of control measures for sweetpotato weevil in Louisiana. H. L. DOZIER (*Jour. Econ. Ent.*, 32 (1939), No. 2, pp. 313-318, figs. 2).

[Work in apiculture by the Wyoming Station] (*Wyoming Sta. Rpt. 1938*, pp. 18-21).—The work of the year, which again relates to wintering bees, two-queen colonies, and breeding for resistance to American foulbrood, is briefly considered in this report (E. S. R., 79, p. 83).

Recent investigations into bee-keeping at Rothamsted, D. M. T. MOBLAND (*Jour. Roy. Soc. Arts*, 86 (1938), No. 4451, pp. 394-402, figs. 6).—A summary of recent work in apiculture at the Rothamsted Experimental Station.

Importance of controlled mating of queens in the development of high producing strains of honeybees, R. S. FILMER. (N. J. Expt. Stas.). (*Jour. Econ. Ent.*, 32 (1939), No. 2, pp. 223-225).—The experiments reported indicate a decided and consistent increase in honey production in favor of the controlled mated queens and indicate the need for drone selection in the further development of our present strains of bees.

Bees and red clover, M. [H.] HAYDAK. (Minn. Expt. Sta.). (*Amer. Bee Jour.*, 78 (1938), No. 7, p. 313, fig. 1).—General information on the value of bees in red clover pollination, with reference to a new variety of clover with short corolla tubes.

Pollen stores and newly emerged bees, M. H. HAYDAK. (Minn. Expt. Sta.). (*Gleanings Bee Cult.*, 66 (1938), No. 5, p. 297).—This is a popular account of an experiment on the influence of a pure carbohydrate diet on newly emerged bees.

Photopsoid mutillids collected by Dr. K. A. Salman at Eagle Lake, California (Hymenoptera), C. E. MICKEL. (Minn. Expt. Sta.). (*Pan-Pacific Ent.*, 14 (1938), No. 4, pp. 178-185).

The yellow-headed spruce sawfly in Maine, R. W. NASH (*Jour. Econ. Ent.*, 32 (1939), No. 2, pp. 330-334, fig. 1).—The yellow-headed spruce sawfly was first noticed in Readfield, near Augusta, in early July 1934, feeding in a plantation of Norway spruce (*Picea excelsa*). It is now found well over the State and in places abundantly. It is considered under the headings of distribution, synonymy, description, life history, comparison with the European spruce sawfly, parasites, and control on ornamental spruce and in forest growth.

Spraying trials against red spider mite (*Oligonychus ulmi*) on damsons in Westmorland, R. A. HARPER GRAY (*Jour. Roy. Hort. Soc.*, 63 (1938), No. 2, pp. 77-80, pls. 2).—In the experiments reported summer spraying gave more efficient control of the European red mite than did winter spraying. Of the winter washes a tar oil and petroleum oil emulsified gave the best results. Efficient control was obtained by a summer wash consisting of refined white oil emulsion, and others, noticeably a lime-sulfur wash, gave good control.

Ticks as vectors of animal diseases, C. B. PHILIP (*Canad. Ent.*, 71 (1939), No. 3, pp. 55-65).—Information on the tick-borne diseases of animals in North America, South America, Europe, Africa, and Asia, and the ticks transmitting spirochaetes of relapsing fever is summarized, the details being given in table form.

ANIMAL PRODUCTION

[Experiments with livestock in Kentucky] (*Kentucky Sta. Rpt. 1938*, pt. 1, pp. 8-13, 39, 55, 56).—Results are briefly reported on the use of alfalfa-molasses silage for fattening steers; a comparison of distillers' corn dried grains v. cottonseed meal for fattening steers and heifers and for wintering beef cows; continuous v. rotational grazing of bluegrass pastures with ewes and lambs and with dairy heifers; lespedeza hay v. alfalfa for bred ewes; the gains secured by full feeding pigs on oat and rape, bluegrass, alfalfa, and lespedeza pastures; the relation of humidity during incubation to hatchability of turkey eggs; manganese required for normal hatching of turkey eggs and for normal growth of poults;

breeding chickens for longevity and high lifetime production; and a comparison of free-choice v. all-mash feeding of chickens.

[Livestock investigations in Wisconsin] (*Wisconsin Sta. Bul.* 443 (1939), pp. 82-91, fig. 1).—Studies for which results are reported include the value of molasses-alfalfa silage (made from good alfalfa) in the ration of milking cows, by G. Bohstedt, L. W. Rupel, and W. A. King; minerals required by pigs on soybean oil meal rations, by Bohstedt, J. M. Fargo, and King; the influence of "flushing" ewes on rate of ovulation and subsequent rate of lambing, by A. E. Darlow and L. E. Casida; the value of wheat germ oil when used as a supplement to a good poultry ration, and the interrelationships of manganese and phosphorus in the slipped tendon disease of chicks, both by J. G. Halpin, C. E. Holmes, and W. W. Cravens; the vitamin requirements of mature hens, by Halpin and Holmes; the effect of sulfur supplements in the diet on the production and hatchability of eggs, by Halpin, Holmes, and C. A. Herrick; the comparative vitamin D requirements of different breeds of chickens, by Halpin, Holmes, and E. B. Hart; the value of infertile eggs discarded by hatcheries in chick rations, by Halpin, Holmes, and M. H. Meshew; and the protein requirements of capons, and improved rations for growing poults, both by Halpin, G. E. Annin, and Holmes.

[Livestock investigations in Wyoming] (*Wyoming Sta. Rpt.* 1938, pp. 11, 12, 13-15, 16, 17, 26, 27, 30, 34, 38, 39, 40, 41).—Investigations at the main and substations, for which results are briefly reported, include the value of bonemeal as a supplement for range cattle; the effect of a low phosphorus ration and no sunshine on beef heifers; a comparison of various rations containing beet by-products for fattening steers; the relative rate and efficiency of gain of steers and bred, open, and spayed heifers; the wool- and mutton-producing qualities of crossbred lambs resulting from mating Rambouillet ewes with Lincoln, Romney, Corriedale, and Columbia rams; shrinkage in Wyoming wool; cottonseed cake as a supplement for range lambs pastured on low-yielding corn; comparison of various maintenance and fattening rations for range lambs; comparison of alfalfa pasture v. dry lot for fattening pigs on corn and tankage; composition of certain native forage plants; a comparison of methods of feeding grain to laying hens; the effect of varying periods of artificial illumination for laying hens; the isolation of a laxative principle in rye; the inheritance of resistance to coryza; elimination of crooked breastbones in turkeys by proper adjustment of roots; a comparison of vitamin A supplements for laying hens; and the relative cost of raising pullets by different methods.

Bilateral variation in the weight and composition of the long bones of some experimental animals, C. E. WEAKLEY, JR., and R. B. DUSTMAN. (W. Va. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 58 (1939), No. 9, pp. 711-716).—A study was made of the bilateral variation in the weight and composition of the green bones of 20 rats, 20 chicks, 19 hogs, and 2 dairy heifers. No significant differences were found between the right and left sides of the rat. In chicks the green weight and moisture content was slightly higher on the left side, while the percentage of ash and organic nonfat was slightly higher on the right side. This same condition prevailed in hogs, except that organic nonfat was higher in the left side than in the right. The dairy heifers showed a tendency toward heavier bones on the right side. In animals where one side tended toward a dominance in weight of bones, the same side tended to have a higher moisture content and the other side a higher ash content of bones.

Seasonal variation in the composition of bluebunch fescue, R. McCALL. (Wash. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 58 (1939), No. 8, pp. 603-616).—Samples of bluebunch fescue collected at semimonthly intervals over a 4-yr. period (1930-34) were analyzed. Seasonal variation in composition showed somewhat different trends during the different years, depending on prevailing

moisture and temperature conditions. Stage of maturity was the most important single factor affecting seasonal composition, particularly with reference to crude protein content, which ranged from 25.55 percent in young, growing grass to 4.56 percent in mature samples. Crude fat was highest in the new growth but variable thereafter, while ash, nitrogen-free extract, and crude fiber tended to increase as the plant approached maturity. Calcium and phosphorus contents were highest in young grass, while the rate of decline with advancing maturity was considerably faster for the latter. Both elements were so low* in winter grass as to suggest the need of mineral supplement when the winter ration of animals was largely limited to the dry mature grass.

Monthly variation in carotene content of two important range grasses, *Sporobolus flexuosus* and *Bouteloua eriopoda*, W. E. WATKINS. (N. Mex. Expt. Sta.). (*Jour. Agr. Res. [U. S.], 58 (1939), No. 9, pp. 695-699, fig. 1*).—Samples of two important range grasses, mesa dropseed and black grama, collected at monthly intervals from protected enclosures on a southern New Mexico range were analyzed for carotene content. Both grasses were found to be moderately high in carotene during the growing season, reaching a peak in September. After this date, the mesa dropseed declined sharply and became entirely devoid of carotene soon after the end of the growing season. The black grama, which has a certain amount of green stem throughout the winter, contained from 4 to 11 percent as much carotene during the winter as during the early growing season. This level in midwinter seemed adequate to meet the requirements of range cattle for vitamin A.

Haying in the rain: A study of grass silage, J. G. ARCHIBALD and C. H. PARSONS (*Massachusetts Sta. Bul. 362 (1939), pp. 19, pls. 4*).—The results of 3 years' study on the preparation and feeding of grass silage are reported. Any of the annual or perennial grasses or legumes or the small grains proved suitable for ensiling provided they were cut at the proper stage of maturity. A moisture content of from 60 to 75 percent at the time of ensiling is recommended, and very succulent material should be wilted in the swath until this moisture level is attained. Additions of 40, 60, and from 75 to 80 lb. of molasses per ton of green material is recommended for the grasses or small grains, grass-clover mixtures, and straight legumes, respectively. Practical suggestions for feeding grass silage are offered. Feeding trials indicated that grass silage was equal to corn silage and superior to cured hay for milk production. Milk produced on the grass silage ration was higher in vitamin A and better in flavor than milk produced on the dry hay ration. The cost per unit of dry matter was similar for the grass silage and cured hay.

Grass silage: Its place in agriculture, C. B. BENDER and E. S. SAVAGE (*New Jersey Sta. Cir. 386 (1939), pp. 16, figs. 3*).—A practical discussion of the place of grass silage in the agricultural program, crops adaptable for the production of silage, various steps in the harvesting and ensiling of grass crops including kinds and amounts of preservatives to use, and ways of incorporating grass silage into the livestock feeding program.

Nutritive value and chemical composition of certain fresh-water plants of Minnesota, I-III (*Minnesota Sta. Tech. Bul. 136 (1939), pp. 47, pls. 3, figs. 4*).—The results of three separate studies are reported in this publication.

I. Nutritive value and general chemical composition of species of *Elodea*, *Myriophyllum*, *Vallisneria*, and other aquatic plants, J. W. Nelson and L. S. Palmer (pp. 4-34).—Proximate analyses of the above species indicated an average ash content of 21.87, 13.83, and 15.64 percent, crude protein of 26.81, 25.83, and 15.15, and crude fiber of 15.39, 14.13, and 15.82 percent in the dry matter of *Elodea*, *Myriophyllum*, and *Vallisneria*, respectively. Mineral analyses indicated that the ash was well balanced from a nutritional standpoint,

with the possible exception of an inadequate supply of phosphorus, sodium, and chlorine. All three species were relatively rich sources of carotene and vitamins B, C, and G, but all were practically devoid of vitamins D and E. The plants differed widely in quality of protein, having coefficients of apparent digestibility of 70.28, 27.44, and 28.6, with biological values of protein of 42.71, 0, and 0, respectively. There was no evidence of any toxicity connected with these plants in rat feeding tests.

II. *The nitrogen distribution of *Blodea canadensis**, A. N. Wick and W. M. Sandstrom (pp. 33-42).—This high-nitrogen species (over 4 percent nitrogen in an oven-dried sample) was further analyzed with reference to nitrogen distribution. Over one-half of the water-soluble nitrogen was isolated as a protein, while about one-third appeared in simpler compounds such as ammonia, amides, amino acids, and polypeptides. Two proteins, one water-soluble and the other alkali-soluble, were isolated. However, repeated efforts to prepare these proteins ash-free resulted in failure.

III. *The nature of the carbohydrates of species of *Blodea*, *Myriophyllum*, *Ceratophyllum*, *Ruppia*, and *Ranunculus**, H. V. Lindstrom and W. M. Sandstrom (pp. 43-47).—The above five species were analyzed for certain carbohydrate constituents. In all cases these species were lower in sugar but generally higher in starch than the common cultivated hays. These aquatic species were all relatively low in crude fiber, which consisted almost wholly of cellulose. The uronic acids present largely accounted for the pentose-yielding materials in these plants.

The growth, activity, and composition of rats fed diets balanced and unbalanced with respect to protein, T. S. HAMILTON. (Univ. Ill.). (*Jour. Nutr.*, 17 (1939), No. 6, pp. 565-582).—The effect of varying the protein level in an otherwise complete diet from 4 to 54 percent (by substituting whole egg protein for cornstarch) was studied in a series of paired rat feeding experiments. Feeding at 10 different protein levels, it was found that as protein increased (1) metabolizable energy increased very slowly, (2) the percentage of gross energy which was metabolized was unchanged until the 30-percent level was reached, while above this level a gradual decrease occurred, (3) a gradual decrease in the ratio of energy to nitrogen in the urine occurred, and (4) no consistent effect upon digestibility of either food energy or food nitrogen could be noted. Optimum growth occurred when the protein level ranged from 16 to 30 percent. Total gain in weight was not as good a criterion of growth as gain in protein and gain in body length. The composition of gains was markedly affected by the extremes of protein feeding, but little affected within the range of 16 to 42 percent.

The heat increments of diets balanced and unbalanced with respect to protein, T. S. HAMILTON. (Univ. Ill.). (*Jour. Nutr.*, 17 (1939), No. 6, pp. 583-599).—Further data from the above trials indicated that the heat increment of the diet decreased coincident with increases in percentage of protein up to about the 18-percent level, remained constant within a range of 18 to 30 percent, and then increased again as the protein increased to 42 percent or above. A close inverse relationship was found to exist between the heat increments and the growth-promoting abilities of the rations, with maximum net energy values for growth and maintenance occurring within the 16 to 30 percent protein range. The percentage of net energy used for basal expenditures or for voluntary activity was unaffected by the protein level.

The heat production and blood and urine constituents after administration of d-lysine monohydrochloride to the dog, J. R. Dorr and A. G. Eaton. (La. State Univ.). (*Jour. Nutr.*, 17 (1939), No. 5, pp. 497-504).—Dogs

thoroughly trained for metabolic experiments and with established basal metabolic rates received injections of glycine (check) or lysine. Blood and urine analyses indicated that lysine is metabolized much more slowly than glycine and is readily excreted by the kidneys if present in the blood in large quantities. Lysine did not produce a specific dynamic action, as indicated by the heat production after its injection.

The heat production and blood and urine constituents after administration of d-arginine monohydrochloride to the dog, A. G. EATON and J. R. DORY. (La. State Univ.). (*Jour. Nutr.*, 17 (1939), No. 5, pp. 505-511).—In experiments similar to the above, arginine was administered to dogs either intravenously or orally. Following either type of administration a prompt and sustained rise in the urea nitrogen of the blood was noted, and in the intravenous injection a considerable proportion was excreted in the urine as unchanged arginine. Arginine was metabolized somewhat more slowly than glycine, and on the basis of Calories per unit deaminized it had a slightly higher dynamic action than glycine.

Vitamins in the nutrition of animals, W. C. RUSSELL. (N. J. Expt. Stas.). (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 2, pp. 81-89).—A summary.

The influence of exercise on the growing rat in the presence and absence of vitamin A, N. B. GUERRANT, R. A. DUTCHER, and F. CHORNOCK. (Pa. Expt. Sta.). (*Jour. Nutr.*, 17 (1939), No. 5, pp. 473-484, figs. 5).—Three groups of young rats on a vitamin A-deficient basal diet until depleted and then given vitamin A supplement and comparable groups constantly fed a vitamin A-adequate diet were subjected to forced exercise, voluntary exercise, and to confinement in the usual type of cage, respectively. Under comparable conditions of feeding less food was consumed, less gain in weight was made, and less severe symptoms of vitamin A deficiency developed when animals were forced to exercise than under voluntary exercise or confinement. Forced exercise resulted in the greatest efficiency of food utilization but also in the voiding of the greatest number of fecal pellets. Under voluntary exercise conditions, animals receiving adequate vitamin A were more active physically than those on the vitamin-A deficient diet.

Vitamin E and nutritional muscular dystrophy, C. G. MACKENZIE and E. V. MCCOLLUM (*Science*, 89 (1939), No. 2312, pp. 370, 371).—Preliminary findings gave evidence that the type of muscular dystrophy which develops in rabbits confined to the Goettsch and Pappenheimer basal diet No. 13 (E. S. R., 66, p. 796) can be promptly cured by the administration of small doses of vitamin E concentrate or by the administration of natural alpha tocopherol.

The vitamin G content of some oil press-cake meals and related products, F. W. SHERWOOD and J. O. HALVERSON. (N. C. Expt. Sta.). (*Jour. Agr. Res.* [U. S.], 58 (1939), No. 10, pp. 787-794, fig. 1).—Employing the rat-growth method of assay and considering vitamin G as the undifferentiated complex which stimulates growth when the basal ration is supplied with an extract of rice polish but otherwise free of water-soluble vitamins, the vitamin G content of 4 samples of peanut meal, 6 of cottonseed meal, 1 of cottonseed flour, 1 of cottonseed hull bran, 3 of linseed meal, 5 of soybean meal, and 1 of soybeans was found to range between 2.5 and 5.9 Sherman-Bourquin units per gram (E. S. R., 79, p. 669).

Determination of slaughter-steer grades from weights and measurements, B. KNAPP, JR. (U. S. Dept. Agr. Cir. 524 (1939), pp. 8, figs. 4).—Based on the data secured on 167 steers of Hereford, Shorthorn, Aberdeen Angus, and dairy breeding, the following formula was derived which expresses the multiple curvilinear relationship between height at withers, weight or heart girth,

and slaughter grade: Grade = $-223.2839 - 3.5853 (H) + 157.9825 (\log W)$, in which grade is the slaughter grade in percent, (H) is the height at withers in inches, and ($\log W$) is the log of live weight in pounds. The greatest deviation between the grade assigned by trained graders and the predicted grade by this formula was one-half of a grade. A table is presented showing slaughter-grade classification on the basis of height at withers and heart girth which may be used when scales are not available.

Hybrid baby beef production, F. C. DAUGHERTY (*North Dakota Sta. Bimo. Bul.*, 1 (1939), No. 5, p. 10).—A brief progress report on the birth weight and rate of gain of calves resulting from reciprocal crosses of Aberdeen Angus and Shorthorn cattle as compared with purebred calves of each breed.

Relationship between carotene, blindness due to constriction of the optic nerve, papillary edema, and nyctalopia in calves, L. A. MOORE. (Mich. Expt. Sta.). (*Jour. Nutr.*, 17 (1939), No. 5, pp. 443-459, figs. 7).—Following a previous report (E. S. R., 73, p. 672), conclusive evidence has been secured to indicate that calves fed low carotene rations developed night blindness, papillary edema, and a permanent type of blindness associated with a constriction of the optic nerve. The development of these conditions was prevented by supplementing the low carotene ration with crystalline carotene dissolved in cottonseed oil, indicating that these conditions are a part of the syndrome of vitamin A deficiency in calves. Other conditions associated with these abnormalities are described. Vitamin A deficiency in calves may be diagnosed by the presence of both papillary edema and night blindness, and, under proper conditions of observation, by bleaching of the tapetum lucidum of the retina. Plasma carotene determinations of the bovine also give an indication of the vitamin A reserve under conditions of low carotene intake.

Improving beef cattle pastures on rice lands, C. I. BRAY (*Louisiana Sta. Bul.* 305 (1939), pp. 14, figs. 4).—Grazing trials with beef cattle during three seasons gave evidence that on rice fallow land, where rice alternated with pastures every other year, the grazing was profitably increased by seeding with white clover, lespedeza, or Italian ryegrass. Seeding directly on the rice stubble with little or no seedbed preparation is considered most practical. The merits of more permanent pasture to be grazed 2 yr. or more is discussed, and suggestions for establishing such pastures are offered.

Reducing the corn and increasing the hay content of rations for fattening yearling steers.—Summary of three years, P. GERLAUGH and C. W. GAY (*Ohio Sta. Bimo. Bul.* 198 (1939), pp. 57-60).—A summary of the results of three trials showed an average daily gain per steer of 1.91, 1.78, and 1.69 lb. for groups of steers receiving a full grain ration, three-fourths full feed, and one-half full feed, respectively. The average selling price of cattle in the second group was only slightly lower than for the full-fed cattle, whereas those in the third group sold for about 80 ct. per hundredweight less than the full-fed steers. On the basis of average yields of corn and hay the ratio of acres of corn (grain and silage) to acres of hay consumed under the three plans were 5.5:1, 2.3:1, and 1.2:1, respectively. The second plan is considered a sound farm practice under average conditions, while the third plan is not recommended unless hay is very low in price.

Reducing the amount of corn and increasing the amount of legume hay in rations for fattening yearling steers, III, P. GERLAUGH and C. W. GAY (*Ohio Sta. Bimo. Bul.* 198 (1939), pp. 55, 56).—The third trial in this series (E. S. R., 79, p. 670) was conducted under the same general plan as earlier trials. The results tended to substantiate the previous findings.

Fattening steer calves—varying the amounts of supplement and molasses, P. GERLAUGH (*Ohio Sta. Bimo. Bul.* 198 (1939), pp. 53-55).—Following ear-

her studies to determine the optimum level of protein supplement in steer fattening rations (E. S. R., 79, p. 670), five lots of steers receiving a basal ration of shelled corn, silage, and mixed hay were given varying amounts of mixed protein supplement with and without additions of molasses. The addition of 1 lb. of molasses per steer daily to the check ration (1.5 lb. protein supplement per steer daily) increased the rate of gain of steers and the final degree of finish and appeared to be justified at prevailing feed prices. Further increase in either the amount of molasses or of protein supplement increased the feed cost more than the increased rate of gain would justify.

Returns per acre in cattle feeding: Medium and late varieties of corn for silage; silage versus limited amounts of corn-and-cob meal, P. GERRAUGH and H. W. ROGERS (Ohio Sta. Bimo. Bul. 198 (1939), pp. 60, 61).—This trial was designed to determine the returns per acre of corn in terms of beef when each of two varieties of corn was fed as silage and one of the varieties was fed as corn-and-cob meal plus stover. A mixed protein concentrate and legume hay supplemented the corn products in each instance. The average daily gain of steers was practically identical for the three groups of cattle. The dry-fed cattle showed slightly better finish at the conclusion of the test, but the pounds of gain per acre of corn and hay were favorable to the silage-fed lots.

Oat hay poisoning, W. B. BRADLEY, O. A. BEATH, and H. F. EPPSON. (Univ. Wyo.). (Science, 89 (1939), No. 2312, p. 365).—Confirmatory evidence was secured to indicate that oat hay produced in certain areas of Wyoming exerted a strongly toxic effect on cattle. Eleven lb. of this toxic hay caused the death of a 350-lb. steer 9 hr. after feeding, while the water extract of 11 lb. of the hay caused typical symptoms in another steer of similar size. In each instance a high methemoglobin content of the red blood cells was observed. Preliminary investigations indicate that the toxicant is formed during the development of the oat plant. The localization of the problem suggests the basic significance of local influences.

A ranch observation on feeding sheaf oats to lambing ewes, L. R. VAWTER. (Nev. Expt. Sta.). (Jour. Amer. Vet. Med. Assoc., 94 (1939), No. 2, pp. 128, 129).—In the incident reported, a flock of pregnant ewes was confined in pens and subsisted entirely on a diet of sheaf oats from late December to March. About 15 percent of the ewes died soon after lambing with a symptom complex suggesting pregnancy disease or vitamin A and calcium deficiency. The losses stopped abruptly when the flock was removed to a larger, clean pen and fed good alfalfa hay in addition to the sheaf oats, suggesting that the oat plant was inadequate when fed as a sole diet to the ewe breeding flock.

The relation between the down hair and curl on the Karakul lamb and the mature Karakul sheep [trans. title], L. ADAMETZ (Ztschr. Tierzücht. u. Züchtungsbiol., 41 (1938), No. 1, pp. 90-106).—A study of 10 Karakul fleece and lamb skins grading from good to prime led to the belief that the amount and tightness of curl depended on several properties in addition to fineness of down and prevalence of guard hairs.

The role of riboflavin and other factors of the vitamin-B complex in the nutrition of the pig, E. H. HUGHES. (Univ. Calif.). (Jour. Nutr., 17 (1939), No. 6, pp. 527-533, figs. 2).—Continuing this line of investigation (E. S. R., 80, p. 670), additional evidence was secured to indicate that riboflavin, thiamin, and one or both dietary factors present in rice bran filtrate are essential for the proper nutrition of the pig.

The value of fortified cod liver oil in the production of market hogs, W. C. SKELLEY (New Jersey Stat. Bul. 661 (1939), pp. 15, figs. 2).—In a trial involving eight lots of five Duroc-Jersey pigs each (initial weight about 41 lb.),

all lots were kept indoors without exposure to sunshine and fed a ration of corn meal, tankage, and minerals. One-half of the lots received a supplement to the basal ration of 0.25 percent of fortified cod-liver oil. Over an experimental period of 128 days the average daily gains per pig were 1.019 and 1.219 lb., and the feed required per 100 lb. of gain 456.7 and 364.8 lb. for the control and supplemented groups, respectively. Three lots carried for 165 days showed similar trends in rate and efficiency of gain. Slaughter tests failed to show any marked differences in dressing percentages of the various groups, and there was no evidence of off-flavor or odor in the carcasses as a result of feeding the fortified cod-liver oil. Pigs in the supplemented groups showed a slightly higher percentage of bone ash, but there was no significant difference in levels of calcium and phosphorus in the blood of pigs in the various groups. However, two pigs from the control groups which died after 87 and 126 days on experiment showed typical rachitic symptoms.

Spelt equals oats for pigs, V. A. FREEMAN (*Michigan Sta. Quart. Bul.*, 21 (1939), No. 4, pp. 279, 280).—A single feeding trial in which spelt and oats were each fed in combination with corn and a protein supplement to fattening pigs indicated that these two grains were of very similar feeding value.

A study of bacteria contaminating sides for Wiltshire bacon, with special consideration of their behaviour in concentrated salt solutions, E. H. GARRARD and A. G. LOCHHEAD (*Canad. Jour. Res.*, 17 (1939), No. 2, Sect. D, pp. 45-58, figs. 3).—Forty microbial types (micrococci predominating) were isolated from sides of bacon prior to curing and considered representative of precuring contamination. These have been classified into five groups, depending on their ability to survive in salt solution and curing pickle. The organisms displayed much greater resistance to salt in curing pickle than in brine of similar sodium chloride content, indicating that the pickle exerted a protective action against the toxic effect of salt. Many types survived the pickling, leading to the suggestion that those types may later become active and contribute to storage defects. Nitrate reduction in curing pickle appeared to be a function of true halophiles rather than to any of the precuring contaminants.

Principles of poultry breeding, F. B. HUNT. (Cornell Univ.). (*U. S. Egg and Poultry Mag.*, 45 (1939), No. 6, pp. 364, 365).—A brief résumé.

Nutritional gizzard lesions in chicks, W. B. ESSELEN, JR. (*Massachusetts Sta. Bul.* 355 (1939), pp. 73, 74, pl. 1).—A progress report.

Distribution of phosphorus in the leg bones of chickens, M. J. L. DOLS, B. C. P. JANSSEN, G. J. SIZOO, and G. J. VAN DER MAAS (*Nature [London]*, 142 (1938), No. 3604, pp. 953, 954, fig. 1).—Solutions of radioactive phosphorus were intraperitoneally injected into both rachitic and normal chicks, and the distribution of phosphorus in the leg bones was studied 22 hr. after injection. As expected, the phosphorus content of the dry matter in all parts of the bones of normal chicks was higher than in rachitic chicks. In both lots the total phosphorus content of the diaphysial part of the bone was higher than for the epiphysial part of the same bone. A greater concentration of the radioactive phosphorus was found in the bones of rachitic chicks than in normal ones, also a greater concentration in the epiphysial part than the diaphysial part of the same bone, thus indicating that phosphorus metabolism is more intense in the bones of rachitic chicks than in the bones of normal ones and also more intense in the epiphysial part than in the diaphysial part of the same bone.

The need for manganese in the bone development of the chick, C. D. CASKEY, W. D. GALLUP, and L. C. NORRIS. (Cornell Univ.). (*Jour. Nutr.*, 1st (1939), No. 5, pp. 407-417, fig. 1).—This is a more detailed report of the research previously noted (*El. S. R.*, 79, p. 235).

Some observations on methods of fattening chickens, A. J. G. and W. A. MAW (*U. S. Egg and Poultry Mag.*, 45 (1939), No. 6, pp. 332-334, 378, figs. 2).—The results of two trials at Macdonald College comparing the rate and efficiency of gain of Rhode Island Red cockerels over fattening periods of 7, 10, 14, and 21 days when fed two, three, and five times per day are presented. Two feeds per day gave definitely smaller average gains than three or five feeds and also the groups getting the larger number of feeds per day showed a slight advantage in gain per unit of feed consumed. There was a high variability in amount of daily gain by individuals which is at least partially attributed to various uncontrolled environmental factors.

Canadian studies on electrical methods of killing poultry, D. C. ROSE (*U. S. Egg and Poultry Mag.*, 45 (1939), No. 5, pp. 270-275, figs. 7).—The results of preliminary studies at the Canadian National Research Laboratories on the applicability of electrical methods for killing poultry are reported. The electrical circuits and types of electrodes used in these studies are illustrated. By a proper regulation of voltage and resistance in the circuit and proper application of the electrodes good feather release could be obtained, and the bleeding after electrical stunning was satisfactory.

The feed cost of producing eggs in New Jersey in 1938, L. M. BLACK (*New Jersey Sta. Hints to Poultrymen*, 26 (1938), No. 1, pp. 4).—A summary of 14 individual flock records showed an average annual egg production of 181.2 and 136 eggs per pullet and per hen, respectively, an average total feed consumption of 95.3 lb. per bird, and an average return above feed costs of \$2.13 per bird, based on the average number of birds for the year. The percentage decrease in number of birds during the year was 48.8 and 45.7 for pullets and hens, respectively.

Millet feeding for turkeys, G. P. GOODEARL (*North Dakota Sta. Bmo. Bul.*, 1 (1939), No. 5, pp. 3-6).—Three years' experiments in which proso millet replaced one-half or all of the yellow corn in standard starting and growing rations for turkeys gave evidence that the millet rations were readily consumed by young, growing turkeys. The millet-fed groups consistently weighed more at marketing time than the corn-fed group, while on the average slightly more millet rations were consumed per pound of gain. There was little difference in the rate of mortality in the various groups.

Relative influence of the various factors that affect egg production of turkeys during different parts of the first laying year, V. S. ASMUNDSON. (Calif. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 58 (1939), No. 10, pp. 747-754).—In further analyzing the data previously described (E. S. R., 79, p. 381), the first laying-year records of turkey hens were arbitrarily divided into three periods: (1) From first egg to end of April, (2) May and June, and (3) after June. Egg production in each period was correlated with various factors. Egg production during the first period was influenced most by sexual maturity (date of first egg) and to a lesser extent in order by length of pauses, date of last egg, and net rate. Egg production in May and June was influenced most by length of pauses and date of last egg, while persistency was by far the greatest influence after June. Factors of greatest importance in selecting for improved egg production during the breeding season are, in order of importance, sexual maturity, length and number of all broody and nonbroody pauses, and net spring rate.

Finishing rations for turkeys, E. I. ROBERTSON, J. S. CARYER, and J. W. COOK (*Washington Sta. Bul.* 372 (1939), pp. 20, fig. 1).—In the experiments described, six pens of poults were raised to 20 weeks of age on the same starting and developing rations, the one variation in treatment consisting of different methods of feeding grain. At 20 weeks of age there were only slight differences

in the weight of groups receiving only the pelleted mash ration, those receiving pellets plus grain (hand-fed), and those receiving pellets plus grain (hopper-fed). The poults were redistributed into six groups at 20 weeks and fed over an 8-week experimental period to compare three finishing rations and two grain mixtures. Approximately 48 percent of the total feed was consumed during this 2-mo. period. There was little difference between the weight of hens or toms in the various groups, the toms averaging 25.9 lb. and the hens 15.9 lb. at 28 weeks. All of the rations gave good results in growth, feathering, and fleshing, and the average returns per turkey over feed costs were very similar, ranging from \$2.19 to \$2.35. The hens showed approximately 2 weeks' earlier feathering and fleshing than the toms. The shrinkage between live weight before killing and dressed weight was 9 percent after a 24-hr. starvation period on wire floors.

The proper handling of hatching eggs and the incubator on the farm, V. DARAGO (*New Jersey Stas. Hints to Poultrymen*, 26 (1939), No. 2, pp. 4).—Practical suggestions are offered.

DAIRY FARMING—DAIRYING

[Experiments with dairy cattle and dairy products in Massachusetts] (*Massachusetts Sta. Bul.* 355 (1939), pp. 22-24, 38, 45-51).—Progress reports (E. S. R., 79, p. 529) are presented for the following lines of investigation by J. G. Archibald, C. H. Parsons, W. S. Ritchie, and W. Esselen, Jr.: The effect of vitamin A concentrates on growth and reproduction in dairy cattle; the effect of complex mineral and vitamin mixtures on general health, reproduction, and milk production in dairy cattle; the influence of supplemental phosphorus in the ration on the phosphorus content of milk; the influence of artificial light on milk production; the composition and vitamin content of certain pasture grasses; the production and use of legume and grass silages; and the value of dried citrus pulp for dairy cattle.

Reports of studies with dairy products by W. S. Mueller, M. J. Mack, L. D. Lipman, R. L. France, H. G. Lindquist, J. H. Frandsen, and M. Glickstein include methods of improving flavor and keeping properties of milk and certain milk products; the effect of chocolate-flavored sirups on certain properties of chocolate milk; factors to be considered in selecting chocolate-flavored milk; the nutritive value of chocolate-flavored sirup containing yeast; the digestibility of chocolate-flavored milk in vitro; bacteriological properties of chocolate-flavored sirups and cocoas; the effect of aging treatments on gelatin and other ice cream stabilizers; factors affecting the properties of whipped cream; changes occurring in the storage of frozen sweet cream; egg solids as a constituent of ice creams; factors affecting the melting appearance of ice cream; sodium alginate as a stabilizer for ice cream; the stability of the fat emulsion of cream; the development of new dairy products utilizing milk, cream, cheese, and plastic cream; the utilization of whey byproducts; and the efficiency of a multiple-purpose separator.

[Experiments with dairy cattle in Wyoming] (*Wyoming Sta. Rpt.* 1938, pp. 12, 13, 28, 29).—Brief results are reported for the following investigations: The effect of maintaining heavy milking cows for long periods on a ration consisting solely of alfalfa hay and pasture; the economy of limited grain feeding v. sole roughage feeding for milking cows; open-shed v. stable milking; and roughage rations for dairy heifers.

Studies on the composition of bovine blood as influenced by gestation, lactation, and age, W. L. KENNEDY, A. K. ANDERSON, S. I. BECHDEL, and J. F. SHIGLEY. (Pa. Expt. Sta.). (*Jour. Dairy Sci.*, 22 (1939), No. 4, pp. 251-260,

figs. 3).—Analyses of blood samples collected at weekly intervals from dairy heifers throughout the period of gestation and 1 yr. of lactation showed comparatively little variation in the levels of nonprotein nitrogen, glucose, calcium, and phosphorus over this period. Average values obtained for nonprotein nitrogen were 32.82, for glucose 52.12, for calcium 10.91, and for phosphorus 5.44 mg. per 100 cc. of blood. Blood sugar studies on calves from birth to approximately 2 yr. of age indicated a marked effect of age on blood glucose levels, average values ranging from 125 mg. per 100 cc. of blood for calves under 1 week of age to 54.4 mg. at the end of the year. Carbohydrate tolerance tests on animals at different ages showed a marked response to sugar feeding in young calves, but very little response in the older groups.

The chemical composition of the blood of the dairy goat, O. B. HOUGHIN, W. R. GRAHAM, JR., V. E. PETERSON, and C. W. TURNER. (Mo. Expt. Sta.). (*Jour. Dairy Sci.*, 22 (1939), No. 4, pp. 241-250).—Data on the average values for the more important constituents of arterial and venous blood of dry and lactating goats, obtained during the course of previously reported experiments (E. S. R., 78, p. 689; 80, p. 534), are presented as tentative normal standards for this species, along with comparative data for other species. No significant differences in the composition of the goat plasma in comparison with other mammals were apparent. Cell volume for the goat appeared unusually low, probably due to the small size of the red blood corpuscles. Sixty-three references are cited.

A study of factors concerning herd management and herd production, L. COPELAND (*Jour. Dairy Sci.*, 22 (1939), No. 4, pp. 229-239, fig. 1).—A detailed analysis of the production records of 1,046 Jersey herds which had completed at least 1 yr. of official Herd Improvement Registry testing led to the following general conclusions: The percentage of dry cows in the herd during the year is one of the main factors affecting the herd production average, the average of all herds containing about 15 percent of dry cattle. Breeding efficiency, which largely determined the percentage of dry cows, is inversely related to the size of the herd. Culling is an advantageous practice, regardless of the herd average. Herd Improvement lactation records of from 10 to 12 months' duration averaged from 10 to 12 percent lower than comparable Register of Merit records. Jersey heifers freshened at an average age of 2 yr. 2.5 mo., while the average age of all producing cows was 5 yr. 2 mo. Persistency of lactation tended to decline slightly with advancing age. Three- and 4-year-old cows predominated in replacements, while over 54 percent of all cows removed from herds were under 5 yr. of age. First-calf heifers freshening during the year did not handicap the herd average.

Skim milk powder for calves and a comparison of various supplemental feeds, A. C. McCANDLEISH (*West of Scot. Agr. Col., Res. Bul. 7* (1939), pp. 64).—A summary of the available literature with 277 references is presented, together with the results of 12 experimental feeding trials involving a total of 74 calves. An average gain of 1.65 lb. per calf daily was obtained in a check group of calves receiving whole milk, grain, and hay to 90 days of age. Four grain mixtures each in combination with reconstituted skim milk were compared among the other lots. Relatively good gains were secured in all cases, although the bloom on the skim milk-fed calves was not as good as with the whole-milk group. No reactions to the tuberculin test occurred among the skim milk powder-fed groups. Where skim milk powder was fed with hay and a suitable grain mixture the question of protein quality did not arise.

Magnesium and vitamin D relationships in calves fed mineralized milk, C. E. KNOOP, W. E. KRAUSS, and C. C. HAYDEN. (Ohio Expt. Sta.). (*Jour.*

Dairy Sci., 22 (1939), No. 4, pp. 283-289, fig. 1).—Three groups of Holstein calves receiving a ration of (1) a basal diet of whole milk plus iron and copper, (2) basal plus magnesium carbonate, and (3) basal plus magnesium carbonate plus ultraviolet irradiation from birth to 255 days of age were compared with reference to rate of growth, blood picture, and quality of bones. The rate of gain was quite regular and similar for all groups to 140 days of age, while beyond this age the rate of gain decreased and became quite irregular in all cases. Blood studies indicated fairly constant and normal blood calcium values for all calves, although certain calves in both lots 1 and 2 had values sufficiently low to suggest low calcium rickets. The blood phosphorus values tended to decrease slightly in all cases as the experiment advanced. Blood magnesium values decreased steadily in the control group, reaching a level below 2 mg. when the calves were 120 days of age, while normal values were consistently maintained in lots 2 and 3. Bone magnesium values were quite similar in groups 2 and 3, both averaging consistently higher than group 1. Calves receiving ultraviolet irradiation had heavier bones than the other groups, but otherwise little difference was noted between the three groups.

The influence of different levels of fat in the ration upon milk and fat secretion, G. GIBSON and C. F. HUFFMAN (*Michigan Sta. Quart. Bul.*, 21 (1939), No. 4, pp. 258-264, figs. 2).—Two groups of milking cows were fed rations of varying fat contents over 24-day experimental periods. The basal low-fat ration was composed of alfalfa, molasses, dried beet pulp, solvent-extracted soybean oil meal, and bonemeal. The addition of soybean oil in place of an isodynamic amount of beet pulp to this basal ration resulted in an increase in milk production and caused a temporary sharp increase in percentage of butterfat in the milk. However, within a short time (4-12 days) the fat percentage returned to normal. Replacing beet pulp by corn in the basal ration resulted in an increase in milk production, while the fat content of the milk remained unchanged. When a high-fat ration (basal plus soybean oil) was replaced by one low in fat, there was a drop in milk production but an increase in the percentage of fat in the milk. Thus it appeared that the basal ration was the important factor in determining the effect of the addition of fat to the ration on milk and fat secretion.

Composition and properties of goat's milk as compared with cow's milk, J. A. GAMBLE, N. R. ELLIS, and A. K. BESLEY (*U. S. Dept. Agr., Tech. Bul.* 671 (1939), pp. 72, figs. 11).—The results of a detailed study carried on from 1929 to 1932 and comparing the milk of 20 to 25 Saanen and Toggenburg does with Holstein and Jersey cow's milk are reported. The goat's milk on the average was similar to Holstein milk in percentages of water, protein, fat, and lactose, although subject to greater variation with advance of lactation than either of the cow's milk. It contained a high ratio of albumin and globulin to casein and considerably higher quantities of the fatty acids, caproic, caprylic, and capric, than did either of the cow's milk. The fat globules of Holstein milk averaged 1.97 times and Jersey milk 5.53 times as large as those of goat's milk, while the curd of the latter was 31 and 54 percent softer than that of Holstein and Jersey milk, respectively. There was no significant difference in surface tension measurements of the three milks. The buffer capacities of goat's milk and Jersey milk were similar over a pH range of 5.2 to 6.4, both exceeding Holstein milk in this respect. The vitamin content of the milks as determined by tests with rats and guinea pigs showed goat's milk to be similar to Holstein milk in vitamin A content, relatively high in vitamins B and G potency, and entirely lacking in vitamin E. The milks were all similar in vitamin D potency, while all were inadequate sources of vitamin C in the levels consumed. All three milks were low in iron, and nutritional anemia developed on any of the unsupplemented milk

diets. Aseptically drawn goat's milk was generally very low in bacteria, over 60 percent of the samples showing no evidence of bacterial growth. Controlled feeding tests with rats, goat kids, and healthy babies failed to show any significant differences in growth-promoting properties of any of the milks, gains occurring in each instance in proportion to the total nutrients consumed in the milk. A bibliography of 136 references is appended.

Effect of heat on milk, with especial reference to the cooked flavor, I. A. GOULD, JR., and H. H. SOMMER (*Michigan Sta. Tech. Bul.* 164 (1939), pp. 48, figs. 6).—The major objectives of this study were to determine the temperature at which cooked flavor may be produced in whole milk, cream, and skim milk; the influence of various factors upon the temperature at which cooked flavors are produced; the relation between the temperature causing cooked flavor and that which prevents oxidized flavor development; and the relationship between cooked flavor and the liberation of sulfides from milk. The appearance of cooked flavor proved to be a function of time as well as temperature, such flavors occurring when milk was heated to 76°–78° C. momentarily, 74°–76° for 3 min., or 70°–72° for 30 min. Increasing the pH of milk and increasing the butterfat content each caused a lowering of the cooked flavor temperature, while skim milk required 2°–4° higher temperature to produce this flavor defect than whole milk. Aeration of the milk during heating, dilution with water, separation and remixing, and mastitis infection, all had little influence on cooked flavor. Temperature and breed differences in this respect were slight. The oxidation-reduction potential of milk, skim milk, or cream showed no change until the temperature was sufficiently high to produce cooked flavor, but above this point the Eh became progressively more negative with increase in temperatures. The cooked flavor was found closely related to heat prevention of oxidized flavor if copper contamination occurred before heating, but no relation was observed when copper was added after heating. The cooked flavor is attributed to the formation of sulfides which occur when milk is subjected to sufficiently high temperatures or to other changes occurring simultaneously with this formation.

The effect of churning on the vitamin A and carotene content of milk fat, K. M. HENRY, S. K. KON, A. E. GILLAM, and P. WHITE (*Jour. Dairy Res.* [London], 10 (1939), No. 1, pp. 114–117).—A comparison of vitamin A and the carotene content of 14 samples of churned butterfat with comparable ether-extracted fat samples from the same milks indicated that a significant amount of carotene was lost in churning, while the vitamin A content was not appreciably affected.

Ascorbic acid and oxidized flavor in milk.—I, Distribution of ascorbic acid and occurrence of oxidized flavor in commercial grade A raw, in pasteurized irradiated, and in pasteurized milk throughout the year, G. M. TROUT and E. C. GRESSING. (Mich. Expt. Sta.). (*Jour. Dairy Sci.*, 22 (1939), No. 4, pp. 271–281, figs. 3).—Samples of commercial grade A raw, irradiated pasteurized, and regular pasteurized milks collected at frequent intervals throughout the year were titrated for 4 consecutive days for ascorbic acid content and on the third day of titration were examined for development of oxidized flavor. The average first-day ascorbic acid values in raw milk were 6, 10.5, 8.8, and 7.7 mg. per liter; those for irradiated pasteurized 7.2, 11.1, 14.2, and 10.9; and those for regular pasteurized 9.9, 12.9, 13, and 13 mg. per liter for winter, spring, summer, and fall samples, respectively. The rate of disappearance of ascorbic acid calculated on the third day of titration was greater in winter than in summer and was relatively greater in the raw and irradiated pasteurized than in regular pasteurized samples. Conversely, the stability of ascorbic acid against oxidation was greater in summer than in winter milk. The irradiated milk consistently developed a strong oxidized

flavor from late fall to early spring, raw milk developed a less pronounced though troublesome flavor during the same period, while no oxidized flavor was detected in pasteurized milk throughout the year. None of the above milks were exposed to copper during processing. The direct titration method of determining ascorbic acid was found to be very useful in predicting the presence of catalysts in commercial bottled milk.

Studies in mastitis, I-VI (*Jour. Dairy Res. [London]*, 10 (1939), No. 1, pp. 99-107, figs. 2).—Six phases of this comprehensive study at the National Institute for Research in Dairying are reported.

I. The routine diagnosis of mastitis, J. G. Davis, J. McClemon, and H. J. Rogers (pp. 60-73).—This report describes the cultural characteristics of mastitis and other streptococci found in milk and indicates technics and media for the routine diagnosis of mastitis.

II. A comparison of methods for the detection of subclinical mastitis, J. G. Davis and J. McClemon (pp. 74-80).—Using the results obtained by plating milk twice on Edward's medium as a criterion, 12 methods for the detection of subclinical mastitis have been compared. The correlation between various single tests and also between certain combinations of tests and the standard criterion are indicated. Simple tests such as bromocresol purple paper, the strip cup, and induration are of value in indicating the incidence of mastitis in a herd, but only carefully controlled bacteriological examination in the laboratory can give a true diagnosis.

III. Mastitis in relation to "udder counts," J. McClemon and J. G. Davis (pp. 81-87).—A correlation between udder counts (in milk agar) and true diagnosis for mastitis is indicated. Counts under 100 per cubic centimeter are considered as indicating freedom from infection, while counts of over 500 are considered suggestive and those over 1,000 indicative of mastitis.

IV. Mastitis in relation to the methylene blue reduction test, J. McClemon and J. G. Davis (pp. 88-93).—There was little relationship between the incidence of mastitis and the methylene blue reduction time of milk, indicating that in its present form this test is of no use for the detection of mastitis.

V. Mastitis in relation to cheese-making, J. G. Davis and J. McClemon (pp. 94-103).—The possible causes of the unsuitability of mastitis milk for cheese making are classified and discussed. Abnormal chemical composition of such milk is considered the real factor involved.

VI. General observations, summary, and conclusions, J. G. Davis and J. McClemon (pp. 104-107).—The incidence of mastitis was shown to increase steadily with advancing age of animal. A general summary of the preceding reports is presented.

The value of indirect methods for the detection of mastitis, S. J. Rowland and M. ZEIN-EL-DINE (*Jour. Dairy Res. [London]*, 10 (1939), No. 1, pp. 108-113).—The results of 8 indirect tests for subclinical mastitis were compared with the bacteriological findings in a series of milks. On the basis of agreement with the direct bacteriological method casein number ranked first, followed in order by chloride content, amount and character of centrifuge deposit, solids-not-fat content, bromocresol purple reaction, bromothymol blue reaction, presence of clots, and catalase content.

The physiological types of bacteria in milk in relation to reduction of methylene blue, R. N. DAVIS and K. W. LINES. (Univ. Ariz.). (*Jour. Dairy Sci.*, 22 (1939), No. 4, pp. 209-218, figs. 2).—Approximately 1,000 milk samples studied for physiological types of bacteria present in relation to methylene blue reduction time were found to contain on the average 6.27 percent acid-coagulating bacteria, 55.82 acid-noncoagulating, 11.59 acid-coagulating-gas-proteolytic, 2.28 alkaline, and 2.83 percent inert bacteria. A wide seasonal variation in

physiological types in milk was noted. The acid-noncoagulating types which predominated in most high quality milk were poor reducers of methylene blue, but proteolytic types were good oxygen receivers and played an important role in reduction. Marked variations in physiological types present in individual samples failed to have any material effect on reduction time, suggesting that the associative action between bacteria overshadows any individual variation of reduction power.

The part played by bacteria in the reduction of methylene blue in milk, B. C. HOBBS (*Jour. Dairy Res.* [London], 10 (1939), No. 1, pp. 35-58, figs. 4).—In a study at the London School of Hygiene and Tropical Medicine, pure cultures of the more common forms of organisms present in high-quality raw milk were isolated and subjected to various tests. When grown in raw sterile milk the coliform group of organisms caused most rapid reduction of methylene blue, followed in order by *Streptococcus lactis* and some of the fecal streptococci, *Staphylococcus aureus*, *S. albus*, *S. citreus*, some micrococci, group C hemolytic streptococci, certain strains of *Streptococcus agalactiae*, and aerobic spore bearers. There appeared to be little relationship between rate of oxygen absorption and the rate of methylene blue reduction for the various groups, but a fairly high correlation between the rate of fall in the oxidation-reduction potential and rapidity of reduction. Reduction appeared to be almost entirely a result of the metabolic reactions proceeding on the cell surface of the bacteria, indicating that the methylene blue reduction test affords a good index of the extent of bacterial metabolism in milk.

Methods of measuring gas production, L. A. ALLEN (*Jour. Dairy Res.* [London], 10 (1939), No. 1, pp. 1-6, figs. 4).—This contribution from the University of Reading describes an apparatus and methods for measuring gas production in various dairy products. The apparatus can be readily adapted to either aerobic or anaerobic conditions.

Gas production by *Bacterium coli* and by lactic acid streptococci under different conditions, M. M. HASSOUNA and L. A. ALLEN (*Jour. Dairy Res.* [London], 10 (1939), No. 1, pp. 7-19, figs. 8).—Employing the above-described method, the gas production by *B. coli* and lactic acid streptococci in pure cultures and various combinations was determined. When vigorous strains of *Streptococcus lactis* and *B. coli* were inoculated together in skim milk, a preponderance of the former type inhibited gas production by the latter, but with a larger inoculum of *B. coli* gas production occurred, the amount of gas formed depending on the relative size of inocula of the two organisms. A pure culture of *B. coli* in skim milk yielded only carbon dioxide, while pure cultures in lactose or dextrose broth under similar conditions yielded both hydrogen and carbon dioxide. Thus it appeared that the common gaseous defects in milk and milk products due to coliform organisms are primarily attributable to carbon dioxide and that the effect of hydrogen is negligible. The types of lactic acid streptococci commonly used in starters, whether in pure or mixed cultures in skim milk, skim milk plus yeast extract, or evaporated milk, did not yield measurable quantities of gas.

Protein metabolism and acid production by the lactic acid bacteria in milk: Influence of yeast extract and chalk, M. BRAZ and L. A. ALLEN (*Jour. Dairy Res.* [London], 10 (1939), No. 1, pp. 20-34).—Pure and mixed cultures of various strains of lactic acid bacteria were grown in sterile milk either unsupplemented or with additions of chalk and yeast extract. Growth of these organisms in milk resulted in a concomitant synthesis and degradation of proteins and their split products, with a general tendency to show an increase of protein after several weeks' incubation which was derived primarily from the proteose-peptone fraction. When yeast extract was added to the milk

much more acid was developed and the viability of the culture decreased, presumably due to the lethal effect of the extra acid. Additions of chalk which neutralized the acid markedly increased the rate of proteolysis. There was no evidence that the proteolytic power of the organisms was linked with acid-producing power.

Pasteurizing cream for butter making, C. JENSEN (*North Dakota Sta. Bimo. Bul.*, 1 (1939), No. 5, pp. 25, 26).—A study was made of the effect of temperature and length of the holding period during pasteurization of the cream on the keeping quality of butter. In series 1, comparing temperatures of 145°, 155°, and 160° F. each for 30 min., the average score of fresh butter from the 155° lot was slightly higher than the others. However, the keeping quality of the butter when held at from 40° to 50° increased with increase in pasteurizing temperature. In series 2, comparing 145° for 30 min., 155° for 20 min., and 160° for 15 min., the last lot gave the highest scoring fresh butter while the lot pasteurized at 155° gave butter possessing the best keeping qualities.

A study of the chemistry of incipient oxidation defects in butter, C. R. BAENICOAT and L. S. PALMER (*Minnesota Sta. Tech. Bul.* 134 (1939), pp. 63).—A series of experiments on the oxidation of butter constituents gave evidence that oxidation of the lecithoprotein is responsible for the development of incipient off-flavors such as flat, bitter, stale-storage, and metallic, the latter being most objectionable. The oxidation of the lecithoprotein "membrane" material in cream was evidently transmitted to the triglycerides of the fat globule, since in most instances the oxidation is eventually reflected by an increase in the fat-oxidation value. The membrane oxidized more readily in the presence of catalysts, such as copper or ferrous iron or in the absence of certain natural antioxygenic substances, and may occur long before there is any evidence of oxidation in the butterfat. Other experiments to determine whether nonfat ingredients were oxidizable gave negative results. No evidence of oxidized proteins could be found in commercial butters, and the plasma ingredients proved to be highly antioxygenic. Butters made from washed creams or synthetic creams (butterfat emulsified in egg lecithoprotein) were invariably of rank, metallic, or oxidized flavor. Off-flavors of the metallic type frequently improved during storage, suggesting that oxidation of lecithoprotein may reach a stage where on further oxidation the defective flavor is lost. In such cases a stale-storage flavor finally resulted. Other experiments testing the protective effect of relatively high concentrations of vitamins A, B, C, D, E, and G and nicotinic acid indicated that of these only vitamins C and E possessed any antioxygenic properties. The protective effectiveness of other plasma ingredients, particularly inorganic salts, were much more striking. Theories regarding the oxidation changes occurring in butter are explained at length.

Starter cultures for cheese manufacture: Maintenance of acid-producing activity in cultures of lactic streptococci, H. R. WHITEHEAD and G. J. E. HUNTER (*Jour. Dairy Res. [London]*, 10 (1939), No. 1, pp. 120-132).—The occasional failure of single-strain cultures of streptococci used as starters in Cheddar cheese manufacture is attributed to the apparently spontaneous appearance of bacteriophage. Increasing the amount of inoculum used in the starter and consequently shortening the lag period when starter was added to each new batch of milk proved an effective way of overcoming this difficulty in most instances.

The white particles in mature Cheddar cheese, F. H. McDOWALL and A. K. R. McDOWALL (*Jour. Dairy Res. [London]*, 10 (1939), No. 1, pp. 118, 119).—Analyses of the white specks occurring in mature Cheddar cheese indicated that they were calcium lactate.

Determining the efficiency of ice cream mix pasteurization through the use of the phosphatase test, A. J. HAHN and P. H. TRACY. (Univ. Ill.). (*Jour. Dairy Sci.*, 22 (1939), No. 4, pp. 219-228).—A study of the applicability of the phosphatase test to ice cream mixes indicated that within certain limits this test can be used as a check on the efficiency of pasteurization. Pasteurization temperature of 147° F. or below were not sufficient to result in any appreciable inactivation of the enzyme, indicating that the additional solids in the ice cream mix act as a protective agent for phosphatase. Moreover, pasteurization temperatures of 147° or below sometimes resulted in variable phenol values dependent on the heat treatments previously given dairy products going into the mix, suggesting the necessity of establishing standard phenol values for complete pasteurization at various temperatures. Coloring and flavoring materials also affected the accuracy of the test.

Certain factors affecting the phosphatase test when applied to ice cream, W. J. CAULFIELD and W. H. MARTIN. (Kans. Expt. Sta.). (*Jour. Dairy Sci.*, 22 (1939), No. 4, pp. 261-270).—A study of the influence of various ice cream ingredients on phosphatase behavior during pasteurization indicated that sugar protected this enzyme against inactivation at temperatures of 142°, 143.5°, and 145° F. for 30 min., while portions of the same mix pasteurized without sugar gave negative phosphatase reaction at these temperatures. However, pasteurizing at 150° for 30 min. inactivated the enzyme regardless of the presence or absence of sugar. The use of excessive amounts of certain vanilla flavors significantly influenced the phenol value of the ice cream mix. Additions of small amounts of raw milk or cream to a pasteurized mix could be detected either by the Gilcreas and Davis or the New York field phosphatase test, but at pasteurization temperatures of 150° the holding period had to be materially shortened below 30 min. before it could be detected by either of the above methods. Homogenization, freezing, and holding ice cream at the usual hardening and storage temperatures had no apparent effect on the results of the phosphatase test.

VETERINARY MEDICINE

[Report of work in animal pathology by the Kentucky Station] (*Kentucky Sta. Rpt. 1938, pt. 1, pp. 5-8*).—The work of the year referred to (E. S. R., 79, p. 534) includes transmission experiments with periodic ophthalmia in horses, incoordination in young horses, the finding of equine encephalomyelitis in a brood mare in Fayette County, and a study of paratyphoid bacilli.

[Work in animal pathology by the Massachusetts Station] (*Massachusetts Sta. Bul. 355 (1939), pp. 94-97*).—The work of the year briefly reported upon (E. S. R., 79, p. 534) includes pullorum disease eradication, diagnosis, mortality studies of cottontail and white hare rabbits imported into Massachusetts, infectious bronchitis immunization of poultry, pullorum disease in turkeys, and viability of *Salmonella pullorum*, all by H. Van Roekel, K. L. Bullis, O. S. Flint, and M. K. Clarke; and studies of neoplastic and neoplasticlike diseases, by C. Olson, Jr.

[Work in animal pathology and parasitology by the Wyoming Station] (*Wyoming Sta. Rpt. 1938, pp. 15, 16, 17, 18, 23-25, 27*).—Work with selenium and other mineral elements affecting plant quality, poisonous oat hay and oat straw, poisonous plants, coryza (roup) in chickens, infectious abortion in ewes, calf diphtheria, and equine encephalomyelitis, and transmission experiments with avian coccidiosis are briefly considered in this report (E. S. R., 79, p. 103).

Diseases of animals: Prevention and treatment, F. C. MINETT (*Jour. Roy. Agr. Soc. England*, 99 (1938), pp. 164-194).—A review is given of the progress of work with foot-and-mouth disease, infectious bovine abortion, control of bovine

tuberculosis, and virus diseases of horses, swine, and poultry. A list of 25 references to the literature is included.

[Contributions on animal pathology and parasitology] (*Onderstepoort Jour. Vet. Sci. and Anim. Indus.*, 11 (1938), No. 1, pp. 9-104, 247-255, figs. 54).—Among the contributions presented (E. S. R., 81, p. 274) are: Studies on the Neurotropic Virus of Horsesickness—VI, Propagation in the Developing Chick Embryo, by R. A. Alexander (pp. 9-19) (E. S. R., 78, p. 100); South African Helminths—III, Some Mammalian and Avian Cestodes (pp. 23-50) (E. S. R., 81, p. 274), IV, Cestodes From Columbiformes (pp. 51-61), and V, Some Avian and Mammalian Helminths (pp. 63-104), all by R. J. Ortlepp; and The Toxicity of Some Dipping Fluids Containing Arsenic and Sulphur, by D. B. Steyn and P. M. Bekker (pp. 247-255).

An improved medium for the storage of *Actinomyces necrophorus* cultures, E. A. TUNNICLIFFE. (Mont. Expt. Sta. et al.). (*Jour. Infect. Diseases*, 63 (1938), No. 1, pp. 113-116).—A description is given of a special anaerobic medium especially useful for the storage of *A. necrophorus* cultures. The medium has supported "the uninterrupted viability of nine strains throughout a storage period of 460 days at room temperature. As the medium is regularly employed in this laboratory, routine transfers of the stock cultures of *A. necrophorus* are made every 3 mo. Seven of 10 strains of *A. necrophorus* carried in it from 1.5 to 7 yr., with transfers at intervals of about 3 mo., have retained their pathogenicity."

[Contributions on helminth parasites] (*Helminthol. Soc. Wash. Proc.*, 6 (1939), No. 1, pp. 1-8, 10, 11, 21-23, 29, 30, figs. 2).—Contributions presented are: Two New Nematodes (Trichostrongyloidea) From Rodents, by G. Dikmans (pp. 1-4) (U. S. D. A.); Notes on Parasites of Horses in Hawaii, by A. O. Foster and J. E. Alicata (pp. 4-8) (Univ. Hawaii et al.); and On the Life History of *Moniczia expansa* and *Cittotaenia* sp. (Cestoda: Anoplocephalidae), by W. H. Krull (pp. 10, 11), Effectiveness of the Swine Sanitation System in Controlling Swine Stomach Worms in the South, by D. A. Porter (pp. 21-23), and A Note on the Parasite Fauna of the Hawaiian Islands, by L. E. Swanson (pp. 29, 30) (all U. S. D. A.).

Life history of the nematode *Cooperia curticei*, and development of resistance in sheep, J. S. ANDREWS. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 58 (1939), No. 10, pp. 771-785, figs. 3).—The results of an investigation, conducted through 1934, 1936, and 1937, of the life history of *C. curticei*, a nematode parasitic in the small intestine of sheep and goats, with a more or less cosmopolitan distribution, are reported. The findings reveal the life history to be very similar to that of other trichostrongyles. Infective larvae developed from the eggs in about 5 days at room temperature. They lost their sheaths soon after entering the host and migrated into the crypts of the intestinal mucosa about 3 days after infection. They underwent the third ecdysis in the crypts on about the fourth day, and returned to the lumen of the intestine on about the fifth day after infection, where they remained for the balance of their life. The fourth ecdysis occurred on the ninth day, the worms matured on about the fourteenth day, and eggs were found in the feces as early as the fifteenth day after infection. Sex differentiation of the larvae was possible at the beginning of the fourth stage. Lambs receiving daily doses of larvae over a relatively long period of time developed a resistance against superinfection. The resistance was evidenced by the production of nodules about the larvae in the crypts of the intestinal mucosa. The nodules were found to be similar in structure to those reported by other workers. A list is given of 44 references to the literature cited.

The coyote as a host to *Physaloptera felidis* Ackert 1936, O. W. OLSEN, R. FENSTERMACHER, and B. S. POMEROY. (Minn. Expt. Sta.). (*Cornell Vet.*, 27 (1937), No. 3, p. 327).—Nematodes to the number of 20 that were collected from a coyote trapped in Minnesota were identified as *P. felidis*. The species was described by Ackert in 1936 from cats in Kansas (E. S. R., 76, p. 64).

Some notes on the chemical control of the free-living stages of bursate nematodes, I. W. PARNELL (*Canad. Jour. Compar. Med.*, 3 (1939), No. 3, pp. 84-87).

Susceptibility of the "gopher" (*Citellus richardsonii* (Sabine)) to *Leptospira icterohaemorrhagiae*, J. T. SYLVESTER, W. W. STILES, and G. P. BERRY (*Soc. Expt. Biol. and Med. Proc.*, 39 (1938), No. 1, pp. 113-115).—Evidence is presented of the susceptibility of the Richardson ground squirrel (*C. richardsonii*) to the etiological agent of Weil's disease *L. icterohaemorrhagiae*.

Flagellar antigens of organisms of the genus *Listerella*, J. S. PATERSON (*Jour. Pathol. and Bact.*, 48 (1939), No. 1, pp. 25-32, pl. 1).—A description is given of the flagellar antigenic structure of 27 strains of *Listerella* from a variety of animals.

A comparative study of *Listerella* and *Erysipelothrix*, M. BARBER (*Jour. Pathol. and Bact.*, 48 (1939), No. 1, pp. 11-23, pls. 4).—A comparison of five strains of *Listerella* and six of *Erysipelothrix* is reported. Since it has been impossible to decide finally upon their classification, the two generic names are retained.

Survival of worm parasite infection on New York State pastures, D. W. BAKER. (Cornell Univ.). (*Cornell Vet.*, 29 (1939), No. 1, pp. 45-48).—Evidence presented in this progress report indicates that in the vicinity of Ithaca, N. Y., the infective stages of the various species of small gastrointestinal worms found in native sheep and calves will remain viable for periods of at least 21 mo. in the case of sheep parasites and at least 9 mo. in the case of bovine parasites.

Allergy in *Brucella* infections, P. MORALES-OTERO and L. M. GONZALEZ. (Univ. P. R.). (*Soc. Expt. Biol. and Med. Prod.*, 40 (1939), No. 1, pp. 100-102).—Studies under way have shown that there is no correlation between cutaneous allergy to *Brucella* and other "immunological reactions, such as agglutination, complement-fixation, and opsono-cytophagic index." It is concluded that the "cutaneous test should be of value in epidemiological investigations, but until further work is done the cutaneous reaction should not be considered as proof of present or past infection, since it only shows the development of a state of hypersensitiveness in persons that have been in close contact with infected material."

Serological studies on mastitis, F. R. SMITH and C. S. MUDGE (*Soc. Expt. Biol. and Med. Proc.*, 40 (1939), No. 1, pp. 45-48).—The studies reported have shown that cow sera may contain "streptococcal antibodies which appear to be type-specific. There is evidence of a correlation between the presence of *Streptococcus mastitidis* in the herd and the occurrence of agglutinating antibodies in the serum of the individual cows. It appears probable that infection in an individual herd may be due to a specific type under group B."

The transmission of lymphocytic choriomeningitis by mosquitoes, L. T. COGGESHALL (*Science*, 89 (1939), No. 2318, pp. 515, 516).—Transmission experiments with lymphocytic choriomeningitis occurring among rhesus monkeys have demonstrated the ability of the yellow-fever mosquito to transmit the disease to guinea pigs through its bite. The mosquitoes are capable of transmitting the virus as early as the fourth day and at least as late as the fifteenth day after feeding on an infected animal.

Serologic and immunologic studies relative to the viruses of human and swine influenza, D. R. SEAW, A. S. KENNEY, and J. Stokes, JR. (La. State Univ. et al.). (*Amer. Jour. Med. Sci.*, 197 (1939), No. 2, pp. 247-253).—A description is given of the development of neutralizing antibodies against the human virus in the sera of swine exposed to human epidemic influenza and the absence in the same sera of corresponding antibodies for swine virus. The appearance in the cross-neutralization tests of antigenic differences in the human influenza viruses is also described and discussed.

Johne's disease infection of laboratory animals with aid of paraffin oil, W. M. MOHLER (U. S. D. A.). (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 6, pp. 590-594, figs. 2).—Experiments have shown that when cultures or tissues containing *Mycobacterium paratuberculosis* are emulsified with paraffin oil and then inoculated into guinea pigs, the animals usually develop symptoms of the disease within 2 or 3 weeks and succumb in from 30 to 90 days, although some may linger as long as 5 mo. "In previous experiments these laboratory animals had always proved refractory to inoculations with either saline or distilled water suspensions of material containing *M. paratuberculosis*. Therefore, in paraffin oil we have a new tool or vehicle which, when mixed with *M. paratuberculosis*, is highly capable of infecting laboratory animals, either by reducing their resistance or by increasing the antigenic property or the virulence of the causal organism."

The susceptibility of voles to human and bovine strains of tubercle bacilli, A. Q. WILLS (*Brit. Jour. Expt. Path.*, 19 (1938), No. 5, pp. 324-328).—It has been found that the amount of human tubercle bacilli which will produce demonstrable disease after intraperitoneal injection in the vole (*Microtus agrestis*) after 1 mo. is at least 1 mg. "Extensive and progressive disease has resulted in 1 mo. after injection in all the voles which were injected with bovine tubercle bacilli in amounts varying from 1 mg. to 0.00001 mg. It is suggested that a dose of 0.001 mg. moist weight of culture of tubercle bacilli injected intraperitoneally into voles should distinguish unfailingly between human and bovine tubercle bacilli in 1 mo."

Further observations on acquired immunity to the tick *Dermacentor variabilis* Say, W. TRAGER (*Jour. Parasitol.*, 25 (1939), No. 2, pp. 137-139).—The author found that guinea pigs can be partially immunized "to larvae of *D. variabilis* by injecting them with extracts of the cephalic glands, salivary glands, or digestive tract of partially engorged adult female ticks, or of the salivary glands of unfed adult females. The serum of rabbits previously infested with *D. variabilis* shows specific complement fixation with a larval tick extract antigen."

The mode of action of sulfanilamide on streptococcus, II, F. P. GAY, A. R. CLARK, J. A. STREET, and D. W. MILES (*Jour. Expt. Med.*, 69 (1939), No. 5, pp. 607-624).—It is concluded that sulfanilamide not only does not completely destroy the *Streptococcus hemolyticus* but does not even impair its innate virulence. "It acts upon the streptococcus not only by inhibiting growth but by a temporary inhibition of hemotoxin formation, but only under certain conditions. The drug does not neutralize hemotoxin already formed. No significant effect of sulfanilamide on the formation of leucocidin or fibrinolysin by streptococcus has been evident in our experiments."

The mode of action of sulphanilamid, P. A. SHAFFER (*Science*, 89 (1939), No. 2320, pp. 547-550).

Comparative therapeutic effects of sulfapyridine in experimental *Staphylococcus aureus* infections in mice, E. A. BLISS and P. H. LONG (*Soc. Expt. Biol. and Med. Proc.*, 40 (1939), No. 1, pp. 32-34).—The authors find it quite apparent that the slight therapeutic effect of sulfapyridine is definite

enough to warrant careful clinical trials of the drug in severe staphylococcal infections.

The enzyme urease and the occurrence of ammonia in maggot-infected wounds, W. ROBINSON and F. C. BAKER. (U. S. D. A.). (*Jour. Parasitol.*, 25 (1939), No. 2, pp. 140-155).—The larvae of *Lucilia sericata*, recently used as surgical maggots, have been found to contain "the enzyme urease in their tissues and excretions. Urease is present both in nonsterile maggots and in those reared under aseptic conditions. This enzyme, in breaking down urea, produces ammonia abundantly in maggot-infected wounds."

A list is given of 22 references to the literature.

Horses as possible means of spread of Bang's disease among cattle, C. P. FITCH and R. E. DODGE. (Minn. Expt. Sta.). (*Cornell Vet.*, 29 (1939), No. 1, pp. 29-31).—The results of testing and retesting two groups of cattle, with the details given in table form, are presented to show a possible transmission from horses and that this phase of Bang's disease control merits careful attention. It is pointed out that under field conditions, and especially in area work, infected horses which are allowed to remain on the farm present a potential hazard.

Results of vaccination with *Brucella abortus* strain 19 in an infected herd, C. M. HARING. (Univ. Calif. and U. S. D. A.). (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 6, pp. 587-589).—A report is made on the use since 1933 of U. S. D. A. Bureau of Animal Industry *B. abortus* strain 19 in vaccinating all heifers born to an infected State dairy herd in California. A preliminary report of the herd was published in 1938 (*E. S. R.*, 78, p. 699).

"As these heifers came into production, they were placed with the old, nonvaccinated cows, many of which were proved to be shedders of *B. abortus*. As the utility of the old cows has decreased, they have been gradually eliminated until now only 10 are left, 1 of which was still shedding *B. abortus* in 1938. No cows or heifers have been brought into the herd from the outside. The vaccinated animals now in milk production total 51, or 19 percent more than the total number in the old, infected herd in 1933. The vaccinated cows have produced 146 normal calves. There have been five abortions and five stillbirths among vaccinated cows, but inoculations and blood tests indicate that these were not caused by *B. abortus*. *B. abortus* of virulent type (not strain 19) was isolated from 2 of the vaccinated cows, neither of which aborted and 1 of which had a titer of over 1:50 when vaccinated at the age of 24 mo. Continued recent tests have failed to demonstrate the organism in the milk or vagina of these 2 cows. There is no evidence that the vaccine organism was transmitted to any of the old, nonvaccinated cows in the herd by association with the vaccinated heifers. When vaccinations were begun, 17 unbred heifers between 12 and 32 mo. of age were given full vaccine doses, and the vaccination titers of some of these animals did not recede to below 1:25 for about 4 yr. No significant persistence of titers has occurred in the balance of the heifers vaccinated between 4 and 12 mo. of age."

A study of the possible relationship between nonspecific mastitis and streptococcal infection of the bovine udder, E. H. PETERSON and E. G. HASTINGS. (Wis. Expt. Sta.). (*Cornell Vet.*, 29 (1939), No. 1, pp. 11-24, figs. 3).—Experiments conducted with 10 cows are reported, followed by an account of pathological findings, which have shown that nonspecific mastitis "apparently lowers the resistance of the mammary gland to infection with *Streptococcus agalactiae*. *S. agalactiae* can be quite easily transmitted to quarters affected with nonspecific mastitis by external infection of the teat. Quarters affected with nonspecific mastitis are readily susceptible to internal infection with small numbers of *S. agalactiae*. The physical changes produced in the milk as a result of the super-

imposed bacterial infections are quite proportional to the degree of involvement of the quarters with nonspecific mastitis. The pathological changes produced in mammary tissue by nonspecific inflammation are identical to the changes observed to be associated with chronic streptococcal mammary infections with the exception that a discontinuous infiltration of polymorphonuclear leucocytes, not observed in the former case, is a characteristic of chronic streptococcal infections of the mammary gland. The suggestion is made that nonspecific mastitis is the primary or predisposing condition and *S. agalactiae* a secondary invader in chronic bovine mastitis."

Parturient hemoglobinemia of dairy cows, D. E. MADSEN and H. M. NIELSEN. (Utah Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 6, pp. 577-586, figs. 2).—The authors have found parturient hemoglobinemia to be a disease of high-producing dairy cows, occurring from 2 to 3 weeks following calving and characterized by hydremia, oligocythemia, icterus, and usually hemoglobinuria. The disease usually occurs in the stable season only and attacks cows giving birth to the third to sixth calf. The disease is more prevalent on certain farms than others, and there is some tendency toward recurrence in the same animal. The incidence of the disease appears to be increasing. "Bacteriological and protozoological examinations were negative, and the disease could not be transmitted by inoculations. No enterotoxins could be demonstrated. In Europe the disease is restricted to infertile farms and is more prevalent following a drought. In Utah and Idaho it occurs most commonly when cows are fed rations including sugar beet byproducts. The blood plasma of affected cows was found to be extremely low in inorganic phosphorus."

A study of *Spirillum ovis* infection in a group of ewes maintained under observation for two successive lambing seasons, D. W. BAKER and W. S. STONE. (Cornell Univ.). (*Cornell Vet.*, 29 (1939), No. 1, pp. 32-34).—The authors' experiments during an outbreak of abortion in a flock of about 80 ewes indicate that *S. ovis* infection was not maintained in a flock which received good care during the subsequent period of pregnancy when a young noninfected ram was used as the sire. "The etiology of this outbreak of abortion in ewes seems to have been well established, but the epidemiology was not determined and there is no obvious explanation for its sudden appearance. Cultures of a spirillum were recovered from the aborted fetuses, and microscopic examination of sections from the liver lesions showed narrow areas of necrosis with infiltration of neutrophils and eosinophils around the blood vessels and portal triad. Eight ewes which had aborted fetuses that were known to be infected with *S. ovis* in 1937 were kept under observation for 1 yr. All of them lambed normally in the spring of 1938, indicating either a loss of infection or a loss of virulence of the organism during the period. No abortion-producing agent could be demonstrated by feeding moldy bean pods to pregnant ewes."

Effect of ferric sulphate and copper sulphate on coccidiosis in lambs, L. A. SPINDLER. (U. S. D. A.). (*North Amer. Vet.*, 20 (1939), No. 5, pp. 33-38, fig. 1).—An experiment conducted with a view to determining whether the daily administration of a dilute aqueous solution of ferric sulfate and copper sulfate to lambs might alter their resistance to coccidia and other gastrointestinal parasites is reported. Lambs naturally infected with coccidia (*Eimeria* spp.) were experimentally infected at intervals with larvae of *Haemonchus contortus*, *Cooperia curticei*, *Oesophagostomum columbianum*, and *Chabertia ovina* to lower or break down their resistance to coccidia. The administration of the iron-copper solution apparently resulted in the production of a resistance that inhibited to some extent the numerical increase of the parasites in the treated animals. "No significant difference was noted either in the number of helminth

eggs in the feces or in number of worms found at necropsy in the test and control animals."

Experimental trichostrongylosis in sheep and goats, J. S. ANDREWS. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 58 (1939), No. 10, pp. 761-770, fig. 1).—Observations of cases of trichostrongylosis produced in host animals raised in cages relatively free from parasites and experimentally infected with known numbers of infective larvae of *Trichostrongylus* spp. are reported, the details being given in tables. In the course of the work infestations of from 10,889 to 177,756 worms of *Trichostrongylus* spp. were established in sheep and goats by feeding from 78,000 to 440,000 infective trichostrongyle larvae. These infestations produced a profuse diarrhea 13 to 59 days after the first dose of larvae and caused the death of the host 3 to 53 days later. In three instances death occurred before the worm eggs appeared in the feces, thus making impossible a positive diagnosis of these cases prior to necropsy.

In those animals dying of trichostrongylosis no anemia was observed. There was, however, an accumulation of serous fluid in the abdomen, diffuse inflammation of the small intestine, and a friable condition of the liver. Histological examination of the tissues indicated that death was caused by a generalized circulatory disturbance which had given rise to chronic passive congestion accompanied by degenerative changes in the liver and kidneys. The extreme emaciation observed in some of the animals that survived the infestation for some time was apparently due to partial starvation and to dehydration of the tissues caused by the diarrhea. Animals subjected to daily doses of 3,000 or more larvae succumbed to the infestation, whereas those subjected to smaller daily doses were able to build up sufficient resistance to survive. The evidence obtained indicated that goats were slightly more susceptible to the infestation than sheep.

A list of 14 references to the literature cited is included.

Caseous lymphadenitis in milk goats, J. N. SHAW and L. SEGNETTI. (Oreg. Expt. Sta.). (*North Amer. Vet.*, 20 (1939), No. 5, pp. 39, 40).—A report is made of the isolation of an organism similar to, if not identical with, *Corynebacterium ovis* from a parotic abscess in a milk goat. "Cultural and morphological characteristics of this organism are identical with those of *C. ovis* recovered from caseous lymphadenitis in sheep. Guinea pigs inoculated with this organism developed a marked orchitis and abscesses characteristic of *C. ovis* infection."

Chronic myeloid leukemia of a hog? R. F. LANGHAM and E. T. HALLMAN. (Mich. State Col.). (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 6, pp. 653, 654, figs. 3).

Studies on eastern equine encephalomyelitis, II, III, L. S. KING (*Jour. Expt. Med.*, 69 (1939), No. 5, pp. 675-704, pls. 2, figs. 9).—This contribution is continued (E. S. R., 80, p. 398).

II. Pathogenesis of the disease in the guinea pig (pp. 675-690).—It was found that in the guinea pig the virus of eastern equine encephalomyelitis injected peripherally invades the blood stream and passes directly from the blood stream into the brain. This seems to be the principal, though not necessarily the exclusive, mode of pathogenesis. Once in the nervous system the further spread of the virus may occasionally be determined by anatomical connections.

III. Intraocular infection with fixed virus in the guinea pig (pp. 691-704).—A report is made of the behavior of a fixed strain of eastern equine encephalomyelitis virus studied in guinea pigs after intraocular inoculation. The susceptibility when thus injected lies midway between the highly virulent intracerebral and the quite avirulent peripheral routes. The virus must act for 10 to 13 hr. in order to induce a fatal infection. Removal of the inoculated eyeball before this interval almost always prevents fatality, although it may allow immunity to develop.

Recovery of the virus of equine encephalomyelitis (western type) from human blood serum. B. HOWITT (*Science*, 89 (1939), No. 2319, pp. 541, 542).—Recovery from adult human blood serum even after prolonged storage in the refrigerator is reported.

Encephalomyelitis in monkeys. R. W. G. WYCKOFF (*Science*, 89 (1939), No. 2319, pp. 542, 543).—When a massive dose of either eastern or western virus of equine encephalomyelitis is instilled intranasally into a young rhesus monkey, it will in most instances succumb to a fatal infection. Symptoms of the two forms of virus have been similar except that as in other animals the eastern has run a shorter course. "Dropping virus into the eye has not resulted in either disease or measurable antibodies. Eastern virus injected intralingually and western virus introduced by stomach tube have proved fatal, but we have not diseased healthy animals by keeping them caged with sick ones." Hyperimmune horse serum has provided passive protection against nasally instilled virus. Incomplete protection has been furnished by serum administered within 3 hr. of infection. In numerous trials no beneficial effect has resulted from such a serum given at and after the time of first temperature rise, even when this serum was equivalent in amount to the injection of 500 cc. into a 150-lb. man. "Animals twice vaccinated with crude chick embryo vaccine have in all but one instance been completely protected against massive doses of intranasal virus. This vaccination has produced antibodies which were present in high titer after eastern, in lower titer after western vaccine injection."

Equine encephalomyelitis and its control. B. M. LYON (*North Amer. Vet.*, 19 (1938), No. 12, pp. 22-30).—This contribution relates particularly to immunity, it having been shown that from the diseased chick embryo equine encephalomyelitis virus may be obtained in a concentration approximately 100,000 times greater than that found in diseased horse brain. Formolized chick embryo vaccine is more antigenic and therefore more effective for immunization than horse brain vaccine. "Horses, as well as guinea pigs, given two doses of chick vaccine may be solidly protected against massive intracerebral injections of virus which proved fatal not only to all unvaccinated animals but to all those animals receiving the horse brain vaccine. Seven days following a single dose of 10 cc. chick vaccine two out of three horses were completely and one partially protected against intracerebral virus exposure fatal to a corresponding number of unvaccinated horses. Tests to show the full duration of protection are incomplete, since sufficient time has not elapsed to show any appreciable lessening of the immunity. To date, however, horses vaccinated with 2 doses of the chick vaccine 4 mo. previous to intracerebral virus exposure were solidly protected against a virus injection fatal to an equal number of unvaccinated horses. Protection has been shown in guinea pigs over a period of 6 mo. Complete protection may be induced with a bivalent vaccine containing eastern and western formolized virus equivalent in amount to the respective monovalent vaccines against both eastern and western virus exposure.

"Following the distribution of approximately 1,500,000 doses during the 1938 season of the chick vaccine, no protection failures have been recorded after completion of the treatment. The disease was recorded up to 5 days following the initial dose, indicating preinfections. Our studies to date indicate a marked increased degree of protection from a 2-dose treatment over that obtained from a single dose, and from our present knowledge we must not rely upon a false sense of security obtained from a single-dose treatment."

The successful treatment of meningo-encephalitis, associated with canine distemper, with sulfanilamide. M. L. MORRIS and T. J. MURRAY. (Rutgers Univ. et al.). (*Science*, 89 (1939), No. 2308, p. 274).—The administration of

sulfanilamide in the treatment of dogs suffering from meningoencephalitis associated with canine distemper resulted in the cure of 13 of 14 dogs when sufficient dosage was given by mouth or subcutaneously to maintain the sulfanilamide blood level at not less than 15 mg. percent. It is desirable to maintain this blood sulfanilamide level and that the administration of the drug be started in the initial stage before extensive pathological changes are manifest.

Immunity to salmon poisoning follows treatment of affected dogs with sulfanilamide, J. N. SHAW and C. R. HOWARTH. (Oreg. Expt. Sta.). (*North Amer. Vet.*, 20 (1939), No. 5, pp. 67, 68).—Report is made of an experiment which has shown that immunity to salmon poisoning in dogs is produced by feeding parasitized salmon and treating with sulfanilamide when symptoms appear.

Ineffectiveness of sulfanilamide in the treatment of canine filariasis, H. W. BROWN. (Univ. N. C.). (*Soc. Expt. Biol. and Med. Proc.*, 39 (1938), No. 1, pp. 98-100).—The oral administration of from 0.057 to 0.187 gm. of sulfanilamide per kilo weight to dogs as a single daily dose for a period ranging from 15 to 36 days was ineffective in the treatment of *Dirofilaria immitis*, as judged by microfilaria counts. A week after the conclusion of the sulfanilamide therapy by mouth one dog was given a series of intramuscular injections of a soluble sulfonamide without effect on *D. immitis*. "This treatment consisted of two daily intramuscular injections of 10 cc. of 2.5 percent solution of disodium 4-sulfamidophenyl-2-azo-7-acetylamino-1-hydroxynaphthalene, 3,6-disulfonate (Prontosil, Winthrop). The drug was administered over a period of 9 days. The microfilaria count, which was 250 per cubic centimeter before treatment, rose to 420 on its completion."

Observations on a natural infection with Strongyloides in the dog, D. L. AUGUSTINE and D. G. DAVEY (*Jour. Parasitol.*, 25 (1939), No. 2, pp. 117-119).—The authors conclude from limited observations that while *Strongyloides* of human origin can be readily transmitted to dogs and cats under laboratory conditions, "the species occurring naturally in dogs probably is distinct and should be identified as *Strongyloides canis* Brumpt, 1922."

Some pathological conditions of the anterior portions of the digestive tract of poultry, H. E. BIESTER and L. H. SCHWARTZ. (Iowa State Col.). (*North Amer. Vet.*, 20 (1939), No. 5, pp. 41-44, figs. 3).

A study of fowl paralysis, C. W. BARBER (*Cornell Vet.*, 29 (1939), No. 1, pp. 41-44).—Report is made on the antemortem diagnosis and therapeutic value of wheat germ oil for fowl paralysis. The duration of the disease was not appreciably affected by the oil.

Propagation of the virus of vesicular stomatitis in the chick embryo, E. A. EICHORN and C. A. MANTHEL. (U. S. D. A.). (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 6, pp. 608-611).—Vesicular stomatitis virus dried in vacuo and held in a refrigerator remained viable for at least 5 mo. "Vesicular stomatitis virus (New Jersey strain) can be propagated in both the developing chick embryo and chorioallantoic membrane. Eleven-day-old embryos are the most suitable, with 40 to 48 hr. of incubation for maximum virus production in the egg. The virulence is increased after successive passages in the chick embryo. Egg-propagated virus is immunologically identical with animal-propagated virus."

The life history of Hymenolepis exigua, a cestode of poultry in Hawaii, J. E. ALICATA and E. CHANG. (Hawaii Expt. Sta.). (*Jour. Parasitol.*, 25 (1939), No. 2, pp. 121-127, figs. 19).—A report is made of an experimental study of the development of the tapeworm *H. exigua* in the intermediate host (amphipod, *Orchestia platensis*) and in the final host, which is the chicken. "Eggs of this parasite, when ingested by amphipods, were found to develop

during a period of about 12 days to the cysticeroid stage capable of infecting chicks. (Cysticeroids fed to week-old chicks developed to maturity in the duodenum and eggs passed in the droppings of the birds 9 to 10 days after experimental infection. Sowbugs (*Porcellio lacris*), beetles (*Tenebroides nana*), houseflies (*Musca* sp.), and undetermined species of earthworms which were exposed to infection with eggs of *H. exigua* failed to become infected."

Preliminary note on the life history of *Subulura brumpti*, a common cecal nematode of poultry in Hawaii, J. E. ALICATA. (Univ. Hawaii). (*Jour. Parasitol.*, 25 (1939), No. 2, pp. 179, 180, fig. 1).—In studies on cecal worms parasitizing chickens in Hawaii, *S. brumpti* was found in 42 out of 50 sets of ceca examined from birds obtained in Honolulu markets. The following five species of insects collected in poultry farms were found naturally infected with encysted larvae of *S. brumpti*, namely, "(Coleoptera) *Dermestes vulpinus*, *Gonocephalum seriatum*, *Ammophorus insularis*, *Alphitobius diaperinus*, and (Dermaptera) *Euborellia annulipes*. An examination of 20 specimens of insects collected in 1 poultry farm near Honolulu revealed the following incidence of infection: *A. diaperinus* 75 percent, *A. insularis* 90 percent, *E. annulipes* 70 percent. Encysted larvae of *S. brumpti* were also found in grasshoppers, *Conocephalus saltator*, 15 days after they were experimentally fed embryonated eggs of this parasite."

A report of swine erysipelas in turkeys, A. S. ROSENWALD and E. M. DICKINSON. (Oreg. Expt. Sta.). (*Cornell Vet.*, 29 (1939), No. 1, pp. 61-67).—A report is made of three outbreaks of swine erysipelas septicemia, thought to be the first in Oregon turkeys, together with a preliminary report of the studies conducted. The possible connection with ovine polyarthritis, the seasonal occurrence, and the preponderance of males affected were noted. This affection of sheep is not known to exist in the section of Oregon where the turkey outbreaks occurred.

Blood alterations in typhlohepatitis of turkeys, with notes on the disease, E. P. JOHNSON and C. J. LANGE. (Va. Expt. Sta.). (*Jour. Parasitol.*, 25 (1939), No. 2, pp. 157-167, figs. 6).—The authors have found *Histomonas meleagridis* in cecal discharges of carrier chicks to be extremely pathogenic, as compared to this protozoan in other material and to other channels of administration when introduced into the rectum of turkeys held in a suspended position. "The average differential leucocyte count of normal turkeys maintained under the conditions of this experiment is as follows: Heterophiles 43.4, eosinophiles 0.9, basophiles 3.2, lymphocytes 50.6, and monocytes 1.9 percent. Experimental blackhead disease of turkeys results in a marked disturbance in the blood picture which is characterized by (1) a marked heterophilia of from 8 to 21 percent within 24 hr. of receiving the infective material, (2) a persistence of the heterophilia until death, (3) an irregular monocytosis in some cases, especially in those receiving subcutaneous implantations of infective material, [and] (4) myelocytosis and anemia usually preceding the fatal termination. The sudden marked heterophilia following introduction of infective material indicates that the histomonads penetrate the cecal epithelium and establish themselves in some parenteral position where toxic material results within 24 hr. Natural cases of typhlohepatitis were found to have very similar leucocyte disturbances to those found in the experimentally infected birds. An extensive lesion in the proventriculus due to the administration of *H. meleagridis* by way of the mouth is described and illustrated. In no case could intravascular protozoan forms be demonstrated in the experimentally infected birds. The rounded forms . . . are interpreted as macrogamete stages of a blood protozoan resembling *L[eucocytozoon] smithi* and are not related to *H. meleagridis*."

Observations on *Capillaria contorta* in turkeys, M. W. EMMEL. (Fla. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 6, pp. 612-615, figs. 4).—A report is made of observations on 3 flocks of turkeys infested with *C. contorta*, consisting of 800, 1,200, and 500 birds, respectively, which showed that the characteristic symptoms were indigestion, weakness, droopiness, emaciation, frequent swallowing, and a penguinlike position of the body. "Macroscopic lesions consisted of catarrhal and hemorrhagic inflammation, thickening, necrosis, and sloughing of the mucosa of the esophagus and crop. Microscopic lesions consisted of areas of hyperplasia, hypertrophy, necrosis, and hemorrhage in the layers of epithelium. *C. contorta* did not penetrate deeper than the basement membrane. A satisfactory treatment consisted of feeding the flocks 5 percent of sulfur in the regular mash for a period of 3 weeks."

Clostridium infection in turkeys, R. FENSTERMACHER and B. S. POMEROY. (Minn. Expt. Sta.). (*Cornell Vet.*, 29 (1939), No. 1, pp. 25-28).—Report is made of an outbreak of disease in a flock of approximately 1,000 turkey hens in which there was a mortality of 2 percent. Losses occurred at the beginning of the breeding season. The atrium of infection was probably wounds that occurred at the time of breeding. The anaerobic infection produced subcutaneous emphysema and edema around the head and thigh. *C. septicum*, *C. welchii*, and *C. sordellii*, and a Gram-positive coccus were isolated from the internal organs and subcutaneous tissue of 2 turkey hens.

A survey of the blood parasites of birds caught for banding purposes, C. G. HUFF (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 6, pp. 615-620, fig. 1).—A report is made of the parasites of the blood of wild birds based upon smears taken over a period of 10 yr., the details of which are given in three tables.

AGRICULTURAL ENGINEERING

[Agricultural engineering investigations of the Massachusetts Station] (*Massachusetts Sta. Bul.* 355 (1939), pp. 52, 53).—This work included a cranberry storage investigation, by C. I. Gunness, H. J. Franklin, and C. R. Fellers; and a study of frost protection on cranberry bogs and construction of a tobacco seed cleaner, both by Gunness.

[Agricultural engineering investigations by the Wyoming Station] (*Wyoming Sta. Rpt.* 1938, p. 30).—It is noted that four fields have been fallowed with the Peacock damming lister, the eccentric one-way plow, the common stubble plow with the moldboard removed, and the duckfoot cultivator, respectively, with no resulting run-off or soil blowing on any of these fields.

Surface water supply of the United States, 1937.—Part 2, South Atlantic slope and eastern Gulf of Mexico basins (*U. S. Geol. Survey, Water-Supply Paper* 822 (1938), pp. VI+266, pl. 1).—This report presents measurements of flow made on streams in these basins during the year ended September 30, 1937.

Ground-water resources of the Holbrook region, Arizona, M. A. HARBELL and E. B. ECKEL (*U. S. Geol. Survey, Water-Supply Paper* 836-B (1939), pp. IV+19-105, pls. 10, fig. 1).—The Holbrook region includes most of the drainage area of the Little Colorado River in Arizona, exclusive of the Navajo country.

Semiarid conditions prevail except in the mountainous areas to the south. Dry farming has been unsuccessful. Irrigation is practiced to a very slight extent, its chief restrictions being the lack of water of proper quality and quantity. Cattle and sheep grazing have been conducted successfully and are the chief industries. Sufficient well-water supplies may be developed for present herds, but the region as a whole seems not adapted to further expansion of the grazing industry under present conditions of vegetative cover and its use.

The total dissolved solids in the waters range from 80 to 6,197 p. p. m. Waters from Recent alluvial materials, the Moenkopi formation, and the Chinle formation are commonly high in dissolved mineral matter. The best waters come in large part from the base of the lava flows or of the Tertiary sands and from the Coconino sandstone.

The relationship of stream flow to precipitation on the Salt River watershed above Roosevelt Dam, C. K. COOPERIDER and G. G. SYKES (*Arizona Sta. Tech. Bul. 76 (1938). pp. [3]+69, figs. 10*).—A foreword by the director of the station notes that "this bulletin is published by the agricultural experiment station of the University of Arizona in cooperation with the Southwestern Forest and Range Experiment Station in order that the important information it contains may be made available at once to the people of Arizona, to whom such facts are vital in their management of land resources." Its contents deal with the importance of watered areas, need for knowledge about factors that affect water yield, watershed and precipitation characteristics affect water yield, records and analyses, close relationship between precipitation and stream flow on the upper part of the watershed, further tests of relationships of fall and flow, long-time trends, why summer precipitation contributes so little to stream flow, precipitation-stream flow relationships in the lower part of the southwestern watersheds, and application of findings in watershed management.

Flow of water in irrigation and similar canals, F. C. SCOBEE (*U. S. Dept. Agr., Tech. Bul. 652 (1939), pp. 79, pls. 24, figs. 5*).—On the basis of tests carried on since 1913 (*El. S. R., 33, p. 183; 70, p. 838*), this bulletin presents a detailed analysis of the factors involved in the design and performance of canals supplying water for irrigation or other uses. Particular attention is given to the choice to be made among various empirical formulas for determining the value of n , the coefficient of hydraulic roughness. In addition to evaluating n under conditions such that the design will be satisfactory at the critical part of the season, the author finds it necessary to consider prevailing wind direction and notes other important design factors as follows:

"In the design of earth channels having a trapezoidal form when constructed, the computations should be based on the expectation that the canal will take an elliptical form within a short time and thereafter maintain this shape unless altered artificially. Capacity of old rough concrete canals can be materially increased at a fraction of the capital charge for the original construction. Shot concrete should be surface-treated [by striking with a rectangular blade] to secure high capacity. If capacity is sufficient . . . water tightness is better assured without surface treatment, as this includes a tendency toward more porous concrete. Initial high capacity due to smooth surfaces is not a permanent feature where muddy waters predominate. Such water increases the capacity of a very rough channel and decreases the capacity of a very smooth one. Determinations of the values of n in experimental research work should not be conducted on the basis of the surface slope. The energy slope is the effective quantity and agrees with the surface slope only for uniform flow, and uniform flow cannot be assumed to be present. Generally it is not. If cross-sectional areas are developed at the ends of a test reach, no matter how uniform the flow looks or should be, it is generally found that these areas are unlike. Hence the velocities are unlike and have different investments of velocity head in their total energy contents."

An outline of the water facilities program (*U. S. Dept. Agr., Soil Conserv. Serr., [pp. 23], figs. 11*).—A popular, profusely illustrated outline is given, indicating what the Federal water facilities program provides, where it applies, who may benefit, manner of handling construction and installation, limitation of size of single projects, repayment of loans, plans for tenants, etc.

Studies on Raritan River pollution, II, 1937-38, W. RUDOLFS (*New Jersey Stat. Bul.* 659 (1939), pp. 22, figs. 7).—In a survey of Raritan River and its principal tributaries, May 1937 to March 1938, it was shown that the natural waters of the Raritan do not change materially in chemical composition, are fairly clear, are the least mineralized in northern New Jersey, and have a low bacterial content. They are, therefore, admirably suited for industrial purposes, are fit for recreational use, and are an excellent source of potable supplies. During a 10-yr. period bacterial pollution has decreased and chemical pollution has increased, the last-named pollution appearing to come mainly from between the towns of Somerville and Bound Brook. The discharge of chemical wastes appeared to interfere with the self-purification and oxidation power of the stream, to be detrimental to fish life, and to prevent the fullest recreational use of the river. It is further noted that "discoloration and annoyance in respect to sailing and rowing craft will continue until the industrial wastes responsible are adequately treated. The bacteriological results show that the river is still unfit for swimming, but it is expected that upon completion of all sewage plants under construction the health hazard will be greatly reduced because of removal of polluting substances and chlorination of effluents discharged." The sludge and other oxygen-consuming substances removed by the treatment in sewage plants were found equivalent to 8,750 lb. of oxygen or to the addition of from 90 to 120 million gallons of clean water daily. It was indicated that intestinal bacteria will be reduced during the summer months (May-October) by 99.9 percent or more, but "until pollution from industrial sources has been alleviated, the general improvement of the river will be less than could be expected from the investment in sewage treatment plants by the various communities." A summary of the newly constructed sewage plants is presented, and the probable purification effects are indicated.

Farm drainage: Its maintenance and construction, E. W. LEHMANN and T. A. PITZEN (*Illinois Sta. Cir.* 493 (1939), pp. 40, figs. 31).—For the maintenance of best farming conditions, more than one-third of the farm lands in Illinois must be artificially drained, and the total of public and private drainage structure investment in the State amounts to about \$150,000,000. The authors warn against installation of expensive drainage systems without provision for their regular and thorough repair and efficiency maintenance. The main topics taken up in the circular cover maintenance of open channels, maintaining the tile system, planning a tile system, constructing outlet for tile system, constructing the tile lines, surface inlets and sand traps, and file maps and records. Diagrams, photographs, dimensioned working drawings of various structures, and numerical data of value in the design of drainage systems are included.

Water conduction from shallow water tables, R. E. MOORE (*Hilgardia* [*California Sta.*], 12 (1939), No. 6, pp. 333-426, figs. 20).—The pressure potential (determined directly from tensiometers placed in the soil) was found to increase in an unsaturated soil at constant moisture content with increasing temperature, and the amount of water held in the soil at a given pressure potential to decrease with increasing temperature. During periods of temperature change in a soil column in which there is a high water table, these relations cause wide variation in the rate of water uptake from a water table. Under field conditions, rapid changes in soil temperature above a water table would be accompanied by rising water tables with rising temperature, and falling water tables with falling temperature. The pressure potential (ψ) of the water films in a soil is a measure of the curvature of the films and an index of the degree to which the soil is saturated. The relation of soil permeability, K , to pressure potential was studied and curves of $K=f(\psi)$ were developed. K could also be studied as a function of P_w (moisture content) through the relationship be-

tween ψ and P_w . Permeability was a maximum at or near saturation and decreased rapidly with decreasing P_w to approximately the moisture equivalent of the soil, at which moisture content the permeability was very low and remained constant or decreased only slightly with further decreases in moisture content. At this point $\delta K/\delta \psi = 0$ (approximately). This moisture content is also approximately that of the wetted front generated as the water advanced upward through the dry soil above a water table. These two criteria, the P_w at which $\delta K/\delta \psi = 0$ and the P_w of the wetting front, are interpreted as representing the P at which the moisture films in the soil become discontinuous and at which the capillary permeability of the soil is zero.

The effect of texture upon the behavior of the soils used in the experiments here recorded produced the order of permeability for flow in the saturated soil: Sand > fine sandy loam > light clay > clay; and for unsaturated flow at $\psi = -100$ sand < fine sandy loam < light clay < clay. "If arranged in order of decreasing pressure potential at which unsaturated flow is approximately zero, the sequence obtained is: Sand > fine sandy loam > light clay > clay."

Effect of steaming on the strength of southern yellow pine, S. J. BUCKMAN and L. W. REES. (Minn. Expt. Sta.). (*Amer. Wood-Preservers' Assoc. Proc.*, 34 (1938), pp. 264-296, figs. 4).—This study was made on specimens of shortleaf and of slash pines. The trees were from Forrest County, Miss. Comparable groups of clear unseasoned sapwood specimens obtained from five different trees, each specimen being cut 1 by 1 by 34 in., were steamed for periods of time ranging from 3 to 18 hr. and at temperatures ranging from 214° to 260° F. The samples for strength tests were sawed from these specimens after they were steamed. The percentage loss in strength for each steaming period was based on control specimens, not steamed.

The data showed considerable loss in all of the strength properties investigated even at the lower temperatures and for the shorter steaming periods, except in maximum shearing strength parallel to the grain, where the loss appeared too small. The strength properties most affected by the least severe steaming were the fiber stress at the proportional limit in the static bending and compression tests. The losses due to steaming for 18 hr. at a temperature of 260° varied from 18.4 percent for modulus of elasticity to 56.5 percent for stress at the proportional limit in compression parallel to the grain. It was found that there was a recovery of one-fourth to one-half of the loss in strength due to steaming when specimens were tested at a moisture content of 12 percent, as compared with the strength of unseasoned specimens. The largest recoveries occurred in those specimens which had been least severely steamed. These recoveries, however, were not permanent and were found to depend upon the moisture content of the wood at the time it was tested. The data were used to show that the reduction in the strength of a 20-in. pole steamed for 18 hr. is about 31 percent, while the strength of a 58-in. pole steamed for 4 hr. is reduced about 5 percent. Because of this decrease in strength due to steaming, it was recommended that southern yellow pine poles be air-dried prior to preservative treatment.

Preservative treatment of fence posts (*Connecticut [New Haven] Sta. Bul.* 421 (1939), pp. 34, 35).—This report notes the success of various treatments of native woods, used to replace chestnut, with creosote, zinc chloride, etc. It is noted that wind-felled timber left by the hurricane can be so utilized.

Affinity of hydrophilic aggregate for asphaltic bitumen, H. F. WINTERKORN. (Univ. Mo.). (*Indus. and Engin. Chem.*, 30 (1938), No. 12, pp. 1362-1368, figs. 4).—By means of a wash test following various pretreatments, the author showed that the stripping resistance of bitumen-coated aggregate de-

depends upon the properties of the bitumen, the surface properties of the mineral, and the time and condition of contact between bitumen and mineral surface. Washing with aqua regia tended to improve the adhesiveness more than washing with hydrochloric acid. Samples taken from a bituminous soil stabilization project, in some sections of which resin-forming primers were used, were tested in the laboratory with the result that specimens containing aniline-furfural, high-temperature tar-furfural, and low-temperature tar-furfural admixtures showed better resistance to water than samples which did not contain these materials. "The evidence appears to show that furfural and its resinous derivatives might be destined to fill an important place in bituminous road construction."

Factors which influence the durability of concrete stave silos, D. G. MILLER. (Minn. Expt. Sta. and U. S. D. A.). (*Jour. Amer. Concrete Inst.*, 9 (1938), No. 4, pp. 381-397, figs. 15).—The author examined about 200 concrete silos in several States and obtained test data on 1,350 experimental concrete silo staves made at 9 commercial plants to determine the effect of mix or number of staves per bag, tamping (the number of tamps per stave), water: cement ratio, and aggregate grading. It is shown by results of permeability tests that the transverse strength and density of silo staves are closely related, and the inference is drawn that the greatest durability may reasonably be expected of those staves having transverse strengths upward from 140 lb. per inch of width when tested by applying the load midway between supports 24 in. apart. It is shown in the report that the 10-min. absorption of a stave, following drying to constant weight at a temperature of 240° F., is a direct measure of permeability. For strengths above 140 lb. per inch of width the quantity of water absorbed after 10 min. is between 1 and 2 percent and is fairly constant. The 10-min. absorption therefore provides a simple test for permeability of dry tamped staves, and thus makes it reasonably easy to correlate strength and density of staves as a basis for studies of durability under exposure conditions found in silos.

Drying seed cotton, F. L. GERDES, W. J. MARTIN, and C. A. BENNETT (*U. S. Dept. Agr. Leaflet 181* (1939), pp. 8, figs. 3).—A 17-floor drier at a temperature of 150° F. removed moisture from about 1 lb. per 100 lb. of seed cotton with less than 12 percent moisture to 8 lb. from cotton having 16 percent or more. The percentage removed from each of these cottons at temperatures up to 250° was only slightly greater than at 150°. This result was attributed to the relatively short exposure in the drier (15 sec.) and the fact that the relative humidity of the air heated to the higher temperatures is not appreciably lower than that at 150°. The moisture removed from lint per 100 lb. by drying for 15 sec. at 150° ranged from an average of 1.5 lb. for seed cottons below 12 percent in moisture to an average of 4 lb. for those having 16 percent or more. It increased slightly with higher drying temperatures. Actual differences in the weight of bales due to drying are not permanent. The results of a storage test show that a bale of undried (damp) cotton rapidly lost weight; that a dried bale gained slightly; and that, at the end of 10 weeks, the bales differed in weight by only 4 lb. as compared with 16 lb. at the beginning of the storage period. Fiber was not weakened by drying at 200°, but there was a slight weakening when the material was dried twice at 250°. Staple length, on an average, was preserved at 150°, but, in general, higher drying temperatures resulted in ginned lint with slightly shorter staple length. It was found better to pass wet cotton twice through a drier at 150° than once at a temperature above 200°.

Average improvements in grade of cotton (the combined influence of generally smoother preparation and occasionally brighter color and reduced leaf) result-

ing from artificial drying were greater for the cotton 1½ in. and longer than for the shorter staples. Drying at a temperature of 150° with the 17-floor drier showed benefits in grade ranging on an average from about one grade for either length group having 16 percent or more of moisture to about one-third of a grade for the longer cottons having from 8 to 11.9 percent and the shorter cottons having from 12 to 15.9 percent of moisture. The average gain in bale value was from 70 ct. for short staple to \$2.50 for long staple cotton as against an operating cost of from 5 to 30 ct. per bale for drying. It was further found that drying usually eliminates chokages and break-down and permits some increase in ginning capacity. Inexpensive cleaner-driers economically practical for the small gin have been devised.

As sources of heat, steam, engine-cooling water and engine exhaust, and furnace heating are mentioned, and the possibilities of combinations of these sources are briefly indicated.

Requirements in tobacco barn construction (*Kentucky Sta. Rpt. 1938, pt. 1, p. 53*).—Observation of the formation of temperature and humidity zones in tobacco barns indicated that it will probably be necessary to use forced air circulation in some form in order to maintain optimum conditions in all parts of such barns.

Old laying houses can be modernized, D. C. KENNARD and V. D. CHAMBERLIN (*Ohio Sta. Bmo. Bul. 198 (1939), pp. 62-64, fig. 1*).—The suggestions given are also deemed applicable to new construction.

Human and physical resources of Tennessee.—XVI, Electrical resources and development, C. E. ALLED, S. W. ATKINS, and W. E. HENDRIX (*Tenn. Agr. Col., Agr. Econ. and Rural Sociol. Dept. Monog. 64 (1937), pp. [1]-IV+264-278, figs. 7*).—It is stated that only New York State, Oregon, and Washington have more potential water power per square mile than does Tennessee. The last-named State ranks tenth, however, in developed hydroelectric power. The rapid development since construction of the first modern hydroelectric plant in the State in 1909 is outlined. The number of plants and of electric power companies has decreased more than 50 percent since 1924. Electric transmission lines were found to reach nearly all counties of Tennessee. Since 1920 Tennessee has averaged about twenty-sixth in the United States and about fifth in the Southeast in production of electricity. The annual production since 1929 has averaged slightly over one billion kilowatt-hours. In 1936, 75 percent of the electricity was produced by water power and 25 percent by fuels. The importance of fuels in producing electric power has declined considerably since 1933. The largest use of fuels is in late summer and early fall, when stream flow is usually low. The largest users are wholesale commercial customers, principally large industrial companies. Farm power ranks lowest.

AGRICULTURAL ECONOMICS

[Articles and notes on agricultural economics] (*Jour. Farm Econ., 21 (1939), No. 2, pp. 435-461, 470-478, 489-511, figs. 7*).—Articles are included on Germany's Bid for Agricultural Self Sufficiency, by B. Higgins (pp. 435-461), and Status of Agricultural Trade Unions in Holland, by S. C. Suffrin (pp. 470-478) (Ohio State Univ.); notes as follows: Intensity and Land Rent—A Reply, by D. L. MacFarlane (pp. 489-494) (Univ. Ky.) (*E. S. R., 51, p. 200*); Some Economic Aspects of University Patents, by W. H. Nicholls (pp. 494-498) (Iowa State Col.); Type of Farming Research Again, by C. L. Holmes (pp. 498-500), and Relation Between Corn and Wheat Futures, by M. Clough (pp. 500-502) (both U. S. D. A.); Agricultural Adjustment and Marketing, by H. E. Larzelere (pp. 503-507) (Mich. State Col.); and Recent Farm Loan and Real

Estate Experiences of Five Leading Life Insurance Companies, by J. H. Dickerson (pp. 507-511) (Iowa State Col.); and a correction on an article by Wells and Du Pré (p. 511) (E. S. R., 81, p. 290).

[Investigations in agricultural economics by the Kentucky Station, 1937-38] (*Kentucky Sta. Rpt. 1938, pt. 1, pp. 26-34*).—In addition to studies previously noted, general findings are reported for studies of seasonal fluctuations in Burley tobacco prices and in quality of tobacco; regional variations in farm prices of tobacco; farm organization and management of 81 farms in 1937 in southern Christian, Todd, Simpson, Warren, and Trigg Counties, and of 152 farms in 1935 and 61 of the same farms in 1937 in central and northern Robertson County; cost of raising beef calves to weaning age; land utilization in Taylor County; and farm tenancy.

[Investigations in agricultural economics by the Massachusetts Station, 1937-38] (Partly coop. U. S. D. A.). (*Massachusetts Sta. Bul. 355 (1939), pp. 6-9, 51*).—Included are some preliminary findings by C. R. Creek and M. Butler as to factors affecting income during the year ending April 1937 on 253 dairy farms in 11 counties, the labor income on 54 dairy farms selling milk on retail routes, and the farm management and practices on 3 farms in the Nashoba fruit area; and by Creek and J. E. Donley of factors affecting labor income on 71 wholesale, 34 retail, and 9 breeding poultry farms in the 7 eastern counties of the State. Findings as to duplication of distribution are reported by A. A. Brown and W. Kling in a study of milk as a public utility, and suggested solutions with and without governmental intervention are made. Findings are also reported in studies of competitive factors influencing the supply of market milk and cream in the State, by Brown and Donley; of the economic aspects of marketing fluid milk in Worcester, Mass., by Donley and C. W. Smith; and of land-use problems in Massachusetts in relation to a balanced program of land utilization, by D. Rozman.

Current Farm Economics, [April 1939] (*Oklahoma Sta., Cur. Farm Econ., 12 (1939), No. 2, pp. 33-64, figs. 4*).—In addition to the usual tables of index numbers of prices, demand deposits, and prices and purchasing power, articles are included on the agricultural situation, by the staff of the department of agricultural economics and extension specialists; the poultry and egg situation for 1939 and 1940, by M. Hill; development of cotton production in Brazil, by K. C. Davis; and some aspects of land ownership in Nowata County, by R. T. Klemme.

Foreign Agriculture, [May 1939] (*U. S. Dept. Agr., Foreign Agr. Serv., Foreign Agr., 3 (1939), No. 5, pp. 167-218, figs. 3*).—Included are articles on Southeastern Europe's Trade Increasingly Dominated by Germany, by H. Richter (pp. 169-174); Effects of the Drought and Purge on the Agriculture of the Soviet Union, by L. Volin (pp. 175-196); and Agriculture in the French Balance of Trade, by N. W. Hazen (pp. 197-215); and notes on recent developments in foreign agricultural policy as follows: Minimum-price fixing in Argentina includes part of cattle industry, Institute of Territorial Credit established in Colombia, Manitoba to regulate marketing of natural products, and Turkish tobacco legislation.

Farm tenancy in South Dakota, H. P. HANSON (*South Dakota Sta. Cir. 25 (1939), pp. [4]+26, figs. 15*).—Included among other data are tables for eastern and western South Dakota and maps showing by Federal Census period 1910-35 by counties the percentages of total farmers that were tenants, full owners, part owners, and managers, the size and value of farms by tenure groups, and the per acre value of lands and buildings in 1935.

Economic criteria for classifying nonurban land according to probable best use, D. WEEKS and H. R. JOSEPHSON. (Univ. Calif.). (*Jour. Farm Econ.,*

21 (1939), No. 2, pp. 419-434).—Using the findings in land utilization investigations in the northern Sierra Nevada foothills of California as a basis, several economic criteria for the classification of land are discussed with a view to indicating their usefulness as an economic basis for locating appropriate margins between different uses or combination of uses of land, and judging the optimum geographical limits within which given land-use policies may be applied.

Farm adjustments in Montana.—Study of area VII: Its past, present, and future, N. W. JOHNSON. (Coop. U. S. D. A. et al.). (*Montana Sta. Bul.* 367 (1939), pp. 59, figs. 6).—This is the first of a series of bulletins constituting part 2 of Bulletin 328 (E. S. R., 76, p. 708), and deals with the area included in Hill, Liberty, and Toole Counties, a dry-farming area. The physical and other features of the area, the trends in number and size of farms, acreage of crops, livestock production, etc., are discussed. The physical conditions, ownership of land, types of farming, economic condition of farming, and conditions needing change in the seven subareas of area 7 are discussed. The need for adjustments in the area, the standards for measuring adjustments, the adjustments in farm organization and practices, and problems and possible magnitude of adjustments are discussed. Appendixes describe the sources of data and methods used in the analysis.

Supplementary tables for Bulletin 367: Types of farming in Montana.—II, Major area VII: Past, present, and future. (Coop. U. S. D. A.). (*Montana Sta. Mimeog. Cir.* 10 (1938), pp. [35], fig. 1).—This supplements the bulletin noted above.

Changes in technology and labor requirements in crop production: Wheat and oats, R. B. ELWOOD, L. E. ARNOLD, D. C. SCHMUTZ, and E. G. MCKIBBEN (*Works Prog. Admin. [U. S.], Natl. Res. Proj. Rpt. A-10* (1939), pp. XV+182, figs. 36).—"Of the factors influencing the productivity of labor used in crop production, mechanization and agronomic developments are of prime importance. By the use of machines operations are performed with less labor, and agronomic discoveries tend to result in higher yields. In the sphere of small-grain production, agronomic developments during the past 25 yr. have resulted in maintaining the average yield of wheat during a period when more and more of the crop was being raised in dry areas where yields are normally low and during a period when much of the crop was raised under conditions tending to deplete soil fertility. The yielding ability of wheat grown today is, in all probability, greater than it was 25 yr. ago. The development of superior varieties will no doubt continue to be a factor in reducing per-bushel labor requirements in the future.

"In the past, however, agronomic developments have been overshadowed by mechanization. In fact, the use of machines in raising wheat is a classic example of the mechanization of agriculture. A century ago the production of an acre of wheat required nearly 60 man-hours; in 1896, with machine methods, about 9 hr. were required in the central Winter Wheat Belt; today, with the most modern machinery, it requires less than 5 hr. and in some regions not more than 2 or 3 hr. of work. Although most of the reduction in labor needs occurred prior to the period 1909-36, within that period labor requirements per acre of wheat have declined by more than 50 percent."

The economic situation facing New Jersey vegetable growers, J. W. CARNCROSS and A. G. WALLER (*New Jersey Stat. Bul.* 660 (1939), pp. 59, figs. 42).—Tables and charts present data as to acreages, yields, and values of fresh vegetables in the United States by sections and New Jersey, 1919-34, prices of vegetables, farm products and fertilizers, wholesale prices of all commodities, and farm wages and farm taxes in New Jersey 1910-37. Data were presented

regarding the business in 1937 on 25 vegetable farms in Monmouth County and 2 in Gloucester County, the trends of prices of individual vegetables in New Jersey 1910-37, the average value per acre of different vegetables in New Jersey 1925-29 and 1933-37, and the relations of size to net income from truck farms and of costs to labor income in 1937. The markets for New Jersey vegetables, changes in supplies, relation of market supply and price, and seasonal variation in prices are discussed.

The acreage of vegetables grown for sale in the United States increased 16.5 percent from 1919 to 1934, while the population increased about 20 percent. The index of prices of vegetables 1933-37 for New Jersey averaged approximately 23 percent lower than that for all farm products. For the period 1920-29 that for vegetables was 20 percent higher. The average labor income in 1937 on the 25 specialized vegetable farms in Monmouth County was —\$946. Prices of many vegetables were as low or lower than the 1910-14 average. Gross value per acre of many vegetables was much lower during the period 1933-37 than the period 1925-29. Relatively small size of business was one of the problems confronting the industry. Of the 25 specialized vegetable farms in Monmouth County studied in 1937, 10 with sales averaging approximately \$14,800 had an average labor income of \$114, while 15 with sales averaging \$2,172 had an average labor income of —\$1,653. The 12 with yields averaging 27 percent above the average for all farms had a labor income of \$553, and 13 with yields approximately 25 percent below the average had a labor income of —\$2,329.

Economic aspects of hybrid corn, A. A. DOWELL and O. B. JESNESS. (Minn. Expt. Sta.). (*Jour. Farm Econ.*, 21 (1939), No. 2, pp. 479-488).—The probable effects on acreage, production, distribution of production, costs, land values, prices, etc., are discussed.

Fruit trees in the Wenatchee-Okanogan District, Washington, W. W. RUFENER (*Washington Sta. Bul.* 369 (1939), pp. 55, figs. 19).—This bulletin presents an analysis similar to that for the Yakima Valley (E. S. R., 80, p. 260). Tables, maps, and charts show for apple, pear, apricot, peach, cherry, plum, and prune trees data as to distribution, age, varieties, etc., of trees obtained in the Tree Fruit Census of 1936.

Of the approximately 2,600,000 fruit trees in the district, about 75 percent were apples, 13 pear, 6 apricot, 3 peach, 3 cherry, and 0.6 plums and prunes. Of the apple trees 26.2 percent were less than 10 yr. of age and 46.9 percent 17 to 26 yr. old. Approximately 6 percent of the trees in 1934 in the southern part of Chelan and Douglas Counties, and 25 percent of those in the Grant County-Moses Coulee area were pulled in 1935 and 1936. The major trends in apple production have been a decline in the total number of trees, an increase in the importance of the northern part of the district, and an increased preference for Delicious varieties, particularly Red Delicious. Materially increased production of pears, apricots, peaches, and cherries is indicated by the fact that nearly 50 percent of the pear, 55 percent of the apricot, 66 percent of the peach, and 53 percent of the cherry trees were less than 10 yr. of age. Red Delicious apples, d'Anjou pears, Hale peaches, and Bing cherries have been favored by producers in the plantings during 1931-35.

Milk distribution costs of producer-distributors and subdealers in New Jersey, E. H. RINEAR (*New Jersey Stat. Bul.* 663 (1939), pp. 56, figs. 14).—Records were obtained by personal interviews covering the operation in 1936 of 63 producer-distributors in 4 markets in the northern and 3 markets in the southern part of the State, and 47 subdealers in 2 markets in the northern part. The importance of total volume of milk handled in the State, the volumes

handled by producer-distributors and subdealers, price schedules followed, and the milk control board prices and margins are discussed.

The average total investment in plant and equipment was \$3,037 for the producer-distributor and \$981 for the subdealers, being \$2.77 per 100 qt. volume for grade B producer-distributors in north Jersey and \$2.20 in south Jersey. The range and average costs per 100 qt. volume for producer-distributors and subdealers, respectively, were: Interest 9 to 18 ct., average 12 ct., and 1 to 5 ct., average 3 ct.; depreciation 9 to 35 ct., average 14 ct., and average $\frac{1}{3}$ ct.; delivery and collection (excluding labor) 71 ct. to \$1.83, average \$1, and \$1.30 to \$1.34, average \$1.33; other costs 80 ct. to \$1.95, average \$1.08, and 25 to 39 ct., average 31 ct.; and total costs (excluding labor) \$1.92 to \$3.54, average \$2.43, and \$1.60 to \$1.74, average \$1.67. Total costs of grade A producer-distributors averaged \$2.31 in north Jersey and \$2.86 in south Jersey as compared with \$2.31 and \$2.46, respectively, for grade B producer-distributors. Total hours of labor per 100 qt. volume ranged from 4.6 to 6.9, average 6.1, for the producer-distributors and from 3.6 to 3.8, average 3.8, for the subdealers. Returns from labor ranged from 70 ct. to \$1.74 per hour, average \$1.19, and from 80 to 81 ct., average 81 ct., respectively. Returns from labor averaged \$1.57 per hour for grade A producer-distributors in north Jersey and \$1.64 in south Jersey. For grade B producer-distributors the averages were 99 and 65 ct., respectively. The study showed that small distributors can have as low or lower costs than large distributors, but usually do not, and that there was a tendency for producer-distributors to use labor more efficiently when 100,000 qt. or more were sold annually.

Evolution of a plan for intra-association shifting of the capital obligations among members, H. E. ERDMAN and W. W. TAYLOR. (Univ. Calif.). (*Jour. Farm Econ.*, 21 (1939), No. 2, pp. 462-469).—This is a case study of the new features developed in the financial structure of the Poultry Producers of Central California, a successful nonstock cooperative association.

Cooperative purchasing in Washington, E. F. DUMMEYER (*Washington Sta. Bul.* 371 (1939), pp. 28).—This is a popular bulletin describing and discussing the meaning of cooperation, what constitutes a cooperative society, cooperative marketing and purchasing in the United States and the State of Washington, the future of cooperative purchasing, and cooperative purchasing in Washington of feed, petroleum products, fruit and vegetable growing and packing supplies, other side lines, groceries and general merchandise, and services.

The greatest success in cooperative purchasing in Washington has occurred where previous marketing methods involved unnecessary duplication of facilities and selling efforts; with staple commodities, which purchasers desired in large volume, and which could be standardized as to quality; where one staple or group of products assured volume of business; where expenses were kept low in relation to volume of sales, and credit was limited so there was little or no risk; where there was capable and enthusiastic leadership, good judgment in filling managerial positions, and adequate, accurate accounts kept; where there was adequate financing but no unnecessary expensive plants; where there was a system of paying patronage dividends in cash or membership interest in capital of the association; and in the case of feeds and petroleum products where the chain store method was used of combining in one organization or closely affiliated organizations wholesaling or jobbing and retailing services.

State trade barriers: Selected references, L. O. BERCAW (*U. S. Dept. Agr., Bur. Agr. Econ., Econ. Libr. List.* 1 (1939), pp. 16).—This is a mimeographed and indexed list of 63 annotated references.

Seasonal aspects of the European wheat trade, M. K. BENNETT (*Wheat Studies, Food Res. Inst. [Stanford Univ.], 15 (1939), No. 6, pp. [2]+297-335, figs. 14*).—"Overseas shipments of wheat and flour to Europe in August-December, when North American wheat usually preponderates, have ranged in the past 17 crop years from 37.4 to 44.55 percent of the crop-year shipments. A view rather widely accepted in trade circles is that the fraction of the year's total shipped in these months tends to be small when the margin between world export surpluses and world import requirements is large. Under such circumstances, it is commonly supposed that European importers tend to avoid accumulation of stocks in August-December in expectation of cheaper wheat in the winter when the Southern Hemisphere export movement is at its peak. The present study indicates that the reverse of this is true. Autumnal accumulation of import wheat stocks appears to be normal behavior of European importers in years of large margin of surpluses over requirements, mainly as the result of export pressure in the autumn. In general, August-December shipments to Europe may be expected to approximate 43.3 percent of crop-year shipments in years when margins (as calculated in this study) run larger than 250 million bushels."

Index numbers of production, prices, and income, J. I. FALCONER (*Ohio Sta. Bmo. Bul. 198 (1939), p. 70*).—The series (E. S. R., 81, p. 432) is brought down through February 1939.

Laws affecting agriculture [in North Dakota], D. G. HAY (*North Dakota Sta. Bmo. Bul., 1 (1939), No. 5, pp. 27-34*).—This is a summary of certain laws enacted by the 1939 North Dakota Legislature relating to property taxation, county government, public lands, soil conservation, livestock, marketing, cooperatives, mortgages, and education.

RURAL SOCIOLOGY

Washington country weekly newspapers, their distribution and characteristics, 1902-1938, C. F. REUSS (*Washington Sta. Bul. 373 (1939), pp. 30, figs. 7*).—Information included in N. W. Ayer and Son's Directory of Newspapers and Periodicals for all weekly newspapers of the State except those published in Seattle, Tacoma, and Spokane, for the years 1902, 1910, 1920, 1930, and 1938, is analyzed to show for the western, central, and eastern divisions of the State the trends in numbers of newspapers, population of towns, business units per town, and characteristics of the newspapers (day of publication, number of columns, politics, subscription price, and circulation). The causes of the disappearance of newspapers and the characteristics of those disappearing are discussed.

The number of weekly newspapers increased from 159 in 1902 to 252 in 1914 and decreased from 250 in 1918 to 180 in 1921, and was 185 in 1938. Since 1910 the proportion of papers in villages of less than 1,000 population increased. In 1930 and 1938 80 percent of the towns and cities of 1,000 or more population and 50 percent of the villages and towns of from 500 to 999 population had a weekly newspaper. The average number of persons per newspaper was 2,282 in 1902 and 5,476 in 1938. The number of persons per copy issued increased from 2.9 to 4.8. From 1902 to 1930 the proportion of newspapers having a circulation of less than 1,000 copies decreased and that of papers with a circulation of from 1,500 to 2,499 copies increased. In 1938 there was an increase in the proportion of papers of small circulation and a decrease in those with circulations over 1,500. Average circulation increased 47 percent from 1902 to 1938. By

1938, 125 of the 236 weekly newspapers published in 1910 and 46 of 194 published in 1930 had disappeared. The analysis indicated that the greatest chance for survival for a weekly newspaper is for one published on Thursday or Friday in a town of from 1,000 to 3,999 population and with a circulation of from 500 or 750 to 2,000 copies, and where the paper is more strictly a newspaper than an adjunct to a job printing shop or a legal publications sheet.

A portrait of the farm family in central New York State, H. W. BEERS. (Rutgers Univ.). (*Amer. Sociol. Rev.*, 2 (1937), No. 5, pp. 591-600).—The portrait of today's farm family in central New York is a modification of old patterns, a partial acceptance of new patterns. It is smaller than the pioneer family, yet it is still among our chief sources of population increase. The rural social organization of the area is no longer familistic, but it is at least "semifamilistic." There is a definite heritage of paternal dominance, but its outlines become progressively more dim. Specialization and education have affected the division of labor, but shared work and shared leisure are still formative of the family pattern. Propinquity continues to foster solidarity, resisting the centrifugal effects of urbanization. Definite democratization in the changes of role and status accelerates with the advance of business efficiency and industrialization in agriculture. Both rate and direction of future change in the farm family pattern are, therefore, as likely to depend upon larger economic and social influences affecting agriculture as upon the dictation of tradition.

It is deemed significant that the family pattern of these farm folk is so widely valued today. As an accepted design for living, it is a stated or implied goal of those current governmental efforts at agricultural adjustment which propose to make the family farm more general and more secure.

Farm population (Kentucky Sta. Rpt. 1938, pt. 1, pp. 34, 35).—An analysis of Federal census data as to rate of natural increase, race, and net migration in Kentucky is briefly noted.

Research in causes of variations in fertility: Social psychological aspects, L. S. CORRELL, JR. (Cornell Univ.). (*Amer. Sociol. Rev.*, 2 (1937), No. 5, pp. 678-685).—Negative relations were found between fertility rates and the degree of urbanization of a given population, the position in the social-economic scale as indexed by income and occupational status, the occupational rank, educational achievement, and between fertility rates and the indices of social-economic emancipation of women.

Rural relief trends in Wisconsin from 1934 to 1937, G. W. HILL and R. A. SMITH (Madison: Univ. Wis. Press, 1939, pp. [5]+57, figs. [6]).—This report discusses the rural families on relief as to residence, age characteristics, size of family, occupational training, employability, and relief costs per family. Included also is a discussion of the trend in costs and cases.

AGRICULTURAL AND HOME ECONOMICS EDUCATION

Proceedings of the Association of Land-Grant Colleges and Universities (*Assoc. Land-Grant Colls. and Univ. Proc.*, 52 (1938), pp. [I]+V+357).—This is the report of the meeting held at Chicago November 14-16, 1938 (E. S. R., 80, pp. 1, 143, 145). It includes the papers and discussions presented at the general sessions, and the sections on agriculture, resident teaching, experiment stations, extension work, engineering, and home economics; the minutes of the executive body; reports of committees; and lists of officers and committees for the succeeding year. Memorial tributes to H. W. Mumford, L. D. Coffman, and J. R. Ricks are also included.

FOODS—HUMAN NUTRITION

[Food and nutrition studies of the Massachusetts Station] (*Massachusetts Sta. Bul.* 355 (1939), pp. 26, 27, 36-38, 38, 70-72, 73, 74, 75-77).—Included in this progress report are summaries of studies, several of which represent a continuation of earlier work (E. S. R., 79, p. 561), by J. E. Fuller and W. B. Esselen, Jr., on the influence of calcium salts on the fecal flora of albino rats and on the influence of bacteria on the oxidation of ascorbic acid (vitamin C) (pp. 26, 27); by G. R. Vitagliano and Fuller on gum production by *Aerobacter aerogenes* (p. 27); by Fuller and E. R. Higgins on the relationship of onion juice to bacterial growth (p. 27); by M. E. Freeman and W. S. Ritchie on chemical changes in cooking of vegetables (pp. 36, 37); by Ritchie on changes in meat stored in frozen condition (pp. 37, 38); by W. Mueller and Ritchie on the content of lead in samples of chocolate and cocoa (p. 38); by H. S. Mitchell, G. M. Cook, and O. A. Merriam on the cause and control of nutritional cataract (pp. 70-72) (E. S. R., 80, p. 839); by Mitchell, M. Goldfaden, and G. Hadro on the relation of iodine or other minerals to the prevention of cholesterol-induced atherosclerosis in rabbits (p. 73); by O. R. Fellers, J. A. Clague, and A. S. Levine on methods of preserving apples (p. 74); by Esselen and Fellers on the effects of relatively large amounts of vitamin B₁ and B₂ in addition to optimum amounts of vitamin C on the cure of scurvy in guinea pigs (pp. 75, 76); by Levine, M. G. O'Connor, and Fellers on the preservative effects of acetic and benzoic acids (p. 76); by Fellers, Levine, and Esselen on the preservation and food value of cranberries (pp. 76, 77); by J. Novick and Fellers on currant juice and jelly (p. 77); and by M. E. Lyons and Fellers on the vitamin C content of potatoes (p. 77).

[Food and nutrition studies by the Wyoming Station] (*Wyoming Sta. Rpt.* 1938, pp. 21-23).—This progress report (E. S. R., 79, p. 129) summarizes studies on the effect of age and method of storage on the activity of three types of bakers' yeast, the calibration of pressure cooker gages for the high altitude of the station, doughnut cooking at high altitudes, the vitamin C content of potatoes in storage as determined by titration, and the culinary qualities of several varieties of potatoes.

Adhesion of potato-tuber cells as influenced by temperature, C. J. PERSONIUS and P. F. SHARP. (Cornell Univ.). (*Food Res.*, 3 (1938), No. 5, pp. 513-524, figs. 4).—In this and the following paper some phases are reported of a study of the effect of heat on potato-tuber tissues in an effort to develop satisfactory objective tests for potato mealiness.

Tensile strength of slices of potato tissue was determined by a technic and apparatus developed for the test. Considerable attention was given to the method of cutting test pieces of the potato tissue. The size of the tuber from which the sections were cut, the plane of cut, and the weight and extensibility of the section under stress did not affect the tensile strength, nor was any relationship noted between the tensile strength of the raw tuber and the variety or texture. Higher tensile-strength values were obtained from inner medullae than outer medullae. Consequently a definite sampling method had to be worked out in order to obtain comparable results for tensile-strength values.

Tubers cooked to the point of being readily mashed with a fork gave tensile strengths of 0.7 kg. per square centimeter or less, with a customary value of 0.5 kg. When potatoes were cooked at different temperatures until done, or nearly done, no appreciable reduction in tensile strength occurred during 48 hr. at temperatures of 50° C. (122° F.) or lower. At higher temperatures the

rate of reduction in tensile strength increased with the temperature to a relatively constant value. When these constant values were plotted against the temperature, it became evident that the weakening of the cement wall takes place to a certain extent at any temperature between 45° and 75°. At a given temperature the weakening goes to a certain point and stops, after which it is only by increasing the temperature that the process can continue. The complete weakening of the cement substance can be brought about at 75° with higher temperatures increasing the speed of completion of the reaction. As this temperature is below the gelatinization temperature of the starch, it is concluded that cell separation and gelatinization are independent. No difference was noted between soggy and mealy potatoes in the adhesion of the cells of the raw or cooked tissue.

Permeability of potato-tuber tissue as influenced by heat, C. J. PERSONIUS and P. F. SHARP. (Cornell Univ.). (*Food Res.*, 3 (1938), No. 5, pp. 525-538, figs. 8).—The possibility of a relation between the loss of adhesion between the cells, starch swelling, and alterations in the permeability of the potato-tuber tissue was investigated, with alterations in the electrical resistance of sections of the tissue used as an indication of the changes in tissue permeability and as a method of investigating the possibility that in the final stages of cooking separation of the tissue cells might occur with the formation of intercellular air spaces. A special conductivity cell devised for the measurement is described and illustrated by a diagram, and the data obtained in its use are presented in curves obtained by plotting the logarithm of the resistance of the sample against the internal temperature.

No significant difference in the effect of heat on the permeability of the tissue of soggy and mealy potatoes was noted. In both, the resistance decreased slowly during the first 8 or 10 min. of heating, while the internal temperature of a sample was increased to about 60° C.; but in the next 2 or 3 min., during a temperature rise of about 10°, the resistance decreased very rapidly and then more slowly within the remaining 15 or 20 min., until the internal temperature reached approximately 100°. The temperature range in which the change in permeability was most abrupt was the same as that at which most of the starch of the potato began to swell or became gelatinized. The increase in resistance of starch suspensions at the point of gelatinization or swell was masked in the potato tissue by the rapid increase in permeability of the tissues at this point. Failure of the resistance to increase appreciably at the end of the cooking period is thought to indicate that little or no formation of intercellular air spaces occurs in potatoes during cooking.

Passage of a 110-v. alternating current through potato sections markedly decreased the resistance at temperatures considerably below the minimum temperature of 60°, at which the resistance was first lowered in ordinary cooking. This was attributed to the uniform resistance offered by the tissues with resulting localized heating. This method of applying heat locally to specific parts of the tissue is thought to open up many possibilities for investigation.

Bacteria, enzymes, and vitamins—indices of quality in frozen vegetables, D. K. TRESSLER. (N. Y. State Expt. Sta.). (*Refrig. Engin.*, 36 (1938), No. 5, pp. 319-321).—Based on the author's extensive investigations of frozen vegetables, three criteria for judging the quality of most frozen vegetables are proposed, namely, bacterial count, catalase and peroxidase tests, and determination of ascorbic acid content.

A bacterial count under 80,000 per gram shows that the product was blanched at a high enough temperature to kill practically all of the bacteria on the surface of the fresh vegetable, that the blanched product was quickly and

adequately cooled in water free from gross contamination and kept cool through the preparation period, was packed in clean packages in a clean and sanitary plant and frozen rapidly to prevent the multiplication of bacteria during this operation, and that the frozen vegetable had not been allowed to thaw at any time during storage, transportation, or marketing. With careless handling at any time from preparation to marketing, the bacterial count would be at least 100,000 or possibly 200,000 or more per gram.

The absence of the enzymes catalase and peroxidase indicates that the vegetable was sufficiently blanched not to develop off-flavors or lose color during storage at 0° F. or lower for a period of 1 yr. If either the catalase or peroxidase activity exceeds 1 percent of that of the unblanched vegetable, the product has probably not been blanched sufficiently and should immediately be placed in storage at the lowest available temperature. It is noted that the catalase and peroxidase tests are also of great help in determining the proper blanching time for novel vegetable products.

A normal or high vitamin C content for the vegetable in question is considered good evidence that the vegetable was not overmature at the time of harvesting and was properly handled during the operation preparatory to freezing, and that the frozen product was stored in a sufficiently low temperature—0° or lower. Values considered normal for the vitamin C content of certain carefully handled frozen vegetables are peas 0.17 mg. ascorbic acid per gram, lima beans 0.18, spinach 0.50, broccoli 0.80, sweet corn 0.08, and snap beans 0.14 mg. ascorbic acid per gram.

The preparation of rhubarb juice, H. G. BEATTIE and C. S. PEDERSON (*New York State Sta. Ctr.* 185 (1939), pp. 4).—The method described yields a cloudy full-bodied juice which is said to contain the full aroma and flavor of the rhubarb better than the clear juice obtained by the method previously noted (*E. S. R.*, 75, p. 718). The principal difference is the omission of the clarification procedure with a pectin enzyme preparation. Oxalates are removed as in the earlier method, and the product is pasteurized, preferably in a flash pasteurizer, as described in Circular 181 (*E. S. R.*, 79, p. 533).

Health values of pickles and kraut, C. R. FILLERS. (Mass. State Col.). (*Fruit Prod. Jour. and Amer. Vinegar Indus.*, 18 (1939), No. 9, pp. 276, 283; also in *Canner*, 88 (1939), No. 20, p. 14).—This is an abstract of a paper presented at the Technical School for Pickle and Kraut Packers. Vitamin C, lactic acid, and salt are emphasized as the most important constituents of both sauerkraut and genuine dill pickles. Tank kraut is said to contain twice as much vitamin C per unit volume as canned tomato or pineapple juices. Processing and dilution with salt brine reduce the vitamin C values. Genuine dill pickles contain only about 10 percent as much vitamin C as kraut. Their laxative effect is thought to be associated with the pectin present and possibly to some extent with lactic acid.

Household storage of fruits and vegetables, R. E. ROBINSON (*Canada Dept. Agr. Pub.* 632 (1938), pp. 8).—Directions applicable to Canadian conditions are given for the home construction of a storage room for fruits and vegetables and the selection of material suitable for storage, with specific directions for apples, potatoes, onions, cabbage, cauliflower, celery, squash and pumpkin, tomatoes, several root vegetables, and sweetpotatoes.

Survey of national nutrition policies, 1937-38 (*Genève (Geneva)*: League of Nations, *Econ. and Financ.*, 1938, II A 25, pp. 120).—This report is based chiefly on the reports furnished by various governments during 1938 to the League of Nations concerning certain aspects of national nutrition policies and

on the discussion of representatives of national nutrition committees at a conference held in Geneva in October 1938. The first two chapters give a brief account of the work of the Technical Commission on Nutrition of the League since 1936 and the scope and functions of the national nutrition committees organized at the recommendation of the "mixed committee." The remaining six chapters constitute an analysis of the types of activities in which these national committees are engaged and an indication of the lines along which certain of them are developing. The greatest emphasis is given to dietary surveys and their results in certain countries. Next in importance appears to be the action taken in various countries with a view to improving nutritional standards. Attention is also given, although to a less extent, to special research problems, economic aspects of the nutrition problem, and education and publicity. A list of the countries from which reports on nutrition progress were received and summaries of the composition, procedure, and terms of reference of the national nutrition committees are given as appendixes.

Nutrition of the Union population, E. H. CLUVER (*Jour. Roy. Sanit. Inst.*, 39 (1938), No. 2, pp 99-107).—In this paper, presented before the South African Health Congress held at Johannesburg February 14-19, 1938, data are presented from a study conducted by the South African Office of Census and Statistics on the food expenditures of European families in certain urban areas of the Union. The figures reported include the consumption per man unit (international scale) per month of different classes of food according to certain income categories and the relative consumption of the same items in the three income categories up to £175, £325-£400, and £525-£600.

In terms of the values for the lowest income group as 100 percent, the values increased for the other two groups in the items bacon, eggs, fresh milk, cheese, fresh fish, vegetables and fruits, butter, jams and sirups, and fresh meat and decreased in the items potatoes, oatmeal, rice and corn meal, sugar, bread and flour, tea and coffee, and condensed milk. The extent of increase over the basal decreased in the order named from bacon with values of 1,830 and 2,230 percent to meat with values of 112 and 112 percent, respectively, for the upper two income groups. Of the food items showing decreases with increased incomes, the range was from potatoes with values of 98 and 92 percent to condensed milk with values of 42 and 15 percent, respectively. None of the dietaries fell below 3,000 calories per man unit. The protein averaged 98 gm. per man unit for the low income group and 132 gm. for the highest income group. In both 60 gm. came from vegetable sources. In the two lowest income groups calcium fell to 0.49 gm. per man unit.

It is emphasized that these figures are for European families with definite incomes and that the situation was probably much worse in the native population. As an illustration of an extreme example, reference is made to measures which have to be taken to prevent the rapid development of scurvy in the native mine workers who arrive for work in apparently satisfactory health. The explanation is that a large proportion of the native population is in a subscorbutic state, with no reserves of vitamin C. Definite symptoms arise only when muscular work is undertaken. The same situation is thought to be true with regard to pellagra, which is very apt to develop when the naturally indolent natives are forced to work, as in prisons.

Nutrition studies (Connecticut [New Haven] Sta. Bul. 421 (1939), pp. 18, 19).—Progress is reported on a study of the requirement of calcium and phosphorus for skeletal development in rats and of the utilization of calcium from green leaves. A completed study of the effect on young rats of intraperitoneal injection of thymus extract is noted with negative results as regards stimulation of growth and development.

The scope of investigations in nutrition in the experiment station, D. KNOWLES (*North Dakota Sta. Bimo. Bul.*, 1 (1939), No. 5, pp. 19, 20).—This is a general discussion of the relation to State problems of the various projects constituting the research program in nutrition at the station.

A long-time study of nitrogen, calcium, and phosphorus metabolism on a low-protein diet, B. L. KUNERTH and M. S. PITTMAN. (*Kans. Expt. Sta.*). (*Jour. Nutr.*, 17 (1939), No. 2, pp. 161-173).—A contribution to the problem of the necessary length of time for metabolism studies is presented in this and the following paper, which give the results of nitrogen, calcium, and phosphorus balance studies in a series of 15 consecutive 3-day tests on low- and medium-protein diets.

In this study, three young women serving as subjects subsisted on a constant low-protein diet in which ground beef round furnished 85 percent of the nitrogen of an allowance planned to provide 75 percent of the protein requirements of the subjects. The diets also furnished calcium at a level of 92 percent and phosphorus at a level of 97 percent of the commonly accepted standards of 0.68 and 1.32 gm., respectively, per 70 kg. body weight. All of the subjects showed considerable variation in the retention of nitrogen, calcium, and phosphorus from period to period, with no definite cyclic tendency. Two of the subjects were in positive nitrogen balance throughout the 15 periods. The other, although having an average balance close to equilibrium, was decidedly negative in 2 periods and slightly so in 2 other periods. Two of the subjects were in positive calcium balance in only 2 and the other in 3 of the 15 periods. The phosphorus balance was negative in 9, 10, and 10 periods of the 3 subjects. There were also variations from period to period in the coefficients of digestibility and in the total urinary acid. Two menstrual periods for each subject occurred during the study. In 4 of the 6 periods, nitrogen and calcium appeared to be retained in amounts above the average and in 1 below. Phosphorus was retained in amounts above the average in half of the periods and below in the other half. The authors conclude that "measurement of the utilization of nitrogen, calcium, and phosphorus in young women subjects on moderately low-protein diets requires a long-time consecutive balance study, the length of time probably depending on the subject."

A long-time study of nitrogen, calcium, and phosphorus metabolism on a medium-protein diet, M. S. PITTMAN and B. L. KUNERTH. (*Kans. Expt. Sta.*). (*Jour. Nutr.*, 17 (1939), No. 2, pp. 175-185).—This study was conducted along similar lines to the one noted above and with the same three subjects and an additional one, the only difference in set-up being an increase in the protein to 1.2 gm. daily, 87.7 percent of which came from beef. This medium-protein diet did not eradicate the tendency to variation in the retention of nitrogen, calcium, and phosphorus observed on the low-protein diet. Balances for nitrogen and phosphorus were in all cases positive, but none of the subjects was in positive calcium balance although the retentions were improved over those on the low-protein diet.

Nutritive value for growth of some proteins of fishery products, W. B. LANHAM, JR., and J. M. LEMON (*Food Res.*, 3 (1938), No. 5, pp. 549-553).—The fish and beef proteins used in this comparative study were prepared by successive extractions of the ground product with acetone, followed by continuous extraction with acetone for 14 hr. The dried and ground product was fed to young rats at a 9-percent level in a diet consisting otherwise of butterfat 8, Osborne and Mendel salt mixture plus a trace of copper and zinc 4, a commercial vitamin concentrate from milk 4, alcoholic extract of wheat embryo 10, cod-liver oil 2, and dextrin to make 100 parts by weight. The diets were fed *ad libitum* over a period of 10 weeks to rats of an initial weight of about 50

gm., and the gains in weight were recalculated for differences in protein intake by the Fisher method of covariant analysis as used by Titus and Harshaw (E. S. R., 73, p. 366). As thus adjusted and the oyster protein given a growth-promoting value of 100, the other proteins fell roughly into three groups, with pilchard, red snapper, shrimp, and Boston mackerel as 90; shad, cod, croaker, and silver salmon as 80; and beef as 63.

Dextrose in the food industries and its health status, C. R. FELLERS. (Mass. Expt. Sta.). (*Amer. Jour. Pub. Health*, 29 (1939), No. 2, pp. 135-138).—This review of the physical, chemical, and physiological properties of dextrose, or refined corn sugar, its present use in the food industries, and its hygienic aspects closes with the statement that "refined dextrose as marketed today in the United States presents no important public health problems." A list of 23 references to the literature is appended.

The influence of hydrogenation and oxidation of fats upon their rate of absorption, M. H. IRWIN, J. WEBER, H. STEENBOCK, and T. M. GODFREY. (Wis. Expt. Sta.). (*Amer. Jour. Physiol.*, 124 (1938), No. 3, pp. 800-803).—Following the technic described in a previous report (E. S. R., 77, p. 132), the authors have determined the rate of absorption in rats of a vegetable oil hydrogenated to iodine numbers ranging from 44.7 to 108.3 and melting points ranging from below to well above body temperature (from 10° to 49° C.). Oxidized fats were also tested similarly to determine the effect of rancidity upon the rate of absorption. Variations below body temperature in the melting point of the hydrogenated fats had no effect upon the rate of absorption, but as the melting point increased above body temperature the rate of absorption showed a slight decrease. The rate of absorption of hydrogenated fats was found to vary inversely with the degree of oxidation.

The availability of iron in various foods, L. ASCHAM, M. SPEERS, and D. MADDOX. (Ga. Expt. Sta.). (*Jour. Nutr.*, 16 (1938), No. 5, pp. 425-436).—Certain foods were tested for available iron by the biological method of hemoglobin regeneration in rats made anemic by a milk diet supplemented with copper and by the chemical method of determining ionizable iron with α,α -dipyridyl, following the modified technic of Shackleton and McCance.⁴ Arranged in decreasing order of percentage of total iron in ionizable form as determined chemically, the values obtained for the material air-dried at 60°-65° C. and ground to pass through a 40-mesh sieve were mustard greens with 95 percent of the total iron in ionizable form; turnip greens and kale 75 each; spinach 70; leaf and head lettuce, tendergreen, and collards 60; and blackeyed peas (cooked before drying) 55 percent. When fed to anemic rats at the same level of ionizable iron, 0.3 mg. daily, or supplemented with FeCl_3 to give a total of 0.3 mg. of iron daily, the order of effectiveness proved to be blackeyed peas and spinach, turnip greens and kale, collards and mustard, head lettuce, and least effective tendergreen and leaf lettuce. Canned collards and canned turnip greens, with both leaves and liquid present in proportional amounts, proved more effective in hemoglobin regenerating properties than the dried materials fed in amounts furnishing the same quantity of ionizable iron.

The suggestion of Smith and Otis (E. S. R., 78, p. 282) that the discrepancies between ionizable and available iron contents of certain foods may be due to a relatively high roughage content did not appear to apply, for Cellufloer additions to the milk-iron diet were without effect. The authors conclude that "whatever the factor or factors influencing the utilization of iron, the value for the ionizable iron content of a food does not appear to be a reliable measure of the iron which is available to the body for hemoglobin production."

⁴ *Biochem. Jour.*, 30 (1936), No. 4, pp. 582-591.

The metabolism and retention of lead in growing and adult rats, J. B. SHIELDS, H. H. MITCHELL, and W. A. RUTH. (Univ. Ill.). (*Jour. Indus. Hyg. and Toxicol.*, 21 (1939), No. 1, pp. 7-23).—Following a discussion of the problems which have arisen in connection with the use of lead arsenate sprays to control insect pests on fruits and vegetables and washing solutions to remove the spray residue, particularly the question of a safe but practical tolerance for lead, a study is reported in which data were obtained in a series of experiments planned to determine the relationship between the lead content of the diet and the appetite, growth (or maintenance), and retention of lead in the bodies of rats at different periods of growth. The paired feeding method was used throughout, with one of the animals in each pair receiving no lead and the other lead administered as PbHAsO_4 in doses consisting of multiples or simple fractions of 26.7 mg. per kilogram of the ration, equivalent to 16 mg. of lead. Three different rations of low but determined content of lead were used in the course of the investigation. The dithizone color method, as modified by Clifford and Wichmann (E. S. R., 76, p. 150), was used for the determination of lead in the food and the carcasses of the rats. In a comparison of the effects of lead on growth, appetite, and retention of lead, 15 paired feeding experiments involving 240 rats were conducted. In 6 of these, young rats weighing about 50 gm. at the beginning of the experiment; in 5, partially grown animals weighing from 150 to 200 gm.; and in 4, mature rats weighing from 250 to 360 gm. were used.

Growth of the young rats and maintenance of weight in the mature rats were not impaired by concentrations of lead as high as 144 p. p. m. (the highest level tested) during periods of from 8 to 17 weeks. There was likewise no appreciable effect on health and appetite. The retentions of lead varied with the age of the animal. During the period of rapid growth there was evidence of retention at such low levels of intake as 2 p. p. m. of dry food. With increased dosage the retention increased in a parallel fashion. The animals in the later stages of growth and the mature animals did not show significant retention of lead until a certain critical concentration in the food had been reached at between 32 and 48 mg. per kilogram of dry food. The final concentration of lead in the bodies could not be raised above 9 to 9.5 p. p. m. in these two groups, but was raised to two or three times this value in young rats. The accumulated stores of lead in the young animals were shown to be much more stable than the stores accumulated after maturity. This is attributed to the fact that in the young animals the greater part of the lead is found in the large shaft of the bone, where it would be held tenaciously; while in the older, full-grown animals the store is entirely confined to the trabeculae, from which it is readily mobilized by the same agents which mobilize calcium. Absorption and digestion experiments conducted in smaller groups of animals indicated that lead is not absorbed from the stomach but is absorbed increasingly throughout the small intestine and possibly to the same extent in the cecum and colon. Most of the lead excreted from the body during the period of lead feeding was accounted for in the feces. On a ration containing 50 p. p. m. of lead, only about 10 percent of the excreted lead appeared in the urine.

Further studies on zinc deficiency in rats, E. HOVE, C. A. ELVEHJEM, and E. B. HAER. (Wis. Expt. Sta.). (*Amer. Jour. Physiol.*, 124 (1938), No. 3, pp. 750-758, figs. 2).—A new basal ration for the study of zinc deficiency in rats which permits better growth when zinc is added than the one used in earlier studies (E. S. R., 78, p. 569) is described, and analyses of tissues or whole carcasses of zinc-deficient rats and controls with added zinc are reported. The chief difference in the diet is the use of a liver product extracted with dithizone to remove the zinc in place of the milk serum of the previous study. On this

new diet the total daily intake of zinc of the male rats used in the experiment amounted to only about 7 μ g. However, the ration was still not sufficiently low in zinc to bring about any marked reduction in the concentration of zinc in the soft tissues from that in control rats receiving 100 μ g. of zinc daily. There was a very slightly higher concentration in the zinc of the livers of the controls and a marked difference in the bones and teeth, suggesting that the lower concentration in the animals on a deficient diet represents an attempt to mobilize zinc stores in order to maintain an essential concentration in the soft, cellular tissues. Aside from a greatly retarded growth rate, no definite symptoms were observed in zinc-deficient animals. Occasionally there was a slight reddening and incrustation around the eyes, nose, and feet, explained as well as the denuding and graying observed in the earlier study as being due either to slower intestinal absorption or increased requirement of this factor by the body cells. Pancreatic enzymes, especially proteinase and amylase, were shown to have a lessened activity in the zinc-deficient rats, but this is thought to be a secondary effect related to a general state of metabolic debility.

Diet and rate of depletion of hepatic vitamin A, E. J. LEASE and H. STEENBOCK. (Wis. Expt. Sta.). (*Jour. Nutr.*, 17 (1939), No. 1, pp. 85-90).—In continuation of the general investigation of the factors affecting vitamin A storage, experiments following the general plan noted previously (E. S. R., 81, p. 453) were carried out to determine the effect of high-, low-, and rancid-fat rations and of the rapid depletion of excess fat from the livers by the use of choline on young rats with uniform reserves of vitamin A produced by giving 1,500 blue units of the vitamin as halibut-liver oil daily for 4 days. Analyses of the livers of a few animals from each group after 14, 28, and 56 days of depletion showed no significant difference in vitamin A stores of rats which had been fed 30 percent of moderately rancid lard and the same amount of fresh lard. A similar comparison with older rats of fresh and very rancid lard again showed similar depletion rates. There was also no difference in the depletion of vitamin A reserves in young rats which had been on high- as compared with low-fat diets and in those whose liver fat had been depleted by the use of choline and those not receiving choline.

The biological value of carotene in various fats, E. J. and J. G. LEASE, H. STEENBOCK, and C. A. BAUMANN. (Wis. Expt. Sta.). (*Jour. Nutr.*, 17 (1939), No. 1, pp. 91-102).—The effect of various fats as solvents for carotene and vitamin A on the storage of vitamin A in the livers of young rats was tested by the same general methods noted above. Tests were also made of the same fats on growth-promoting properties of carotene and vitamin A dissolved in them and on their ability to cure ophthalmia. The possible destructive effect of the fats on both carotene and vitamin A was tested, and where destruction was shown to have taken place the amounts of the fats were adjusted so that equal quantities of carotene and vitamin A were fed. Under these conditions and with excessive amounts of carotene or vitamin A, no marked differences in storage were obtained with lard, soybean oil, cottonseed oil, devitaminized butterfat, and a hydrogenated vegetable fat as the solvents. Approximately equal growth responses were obtained with 1 μ g. daily of carotene dissolved in cottonseed oil, soybean oil, lard, decolorized butterfat, coconut oil, or crude peanut oil. Growth was inferior when the solvent was triolein, linseed oil, or "refined" peanut oil, but the rate of cure of ophthalmia was essentially the same on all of the oils.

Changes in fat, carbohydrate, and protein appetite in vitamin B deficiency, C. P. RICHTER, L. E. HOLT, JR., B. BARELARE, JR., and C. D. HAWKES (*Amer. Jour. Physiol.*, 124 (1938), No. 3, pp. 596-602, figs. 3).—The self-selection method has been applied to determine if the recognized disturbance in car-

bohydrate metabolism and the more efficient fat metabolism in rats deprived of vitamin B (complex) are reflected in the animals' appetites and if there are any alterations in the protein appetites which might suggest abnormal protein utilization. Nine rats on an adequate self-selection diet were deprived of vitamin B (complex) by the removal of yeast from the diet, and records were kept of their consumption of the different food items, which consisted of sucrose and casein (autoclaved and purified) and olive oil, cod-liver oil, 3 percent sodium chloride, 2.4 percent calcium lactate, and water in inverted drinking bottles. With the development of the deficiency state in about 30 days, the rats showed a marked aversion to carbohydrates and proteins and a craving for fat. The average daily protein intake decreased from 26 to 5 calories percent, carbohydrate intake decreased from 51 to 11, and the fat intake increased from 23 to 84 calories percent. When yeast was again supplied, the animals ate large quantities of it, and the intake of fat decreased and that of carbohydrate and protein increased. The aversion toward protein is thought to suggest a disturbance of protein utilization which has not yet been detected by biochemical methods.

Deficiency of vitamin B₁ in hookworm anaemia, A. MCKENZIE (*Lancet* [London], 1939, I, No. 20, pp. 1143-1145, fig. 1).—Two cases of hookworm anemia in male African natives were rapidly cured of edema by treatment with vitamin B₁ after treatment with iron and a generous diet had been without effect. In each case the administration of vitamin B₁ in the form of 2 or 4 mg. of betaxin was followed by increased diuresis. The results of the treatment are thought to suggest "that the edema which accompanies hookworm anemia is due to a deficiency of vitamin B₁, which is in turn due most probably to loss of vitamins in the blood extracted from the host by the hookworm."

Nicotinic acid and prevention of nutritional panmyelophthisis in rats, P. GRÖBER (*Soc. Expt. Biol. and Med. Proc.*, 37 (1938), No. 4, pp. 732-734).—In continuation of the study noted previously (*E. S. R.*, 79, p. 713), the author presents a preliminary report of an experiment conducted on rats receiving the vitamin B₆-deficient diet supplemented by nicotinic acid. During the first 8 weeks of the experimental period 20 rats died from panmyelophthisis. Upon the addition of the nicotinic acid supplement the panmyelophthisis was completely suppressed, and no animal died during the remaining 8 weeks on the experiment.

The effect of hyperthyroidism upon the metabolism of vitamin C, R. A. LEWIS (*Bul. Johns Hopkins Hosp.*, 62 (1938), No. 1, pp. 31-40, figs. 6) — A study of the vitamin C excretion of five hyperthyroid patients on a constant diet before and after subtotal thyroidectomy is reported, with the conclusion that the urinary excretion of vitamin C is greatly reduced in hyperthyroidism even when the intake is very high. In all but one of the patients excretion before thyroidectomy was in the range observed in scurvy, and following the operation the excretion rose in all patients, reaching normal values in all but one case.

Relation of vitamin D and mineral deficiencies to dental caries, G. F. TAYLOR and C. D. M. DAY (*Brit. Med. Jour.*, No. 4087 (1939), pp. 919-921).—Examination of the teeth of 10 children with severe clinical rickets, radiologically confirmed, in the Kangra District of the Punjab of India showed a very low incidence of dental caries and of gross hypoplasia. The teeth and jaws were well formed. The diets of the children were definitely deficient in minerals and vitamin D, consisting largely of carbohydrates with relatively small portions of proteins and fat. Meats and fruit were almost entirely absent, and milk and vegetables were consumed in very small quantities. Sugar was rarely eaten, the carbohydrates consisting chiefly of rice and chapatti, made from unmilled wheat ground in the home. The low incidence of caries together with the physical

nature of the food is thought to lend support to the detergent diet theory of caries prevention.

Present status of dental caries in relation to nutrition, N. SIMMONDS (*Amer. Jour. Pub. Health*, 28 (1938), No. 12, pp. 1381-1387).—This discussion and interpretation of the present somewhat conflicting views as to the etiology of dental caries emphasizes the relation of sweet foods to this condition. Two practical suggestions for the prevention of dental caries are given as follows: "(1) If an individual is susceptible to tooth decay, he should reduce his intake of all sweet foods to a minimum. In this way he will keep the flora of his mouth low in those organisms known to be acid formers. Starches and fats should be his main energy foods. (2) In addition to keeping the intake of sweet foods low, each person should plan his diet so that all factors, including vitamin D, are present in abundance."

Possible effects of vitamin K on prothrombin and clotting time in newly-born infants, W. W. WADDELL, JR., D. GUERREY, III, W. E. BRAY, and O. R. KILLEY (*Soc. Expt. Biol. and Med. Proc.*, 40 (1939), No. 3, pp. 432-434).—In a preliminary note, the authors report that the oral administration of 2 cc. of a concentrate rich in vitamin K to two female infants reduced the abnormally high prothrombin time and clotting time to normal within 7 days.

'Environmental temperature and 'rat acrodynia,' P. GYÖRGEY (*Jour. Nutr.*, 16 (1938), No. 1, pp. 69-77).—In a further investigation of the skin manifestations described in a previous report (*E. S. R.*, 79, p. 713), the author found that rats exposed to an environment at a temperature of 40° F. developed the dermatitis symptoms of rat acrodynia earlier than did rats kept on the test diet at room temperature. The condition was prevented or cured by the administration of Peters' eluate.

Rat acrodynia and the essential fatty acids, F. W. QUACKENBUSH, B. R. PLATZ, and H. STEENBOCK. (*Wis. Expt. Sta.*). (*Jour. Nutr.*, 17 (1939), No. 2, pp. 115-126).—The conflicting literature on the relation of certain constituents of the diet to the production and cure of dermatitis in rats is reviewed briefly, and results obtained in a series of tests with various diets and fat supplements are reported. Initial storage of the factors essential for the development of dermatitis was largely prevented by the use, during the nursing period, of a diet in which potato meal replaced the grains of the customary stock diet. The basal diet found most satisfactory for the tests consisted of purified casein 18, cerelose 78, and Wesson salt mixture 4 parts, supplemented with β -carotene 10 μ g., synthetic vitamin B₁ 10, riboflavin 20, and calciferol 5 μ g. daily. After 4 or 5 weeks on this diet the rats developed an acute form of dermatitis with involvement chiefly of the lips, eyes, and forepaws. The animals became inactive, lost from 5 to 10 gm. in weight, and died within a few days. In animals receiving supplements of low potency, a chronic form of dermatitis developed with very extensive lesions involving the entire periphery. Ringlets of scales appeared on the tail, and the body was covered by minute adherent scales.

In order to evaluate quantitatively the potency of various curative agents a chart was prepared giving the appearance of lips, eyes, forepaws, hind paws, ears, and tail in 4 stages of dermatitis. The animals were given the supplements to be tested as soon as the lips and paws had reached stage 2 to 3, and a cure was assumed to have been effected if at the end of 21 days the lips, eyes, and ears were normal and the paws and tail free from all symptoms except a dry scaliness. A minimum curative dose was defined as one which when given daily produced cures in more than 50 percent of the animals with none failing to respond to twice the amount of the same supplements. Cures were produced with $1\frac{1}{2}$ drop of wheat-germ oil, corn oil, or Wesson oil: 1 drop

of commercial or purified peanut oil; 2 drops of commercial or purified linseed oil or lard; 5 drops of olive oil; 10 drops of coconut oil; and 25 drops of butterfat. No cure was effected with hydrogenated coconut oil, cod-liver oil, or halibut-liver oil. When wheat-germ oil was fractionated and tested, the entire activity was contained in the ethyl ester prepared from the soap fraction. Fractionation of the unsaturated fatty acids gave the highest potency, with the fraction separating between -50° and -75° C. One-half drop of ethyl linoleate per day cured the dermatitis completely.

Cure of microcytic hypochromic anemia in dogs with crystalline "factor I," P. F. FOUTS, O. M. HELMER, and S. LEPKOVSKY. (Univ. Calif. et al.). (*Soc. Expt. Biol. and Med. Proc.*, 40 (1939), No. 1, pp. 4, 5).—In continuation of a previous study (E. S. R., 80, p. 711), the authors report that the three dogs with microcytic hypochromic anemia were cured by the addition of crystalline factor I (rat antidermatitis factor, vitamin B₆).

The assay of urine in canine blacktongue by the use of *Shigella paradysenteriae* (Sonne), H. F. FRASER, N. H. TOPPING, and W. H. SEBRELL (*Pub. Health Rpts. [U. S.]*, 53 (1938), No. 41, pp. 1836-1842).—Samples of urine were collected from six dogs while (1) on the stock ration 326, (2) on the blacktongue-producing diet 123, (3) at the first appearance of symptoms of blacktongue, and (4) when the dogs were receiving the stock diet and after the blacktongue symptoms had entirely disappeared. The experimental diet was supplemented by 5 mg. of nicotinic acid per kilogram of body weight given intramuscularly to four of the dogs. The nicotinic acid content of the urine samples was determined by studying the growth of *S. paradysenteria* (Sonne N. I. H. 741), which requires the presence of nicotinic acid or related compounds.

After from 31 to 52 days on diet 123, the bacterial growth-promoting property of the urine markedly decreased. In the dogs given nicotinic acid, the bacterial growth-promoting property of the urine increased for 1 hr. following the administration and from 48 to 72 hr. later returned to the level existing when the dogs were receiving the stock diet.

Treatment of pellagra with nicotinamide, A. C. ALPERT, P. GHALIOUNGUL, and G. HANNA (*Lancet [London]*, 1938, II, No. 26, pp. 1460-1463).—The daily administration of 1 gm. of nicotinamide by mouth or 0.5 gm. by injection to 15 patients with pellagra and dermatitis and 2 with pellagrous stomatitis produced great improvement in the acute mucous membrane lesions and acute skin conditions, as well as in the appetite, mental condition, and general physical health of all the patients within from 2 to more than 20 days. Chronic skin lesions in friction places and chronic atrophic changes in the tongue were only slightly improved.

When 9 of the patients were given marmite for from 7 to 25 days before the nicotinamide therapy, there was either no improvement or the condition became aggravated in all but 1 case. While the 1-gm. dose of nicotinamide produced transient headache in 2 patients, the same dose of nicotinic acid caused headache, itching, and warmth of the skin in the 5 patients receiving it. During the treatment with nicotinamide, the patients were under strict dietetic observance and meat and milk were withheld.

The modern treatment of diabetes, J. R. SCOTT (*Bul. N. Y. Acad. Med.*, 2. ser., 14 (1938), No. 8, pp. 480-490, figs. 2).—In this lecture, by the chairman of the New York Diabetes Association, the principles constituting a guide for the modern treatment of diabetes are first enumerated, and the actual management of the diabetic patient is then discussed under the headings education of the patient, diet, insulin, complications, and significances of laboratory findings. The principles of the treatment as far as diet is concerned are to main-

tain the patient at or slightly below the ideal body weight, divide the day's food allowance into three meals and three supplementary feedings, provide 1 gm. of protein per kilogram of body weight per 24 hr. for adults and from 2 to 3 gm. for rapidly growing children, provide carbohydrate somewhere in the middle range of 120-200 gm. per 24 hr., restrict fat to the least possible amount consistent with the maintenance of an ideal body weight, and add vitamin concentrates to make up for the deficiency in fat-soluble vitamins inherent in the low-fat diets.

Iodine and the incidence of goiter, J. F. McCLENDON (*Minneapolis: Univ. Minn. Press; London: Oxford Univ. Press, [1939], pp. VI+[4]+126, figs. 64*).—This exhaustive compilation, intended primarily for the use of research workers and those interested in goiter prophylaxis, deals with the distribution of iodine in soils, water, foods of animal and vegetable origin, and the human body; the geographic distribution of goiter and cretinism throughout the world; and methods for the determination of iodine. Literature references are given as footnotes, numerical data in a series of 79 tables, and miscellaneous illustrative material in numerous diagrams and maps.

Contamination of drinking glasses by streptococci, L. A. DICK. (N. Y. State Expt. Sta.). (*Jour. Bact.*, 37 (1939), No. 2, pp. 224, 225).—In a brief note the author reports that *Streptococcus salivarius* was recovered from the lips of 160 individuals and from the rims of drinking glasses used by the subjects.

TEXTILES AND CLOTHING

Manufacturing and serviceability tests on sheetings made from two selected mill types of cotton, R. E. ROGERS, M. B. HAYS, and J. T. WINGGTON (*U. S. Dept. Agr., Tech. Bul.* 645 (1939), pp. 32, figs. 14).—The cotton used in these tests, which represent an extension of a previously noted cooperative project of the Bureaus of Home Economics and Agricultural Economics (*U. S. R.*, 71, p. 428), was representative of two mill types of American upland cotton ranging from Middling to Strict Middling when made into heavy sheets. The same general plan was followed as in the earlier study, but more sheets in each lot were put into service, a larger sample was taken each test period, and additional laboratory tests were performed. Cotton A, which was grown in the vicinity of Somerton, Ariz., ranged from Middling Light Spotted to Strict Middling Spotted in grade and from $1\frac{1}{16}$ to 1 in. in staple length. Cotton B, which was grown in Arkansas, was classed as Middling to Strict Middling in grade and ranged from $3\frac{1}{32}$ to $1\frac{1}{16}$ in. in staple length. The test cottons and a commercial mixture of 20 percent Cotton A and 80 percent Cotton B were spun, woven into heavyweight muslin sheeting, bleached, and finished under similar mechanical and moisture conditions. The sheets were put into use in a Washington hotel under the same conditions as in the earlier study. The sheets, which were tested in the unbleached state and when finished, were tested at regular intervals in 25 launderings through the two hundred and seventy-fifth laundering period. The length of service beyond this point was also noted.

The first laundering removed the largest percentage of starch. A measurable amount was found after the twenty-fifth but not after the fiftieth laundering. Wear and laundering produced a progressive tendering in all three fabrics, and the length of service did not differ markedly, being 281 periods for the sheets made from Cotton A, 276 from Cotton B, and 278 from the mixed cotton. Wear had more effect on the physical than the chemical properties of the sheeting, as shown by the fact that the physical values for

the sides of the sheets after 250 launderings were similar to those of the center after 200 launderings, while the chemical values of the sides were approximately equal to the centers after 225 launderings. The unbleached sheets made from Cotton A showed more deterioration, both physically and chemically, than the two other unbleached sheets. This was also true, in general, of the bleached sheets. However, the differences in the deterioration of the two types of cottons were considered not great enough to affect serviceability.

The testing of yarns and fabrics, H. P. CURTIS (*London and New York: Isaac Pitman & Sons, 1938, 3. ed., pp. XIII+241, figs. 94*).—An enlarged edition of a book noted earlier (E. S. R., 66, p. 97).

HOME MANAGEMENT AND EQUIPMENT

Family income and expenditures: Pacific Region.—I, Family income, D. MONROE, M. S. WEBER, and H. HOLLINGSWORTH (*U. S. Dept. Agr., Misc. Pub. 339 (1939), pp. IV+380, figs. 19*).—This report is the first of a series covering income and expenditures of small-city and village families as part of the extensive consumer purchases study conducted under the auspices of the Works Progress Administration and noted previously in the annual report of the Bureau of Home Economics (E. S. R., 80, p. 717). The report contains a foreword by L. Stanley; an introductory section describing the purpose of the study, selection of communities throughout the country, sampling procedures, number and scope of the records obtained, and a description of the Pacific small cities and villages studied; two sections dealing with the presentation of the data for small-city families and village families, respectively; and a series of appendixes giving the detailed methodology for the collection and analysis of the data, an appraisal of the families from which income data were obtained, and a glossary of terms used in all phases of the study. For both small cities and villages the material presented is classified under the characteristics of the families and their households, family income, family occupation and income, earnings of husband and wife in relation to age and occupation, type and income, living quarters, home tenure, and rentals.

Some practical aspects of lighting kitchen work areas, J. T. BAILEY (*Illum. Engin. Soc. Trans., 33 (1938), No. 8, pp. 725-733, figs. 5*).—Several methods of lighting kitchen work areas, particularly the sink and under cabinets, are described, with diagrams of the mounting positions and constructional features of local lighting equipment, the distribution characteristics of various types of reflectors, and a typical modern kitchen showing the recommendations for general and local lighting. Surface materials and colors are discussed from the standpoint of reflection and glare.

MISCELLANEOUS

Federal legislation, rulings, and regulations affecting the State agricultural experiment stations (*U. S. Dept. Agr., Misc. Pub. 348 (1939), pp. 38*).—A revision of Miscellaneous Publication 202 (E. S. R., 72, p. 141).

Annual Report [of the New Haven Station] for the year ending October 31, 1938, W. L. SLATE (*Connecticut [New Haven] Sta. Bul. 421 (1939), pp. 66*).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

Fifty-first Annual Report of [Kentucky Station], 1938, I, II, T. P. COOPER ET AL. (*Kentucky Sta. Rpt. 1938, pts. 1, pp. 63; 2, pp. [3]+408+11, figs. 67*).—Part 1 includes the report of the director, the experimental work not

previously noted being for the most part abstracted elsewhere in this issue. Part 2 contains reprints of Bulletins 378-388 and Circular 49, previously noted.

Annual report of the Massachusetts Agricultural Experiment Station, 1938, F. J. SIEVERS ET AL. (*Massachusetts Sta. Bul.* 355 (1939), pp. 104, pls. 8).—The experimental work not previously referred to is for the most part noted elsewhere in this issue. An abstract is also included on A Study of Rate of Decomposition of Haddock Muscle at Various Temperatures as Indicated by Ammonia Content, by G. C. Crooks and W. S. Ritchie (pp. 102, 103).

Forty-fifth Annual Report [of Minnesota Station], W. C. COFFEY (*Minnesota Sta. Rpt.* 1938, pp. 93).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

Annual Report of [Puerto Rico College Station, 1938], J. A. B. NOLLA ET AL. (*Puerto Rico Col. Sta. Rpt.* 1938, pp. [4]+114, pl. 1, figs. 14).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

What's new in farm science: Annual report of the director, [Wisconsin Station, 1938], II, compiled by N. CLARK and N. HOVELAND (*Wisconsin Sta. Bul.* 448 (1939), pp. 96, figs. 27).—This supplements and completes the report previously noted (*El. S. R.*, 81, p. 158), dealing with the subjects of garden, orchard, and cash crops; plant diseases; insect pests; soils; field crops; livestock feeding; and poultry. The experimental work not previously reported is for the most part noted elsewhere in this issue.

Forty-eighth Annual Report of [Wyoming Station, 1938], J. A. HILL (*Wyoming Sta. Rpt.* 1938, pp. 48).—The experimental work not previously referred to is for the most part noted elsewhere in this issue. Meteorological data are also included.

Bimonthly Bulletin, [May 1939] (North Dakota Sta. Bimo. Bul., 1 (1939), No. 5, pp. 51, figs. 9).—In addition to several articles noted elsewhere in this issue, there are included Plants of the Mustard Family in North Dakota, by O. A. Stevens (pp. 7-10); Relationship of Farm Population Movement and Drought (pp. 23-25), by D. G. Hay; and the customary abstracts.

NOTES

Arizona University and Station.—A foreman's cottage was recently completed as a part of the developmental program on a new farm, located on the Yuma Mesa, which has been set aside for the use of the university by the Federal Government.

Dr. P. S. Burgess has returned as dean of the College of Agriculture and director of the station after a year in a similar capacity at the Rhode Island College and Station. Dr. R. S. Hawkins, who has served as acting dean and acting director, has been appointed vice dean and vice director in addition to reassuming his position as head of the agronomy department. C. W. Van Horn returned September 1 as assistant horticulturist after a year's graduate study at the University of Maryland. Dr. H. G. Johnston, associate professor of entomology in the Texas College, has been appointed entomologist, beginning July 15 and dividing his time equally between the station and the extension service. Fred Gremmel, assistant professor of animal husbandry and assistant animal husbandman, resigned August 8 to become associated with the U. S. D. A. Soil Conservation Service in Texas.

Connecticut State Station.—The General Assembly of Connecticut increased the station's maintenance appropriation for the biennium beginning July 1, 1939, by \$35,000 per year. This is a restoration of reductions voluntarily made by the station in 1933. The Assembly also appropriated \$15,000 for new greenhouses.

A new laboratory and service building, including an assembly room and garage, is being erected on the station grounds. A new laboratory is also under construction at the Tobacco Substation.

Dr. O. E. Street, plant physiologist at the Tobacco Substation, has resigned to become agronomist in charge of the Federal tobacco station in Lancaster County, Pa., beginning August 15. Dr. Raimon Beard has been appointed assistant entomologist.

Florida University.—Plans are being made for an Inter-American Educational and Cultural Conference to be held at the university in April 1940 under a special grant from the Carnegie Endowment for International Peace. Sections will be organized in history and geography, literature, music and drama, art and architecture, economic and social problems, Government and public administration, and education. Participation by representatives of Latin American countries will be emphasized.

Illinois University and Station.—Dr. William E. Carroll, chief of swine husbandry, has been appointed head of the department of animal husbandry.

Kansas College and Station.—The first of several industrial fellowships for research in chemurgy (the industrial utilization of farm products) is announced. This fellowship is to undertake a study of the economic feasibility in Kansas of the manufacture of starch from Irish potatoes, sweetpotatoes, and other farm products. It is pointed out that although the 1928-32 State average production of potatoes was 2½ million bushels with a market value of \$1,500,000,

production has declined 50 percent because of poor market outlets and other factors.

Drs. O. A. Shaw, instructor and assistant in dairy husbandry in the Idaho University and Station, and H. E. Bechtel have accepted positions in the department of dairy husbandry. Dr. Katherine Roy has been appointed head of the department of child welfare and eugenics.

Kentucky Station.—R. K. Calfee has resigned as assistant chemist.

Maine University.—Gordon M. Cairns has been appointed head of the department of animal industry vice L. S. Corbett, who will give his entire attention to the deanship of men.

Mississippi College and Station.—Henry H. Leveck, associate professor of animal husbandry and associate animal husbandman, has been appointed head of the department vice Dr. E. W. Sheets, resigned. A. E. Cullison, assistant in animal husbandry in the Illinois University and Station, has been added to the animal husbandry department.

New Jersey Stations.—Construction is nearing completion on a turkey research substation authorized by the 1938 legislature. This station is located at Millville, Cumberland County, on an 18-acre tract which also includes the pigeon breeding contest. The county is building a five-room headquarters building 24 by 30 ft., two stories high, with an office, incubator room, killing room, feed room, and a room for meetings. The plant will include six colony brooder houses 10 by 12 ft. with 20-ft. wire sun porches, two 10 by 12 breeder units, and six summer shelters. Dedication will take place October 12 in conjunction with the annual New Jersey Turkey Field Day and work will start November 1, with an assistant poultry husbandman in charge. About 300 turkeys will be reared the first year. The program embraces feeding studies and breeding of a broad-breasted small turkey for family consumption. Possibilities of smoking and quick freezing will also be explored.

About 35 executives of press and radio from New York, New Jersey, and Philadelphia were guests of the station August 14, witnessing demonstrations of research in several departments.

Recent appointments include Charles A. Thompson as State leader of county agents vice Edwin A. Gaunt, resigned, and Van Wie Ingham, formerly executive secretary of the State soil conservation committee, as assistant to the dean of the college of agriculture and director of the stations.

New York State Station.—Dr. G. L. McNew of the Rockefeller Institute has been appointed chief of research (plant pathology). Dolores Weimer, assistant in seed investigations, has resigned to engage in commercial work.

Ohio Station.—Recent appointments include Dr. Arthur R. Mangus as associate in rural economics and E. Wise Burroughs and Irvin W. Wander as assistants in animal industry and horticulture, respectively.

Oklahoma College and Station.—Harry W. Cave, professor of dairy husbandry in the Kansas College and Station, has been appointed in charge of the dairy department after September 1. Dr. Frank B. Cross, acting head of the department of horticulture, has been given permanent charge of that department.

Rhode Island College and Station.—Dr. Cooper Curtice, associated with the zoological and animal husbandry work from 1900 to 1907 and who retired as veterinarian in the U. S. D. A. Bureau of Animal Industry in 1930, died August 8 aged 83 yr. A native of Connecticut, Dr. Curtice was graduated from Cornell University in 1881 and received the D. V. S. degree from Columbian Veterinary College in 1883 and the M. D. degree from the National Medical College in 1888. He served with the U. S. Department of Agriculture from

1886-92, 1895-97, and 1907-30 and was also veterinarian with the New York State Board of Health, 1893-94 and 1897-98, and with the North Carolina College and State Board of Agriculture from 1899 to 1900. He worked on a considerable variety of problems, including intestinal parasites of sheep, black-head and other diseases of turkeys, the incubation and rearing of poultry, and fowl and goose septicemia, but was probably most widely known for his extensive contributions to the eradication of cattle ticks and tick fever.

Texas College and Station.—Dr. H. H. Harrington, president from 1905 to 1907, director of the station from 1906 to 1911, and associated with the chemical work of the institution from 1888 to 1906, died August 16, aged 79 years. He was a graduate of the Mississippi College and served there as assistant chemist from 1882 to 1888.

Dr. D. W. Thorne, associate professor of agronomy, has resigned to become associate professor of soils and associate agronomist in the Utah College and Station.

Vermont Station.—The main dairy barn on the University Farm burned at noon on August 22, the cause being spontaneous combustion in a large mass of chopped hay. Director Hills writes that "no animals were lost. Indeed, animals were gained in that a calf was born during the fire in the basement of the barn. The fact that the buildings were covered with asbestos cement shingles, together with the excellent work of the city fire department, enabled the saving of all the rest of the buildings."

Office of Experiment Stations.—John I. Schulte, associated with the Office since 1897 in various capacities, has retired as of November 1, 1930. A native of Iowa and a graduate of the Iowa College in 1895, he remained there as assistant in horticulture for the ensuing 2 years. His early service in the U. S. Department of Agriculture was as specialist in field crops on *Experiment Station Record*. He continued to have charge of this work during most of the next 20 years and also did some abstracting in animal husbandry, dairying, and in other lines. More recently he has been associated mainly with the administrative work of the Office in its relations with the State experiment stations, notably in the assembling of records and statistics, the interpretation of laws and rulings, and many miscellaneous matters. One special activity was his assembling and installation of Department and experiment station exhibits at several world's expositions in this country and abroad, and another his service as interpreter and guide to a number of distinguished delegations of visitors from foreign institutions seeking a knowledge of American agriculture. In 1900 he was a member of the international jury of awards at the Paris Exposition and received in connection with this service the designation from the French Government of Chevalier du Mérite Agricole. His broad knowledge of agricultural science and institutions, his proficiency in foreign languages, his versatility and adaptability, and his sound judgment and dependability made him of unique value in the Office organization and his retirement a real loss in many directions.

Dr. Georgian Adams, associate home economics specialist in the Bureau of Home Economics, has been appointed associate home economist vice Mabel Dickson Dill, resigned, and has entered upon her duties.

New Journals.—*Dairy Science Abstracts* is being published by the Imperial Bureau of Dairy Science at Shinfield, Reading, England. The initial number contains about 500 abstracts classified under the headings of husbandry, technology, control and standards, economics, physiology, bacteriology and mycology, chemistry and physics, and miscellaneous.

A merger of the Central Society of Veterinary Medicine and the Japanese Society of Veterinary Science under the latter title has resulted in the discon-

tinuance of their former journals and the establishment of *The Japanese Journal of Veterinary Science*. Among the articles in the initial number is one in English by J. Nakamura entitled Complement-Fixation Reaction in Rinderpest—V, Distribution of Antigen in the Body of the Infected Calf.

An Industrial and News Edition of the *Journal of the Indian Chemical Society* is being published under the joint auspices of the Indian Chemical Society and the Institution of Chemists (India) at 92 Upper Circular Road, Calcutta. The initial number contains among other material an address entitled Mineral Elements in Nutrition, by U. P. Basu.

Archiv für die gesamte Virusforschung is being published from time to time by Julius Springer, Wien (Vienna), under the supervision of a board from various countries, including R. E. Shope and W. M. Stanley of Princeton. The initial number contains 12 original articles in English, French, or German on plant and animal virus problems.

The Journal of Endocrinology is being published at the Courtauld Institute of Biochemistry, Middlesex Hospital, London, W. 1. The initial number contains 11 original articles.

Miscellaneous.—Dr. William W. Skinner has been appointed associate chief of the U. S. D. A. Bureau of Agricultural Chemistry and Engineering. In association with the chief of the bureau he will assist in the supervision and direction of all scientific, technical engineering, and administrative work, including the four regional research laboratories.

Dr. Walter C. Lowdermilk, chief of the division of research of the U. S. D. A. Soil Conservation Service, has been investigating soil conservation in Palestine on the request of that government, spending several weeks in observations which have extended into Negeb and to the Aqaba area of Transjordan.

Dr. Franklin S. Harris, president of Brigham Young University and previously director of the Utah Station, has been given leave of absence to reorganize the department of agriculture of Iran and to plan for the rehabilitation of the agriculture of that country.

EXPERIMENT STATION RECORD

VOL 81

NOVEMBER 1939

No. 5

THE THIRD INTERNATIONAL CONGRESS FOR MICROBIOLOGY

By FREDERICK V. RAND

Senior Pathologist, Office of Experiment Stations

The International Congress for Microbiology, the third session of which was held in New York City from September 2 to 9, 1939, is not as youthful an institution as might be inferred from a total of only three meetings. Actually, the organization is an outgrowth of an older institution, The International Congress of Hygiene and Demography, which was discontinued after its fifteenth meeting in Washington, D. C., in 1912, as a result of the World War and its aftermath. According to the constitution adopted for the present "International Association of Microbiologists" at its first meeting (Paris, 1930), its object is "to promote scientific thought by creating a closer relationship between the workers in the different countries, and especially to spread the idea that all its members should be united in a common ideal of peace and constant friendship." At no period since its original inception have these sentiments been more timely.

Many of the 400 or more foreign scientists who had planned to attend the Congress remained at home because of the imminence of war. Nevertheless, the total registration was 1,591, and in spite of the tragic political situations in Europe and elsewhere 150 members were registered and present from over 30 lands outside the United States. The British Isles led with 52, followed by Canada with 20, Norway and Sweden with 10, Belgium with 7, France with 5, Cuba, Denmark, Japan, and Switzerland with 4 each, and Hawaii, Hungary, Germany, and Palestine with 3 each. South American countries, including Brazil, Argentina, and Uruguay, were represented by 12, and there were 1 or 2 delegates each from such far-flung quarters of the earth as Africa, Australia, Ceylon, China, Finland, Mexico, The Netherlands, Poland, Rumania, and Turkey.

Many representatives of the State experiment stations and of the United States Department of Agriculture contributed important papers to the program. The large volume of proceedings will contain much that represents fundamental advances in the study of micro-

organisms which cannot fail to prove of basic value in connection with agricultural progress.

The welcoming address to members of the Congress and their friends at the opening meeting and reception was given by Dr. Thomas M. Rivers, director of the Rockefeller Institute and president of the Congress. He referred to the modern microbiologists as equaling and in some cases surpassing the achievements in the "Golden Age of microbiology." "True," he said, "we stand on the shoulders of those who preceded us and we should respect their accomplishments . . ., but if the abstracts of 600 communications on this program can be considered as indicative of the character of work now in progress it is obvious that these workers are true sons and daughters of the nineteenth century microbiologists." Among the high lights of recent microbiological research which he touched upon were the unprecedented advances in chemotherapy, bacteriotherapy, and immunotherapy, the striking regularity with which new viruses are being discovered, the isolation of virus proteins in both the plant and animal fields, with the consequent revolutionary changes in our ideas of nature, the fashioning of a bridle to yellow fever, and the delving into the secrets of the physiology and nutrition of the bacteria themselves, which "without doubt will aid investigators interested in the higher forms of life."

Mayor LaGuardia of New York and Dr. John L. Rice, Commissioner of Health, proffered the welcome of the city and the Health Department to the Congress. Sir John C. G. Ledingham, director of the Lister Institute and president of the Second Congress (London, 1936), expressed the appreciation of the foreign members to the Executive Committee which had so efficiently planned this Congress. He asserted that in the field of microbiology "you in the United States have been greatly blessed by the bountiful support given by private benefactors, and we foreign delegates from many countries have ample reason to be grateful. . . . Your Federal Government also has not been behindhand in voting public funds for numerous scientific objects in which microbiology has a part to play. . . . It is abundantly clear that in its support of those spheres of science which this Congress takes under its purview, the United States presents a noble example to the world." Dr. Lewis R. Jones, emeritus professor, University of Wisconsin, representing the field of plant science, stressed the significance and unity of the various lines of microbiological work, the timeliness of research in this field, and the deeper significance in the progress as a whole than for that of any of its parts. One hundred years ago biology was started on a microbiological basis. The stabilizing influence of the cell theory has guided the physiologist and cytologist and furthered evolutionary

thought. Referring to fungus, bacterial, and virus diseases in plants, Dr. Jones stated further that there has been a steadily increasing correlation of plant pathology and biological research as a whole with animal pathology. Work with plant virus problems already offers much promise concerning the intimate relations of virus and host tissues, but even more significant are the definitions of basic questions as to the character or nature of the virus itself. "What in the realm of microbiology," he added, "is more challenging than this!"

At the official banquet, high tribute was paid by Dr. E. G. D. Murray, professor of bacteriology and immunity at McGill University, to Dr. Theobald Smith, "Father of American Bacteriology," in whose memory the Congress had struck off a bronze medal for its members. Dr. Karl F. Meyer, director of the Hooper Foundation of the University of California, gave a toast to the foreign members of the Congress and their guests, and in concluding said, "I give you the sacred bonds of science which go beyond all bonds of nationality or creed." In reply, Prof. S. Orla-Jensen of the Royal Technical College, Copenhagen, transmitted the cordial invitation of the Danish Government for the Fourth Congress to meet in Copenhagen in 1942, and expressed his personal satisfaction that it had already been accepted. Dr. Joseph W. Bigger of Dublin, Prof. Estenio Hormaeche of Montevideo, Dr. N. H. Swellengrebel of Amsterdam, Prof. André Gratia of Liege, Prof. Ch. Oberling of Strasbourg, and Sir John Ledingham also spoke.

Besides the three general scientific meetings open to the public, the official sessions were scheduled under nine subject sections, which in some cases were subdivided further. For example, in agricultural and industrial microbiology the programs were grouped under soil microbiology, foodstuffs and spoilage, dairy bacteriology, bacteriology of water and sewage, and fermentations. The nine main sections dealt, respectively, with variation and taxonomy, microbiological chemistry and physiology, viruses and viral diseases, rickettsiae and rickettsial diseases, protozoology and parasitology, fungi and fungus diseases, medical and veterinary bacteriology, agricultural and industrial microbiology, and immunology. Furthermore, and preceding the Congress proper, three symposia dealing with different phases of soil microbiology formed the subjects of meetings of the Third Commission of the International Society of Soil Science on August 30-31 at New Brunswick, N. J.

From a program in which some 600 papers were originally scheduled to appear it would be difficult if not impossible to single out one or even a few as exhibiting the outstanding contributions of the Congress. Particularly notable, however, were the advances shown in

the study of viruses. Furthermore, the value of the cinema both for research and for demonstration and educational purposes was well exemplified by motion pictures depicting the life history of bacteria as shown by Dr. Morton C. Kahn of the Cornell University Medical School.

One of the most encouraging general impressions from these sessions was the appearance on many of the same programs of investigators working in both the plant and animal fields, coupled with the very evident mutual respect and with recognition of the reciprocal scientific values of methods and findings in the two fields as brought out both in the papers given and in the discussions which followed. Thus in a single session dealing with variation and taxonomy in special groups of bacteria there were papers on such diverse matters as the relationships of phytopathogenic bacteria, and of the cholera vibrio; filtrable forms of a bacterial parasite of fish; the taxonomy of lactic acid bacteria, streptococci, the proteus group, and mesophilic bacteria; the classification of gram-negative, nonsporiferous anaerobes; and degeneration and variation of gonococci. Similarly, and side by side on various other programs, there were papers on the nomenclature and classification of phytopathogenic viruses, and on the properties of the virus of vaccinia; comparative studies on ultracentrifugation and serological reactions of bacteriophages, plant viruses and insect viruses, and the use of the centrifuge in the study of the yellow fever virus; the control of the bulb or stem nematode, and the occurrence of *Trichinae* in swine; the nature of the growth-stimulating factors for *Rhizobium trifolii*, the synthesis of tryptophane by typhoid bacilli, and growth factors for trichomonads; the fruiting phases of anthracnose fungi in plants, and actinomycosis among cattle and swine; and the control of loose smut of barley, mycorrhizal responses to experimental soil variations, and the biological treatment of dermatomycosis. One of the most interesting sessions was made up of a symposium on host-parasite relationships in which three men from the plant side and three from the animal side spoke, respectively, on etiology and pathogenesis, tissue reactions, and natural resistance, including immunity.

Further evidence auguring well for the future progress of science was also forcefully brought out not alone in the increasing intensification of subject specialization and in the continuous advances in refinement of methods and techniques, but in such developments as these viewed in connection with a growing sense of the essential oneness of all biological research which is drawing together many superficially unrelated interests in united international efforts toward common ends. It is to be hoped that this example will not be entirely lost on the world of today.

RECENT WORK IN AGRICULTURAL SCIENCE

AGRICULTURAL AND BIOLOGICAL CHEMISTRY

[Chemical investigations of the Indiana Station]. (Partly coop. U. S. D. A.). (*Indiana Sta. Rpt.* 1938, pp. 8-10, 12, 13, 74, 75, fig. 1).—These have included work on chemical studies on pure lines of corn, by D. M. Doty; analyses of commercial soybean oils and drying rates when mixed with 10 percent tung oil, by H. R. Kraybill, A. W. Kleinsmith, and M. H. Thornton, nonfat constituents of soybean oil, by Thornton and Kraybill; carbohydrates of the soybean, by E. D. Walter and Kraybill; photoelectric photometer, by F. P. Zscheile, C. L. Shrewsbury, and Kraybill; carotenoid pigments, by Zscheile and J. W. White; and mint oil, by F. C. Gaylord and K. I. Fawcett.

Oxidation-reduction potentials and pH values in soils, V. M. CONWAY (*Chron. Bot.*, 5 (1939), No. 2-3, pp. 167, 168).—A review with citations.

A preliminary report on a simple and rapid method for determining the moisture content of dates, G. L. RYGA. (U. S. D. A.). (*Date Growers' Inst. Rpt.*, 15 (1938), pp. 4, 5).—The use of a refractometer for quickly determining the moisture content of date fruits is discussed. In no case did the refractometer readings differ from those obtained by the toluene method by more than about 1 percent.

The semi-quantitative estimation of mineral oil in the shells of processed eggs, S. R. HOOVER. (U. S. D. A.). (*U. S. Egg and Poultry Mag.*, 45 (1939), No. 3, pp. 162, 163, 188).—The simple method described for the rapid estimation of the oil contents of the shells of processed eggs essentially consists in measuring the turbidity produced when the shell is boiled with alcoholic sodium hydroxide and then diluted with water. Application of this method revealed a wide variation in the oil content of individual processed eggs, suggesting that this condition may account for some inconsistent results of processing encountered in commercial practice.

Colorimetric methods for the quantitative estimation of indole-3-acetic acid, J. W. MITCHELL and B. C. BRUNSTETTER. (U. S. D. A.). (*Bot. Gaz.*, 100 (1939), No. 4, pp. 802-816, figs. 3).—The methods for measuring indoleacetic acid in water solution included its reaction with (1) KNO_2 and HNO_2 , (2) FeCl_3 and H_2SO_4 , and (3) FeCl_3 and HCl . The nitrite and $\text{FeCl}_3\text{-H}_2\text{SO}_4$ tests were studied in detail to determine the effect of the different factors involved on the intensity and stability of the color produced. The nitrite test proved applicable for determining indoleacetic acid in aqueous solutions at concentrations of 0.01-0.15 mg. per cubic centimeter, while the $\text{FeCl}_3\text{-H}_2\text{SO}_4$ test proved suitable for estimating total amounts of 0.02-0.1 mg., under the test conditions. The latter test was sensitive to essentially the same concentration range as the nitrite test, but was less suitable since the color produced was not stable. There are 10 references.

The quantitative determination of vitamin B_1 [trans. title], A. ST. V. MAL-LINCKRODT-HAUPT (*Klin. Wchnschr.*, 18 (1939), No. 13, pp. 467, 468, fig. 1).—A new photometric method for the determination of vitamin B_1 , making use of the thiochrome reaction, with the measurement of the fluorescence in a Pulfrich photometer, is described. By changing the blue fluorescence to green through

the addition of acetic acid to the isobutyl alcohol (2 cc. of acetic acid to 4 cc. of the alcohol) and using a red filter, the test is made sufficiently sensitive to detect as small an amount of the vitamin as 2γ (1 I. U.) per cubic centimeter of the isobutyl alcohol. Beyond a total content of 0.15 mg. or 75 I. U. of the vitamin the test is no longer satisfactory. Parallel tests with solutions containing known amounts of the vitamin and with fuller's earth adsorbates of the same solutions indicated that the loss of the vitamin through adsorption and subsequent elution is very small. The method has been found satisfactory for use with cultures of yeast and bacteria and with a number of samples of urine.

The vitamin C content of human urine and its determination through the 2,4-dinitrophenylhydrazine derivative of dehydroascorbic acid, J. H. ROE and J. M. HALL (*Jour. Biol. Chem.*, 128 (1939), No. 1, pp. 329-337).—The furfural method for determining ascorbic acid previously described (E. S. R., 77, p. 584) has been applied in comparison with indophenol titration to the urines from 50 normal human subjects. The values are tabulated as ascorbic acid content per liter of urine in place of the usual 24-hr. sample, with no indication as to time of day on which the samples were taken. The urine from 14 of the subjects who were apparently on a good diet showed no vitamin C by the furfural method, and the indophenol titration gave values ranging from 0 to 297 percent higher than those by the furfural method.

AGRICULTURAL METEOROLOGY

A meteorological service of the future, W. C. DEVEREAUX. (U. S. D. A.). (*Bul. Amer. Met. Soc.*, 20 (1939), No. 5, pp. 212-221).—During 1938 the late W. R. Gregg addressed letters to many meteorologists requesting an outline of what a meteorological service 50 yr. from now will be like. This paper consists of extracts from the replies, with comments by the author.

Sensitive open-scale instruments for the detection of minor disturbances of the atmosphere, S. P. FRÆGUSSEN (*Bul. Amer. Met. Soc.*, 20 (1939), No. 4, pp. 135-141, figs. 3).—The author describes and discusses the operation of barographs, thermographs, hygrographs, anemographs, and nephoscopes in successful use.

Some observed effects of certain atmospheric variations, A. V. LOTT (*Ind. Acad. Sci. Proc.*, 53 (1937), pp. 176-183, figs. 5).—The author concludes from this study that all major weather changes in the United States, and possibly throughout the world, seem to be due to changes in the form and position of the world pressure areas, which in turn appear to be due to variations in the velocity of the general circulation. The longitudinal movement of the air, eastward in temperate latitudes, may not be a permanent feature of a planetary wind system. It may be replaced by a latitudinal movement from some southerly or northerly direction. Temperature does not appear to affect the circulation in just the way generally believed, but the circulation has decided effects on the temperature. A more complete knowledge of the variations in the velocity of the general circulation may be of decided advantage in forecasting future weather trends.

The variations of the solar constant and their relation to weather: Reply to Paranjpe and Brunt, C. G. ABBOT (*Quart. Jour. Roy. Met. Soc. [London]*, 65 (1939), No. 280, pp. 215-236, figs. 2).—"The author cites five recent papers containing many evidences of solar change ignored by critics. Chief among them, and in the author's opinion unanswerable, are evidences that day-to-day solar changes profoundly influence temperatures." These relationships are discussed in detail in reply to published criticisms.¹

¹*Quart. Jour. Roy. Met. Soc. [London]*, 64 (1938), No. 276, pp. 459-476.

The variation of solar ultra-violet radiation during the sunspot cycle, E. V. APPLETON and R. NAISMITH (*Phil. Mag. and Jour. Sci.*, 7. ser., 27 (1939), No. 181, pp. 144-148, fig. 1).—"Measurements of upper-atmospheric ionization by the critical frequency method show that the solar ionizing agent (ultraviolet light) responsible for the formation of regions E and F₁ of the ionosphere varies by 120 to 150 percent during the sunspot cycle. The ionization and electrical conductivities of these regions vary correspondingly by 50 to 60 percent."

Fluctuations of ultraviolet solar radiation [trans. title], G. R. MIROZAIKA (*Ztschr. Astrophys.*, 18 (1939), No. 2, pp. 151-154, fig. 1).—The author concludes that the annual fluctuations of ultraviolet solar radiation are insufficient to explain the observed fluctuations in intensity. The theory is adduced that changes in the atmospheric pressure and humidity are responsible for the differences in the intensity.

Studies of the temperature changes conditioned by radiation in the upper troposphere in anticyclone regions [trans. title], F. KORRUM (*Gerlands Beitr. Geophysik*, 54 (1939), No. 2, pp. 148-167, figs. 15).—The author discusses the problems of temperature in relation to subtropical and polar air masses of the upper troposphere in their advection to other latitudes, explaining these phenomena through an adjustment to the conditions of the new surroundings by radiative processes. For the subtropical air masses this involves an increase and for the polar masses a decrease in cooling by radiation. The assimilation is said to occur in such a manner as to gain significance relative to the heat content of the anticyclone.

An investigation of the lapse rate of temperature in the lowest hundred metres of the atmosphere, N. K. JOHNSON and G. S. P. HRYWOOD ([*Gt. Brit. Met. Off., Geophys. Mem.* 77 (1938), pp. 50, pls. 12, figs. 6).—This monograph describes the instrumental equipment employed, gives a detailed analysis of the records obtained during a 5-yr. period, and shows the steps taken to determine the characteristics and possible sources of error in the more important of the instruments. The results obtained by analysis of the records are set out in detail. Comparison of lapse rates at two stations led to the conclusion that both the topographical and the conductivity effects operate to produce similar results, but the meteorological observations did not permit a decision as to how much of the observed difference was due to each of these causes. The following are also discussed, with formulas and tabulations: Atmospheric turbulence calculated from the temperature curves, effect of wind velocity on the lapse rate and turbulence, short period temperature variations, extreme values of the lapse rate, rate of growth of nocturnal inversions, radiation temperature structure, and radiation fog.

A new temperature chart, J. J. GEORGE and R. D. ELLIOTT (*Bul. Amer. Met. Soc.*, 20 (1939), No. 3, pp. 105-117, figs. 12).—The thermal chart described is said to have been of material assistance in map analysis, third dimension picturization, forecasting winds aloft under adverse conditions, and as an aid in identifying the trajectories of air masses. The shortcomings of the method have to do with the computing of winds aloft and the failure to take account of moisture distribution. The physical principles, detailed formulas, and methods of construction involved are taken up in detail.

The land and sea breeze of Door Peninsula, Wisconsin, E. R. MILLER (U. S. D. A.). (*Bul. Amer. Met. Soc.*, 20 (1939), No. 5, pp. 209-211).—In seeking the explanation of the rainfall, temperature range, and length of growing season in the Upper Peninsula of Michigan and the adjacent part of Wisconsin, the conclusion from the observations recorded here is that the lake breeze penetrates only about a mile inland during the heat of the day when the temperature gradi-

ent is steepest. Hence the phenomena of lake influence described as extending 60 miles inland, on the basis of climatic charts, must be ascribed to the movement and mixing of lake air by cyclonic and possibly by monsoonal winds.

What happens to the rain? B. A. KREN (*Quart. Jour. Roy. Met. Soc. [London]*, 65 (1939), No. 280, pp. 123-137, figs. 4).—An address summarized as follows: "An annual rainfall of 30 in. means that 3,000 tons of water fall on an acre of land. In the course of the year this all disappears, by run-off, evaporation, transpiration through vegetation, and by downward percolation. The relative importance of these factors in British and overseas conditions is discussed. Many of the traditional beliefs among farmers and gardeners were based on a theory of water movement that was attractively simple to understand—but incorrect. It is only in recent years that the true picture of the movement of water in the soil has been built up. In consequence, some of the traditional practices need revision, while others now have a different explanation. The new work has also clarified some of the concepts used in hydrology."

The artificial dissipation of fog. D. BRUNT (*Jour. Sci. Instruments*, 16 (1939), No. 5, pp. 137-140).—The author discusses the formation of and the physical conditions in fog, and outlines two methods of dissipating it, viz, the chemical method which aims at destroying the equilibrium between the fog particles and the medium in which they are suspended, and the method of heating the fog until all the water drops evaporate—the latter deemed the more feasible of the two.

Factors influencing tree destruction during the New England hurricane. S. W. BROMLEY (*Science*, 90 (1939), No. 2323, pp. 15, 16).—In comparing five hurricanes in the Southern States with the September 1938 hurricane in New England, the author cites six factors believed to be paramount in explaining the greater susceptibility of the northern trees to the gale, viz, extremely high wind velocities in local areas, types of trees prevalent, tree ages, man-made conditions, insect and fungus injuries to the trees, and soil conditions. The need for planting of sturdy varieties and proper care of the trees are points that are stressed.

Climatic conditions and suggested cropping systems for northwestern Oklahoma. H. A. DANIEL and H. H. FINNELL (*Oklahoma Sta. Cir.* 83 (1939), pp. 26, figs. 9).—An effort is made to outline a system of farming adapted to the climatic conditions of this area. From a summary of previous studies (45 references), it appears that available moisture rather than plant foods is the limiting factor in crop production here, and practices tending to conserve moisture and to adapt the cropping system to the moisture available are discussed. Rotations in dry-land farming should be aimed at using crops adapted to the available soil moisture in a particular season and maintaining a vegetative cover to prevent wind erosion, the effect of the crop on soil fertility being a secondary consideration. Wheat, for cash income, must be planted as often as conditions promise a successful crop, and rainfall data and the amount of raw crop residues in the soil can apparently be used to give a fairly dependable forecast. The system suggested is based on the substitution for wheat of some crop giving more promise of success in years when wheat does not have a favorable prospect. To make use of the sorghum forage produced in such years, the keeping of some livestock is recommended. Appendixes present the data on rainfall, evaporation, and wheat yields on which the proposed cropping system is based.

Local climate and the growth of trees with special reference to frost. W. R. DAY (*Quart. Jour. Roy. Met. Soc. [London]*, 65 (1939), No. 280, pp. 195-209, pls. 3, figs. 2).—Forest types are said to be determined largely by the general climate, but local conditions exercise considerable influence. The natural forest

in Great Britain is composed of some species relatively hardy to frost and others comparatively easily injured by it. The latter species usually form the final woodland, and their successful growth is made possible by the development of favorable conditions of climate and soil within woodland first formed by hardy species. Examples illustrate the effect of overhead and side shelter on the temperature of the air over the ground, and the influence of topography on frost is also illustrated and discussed. The effects of accessory factors, such as soil fertility, local warm or cold situations, and the general suitability of the exotic species to the climate in which they are introduced, are also discussed in relation to frost injury.

The influence of vegetation on climate in West Africa, with particular reference to the protective aspects of forestry in the Gold Coast, H. W. MOOR (*Univ. Oxford. Imp. Forestry Inst., Inst. Paper 17* (1939), pp. 15).—This is a critical review (65 references).

SOILS—FERTILIZERS

[Soil work of the Hawaii Station] (*Hawaii Sta. Rpt. 1938*, pp. 47-53, fig. 1).—Reports on soil nitrogen studies and the carbide method for determining soil moisture, both by E. T. Fukunaga and L. A. Dean; soil phosphorus studies, by Dean; the calcium:magnesium ratio of some Hawaiian soils and quick soil testing, both by C. Lyman and Dean; temperature as a factor in surface-energy relationships; heat of wetting as related to soil-moisture content; and the rate of temperature change in soils are presented.

[Soil investigations at the Idaho Station]. (Partly coop. U. S. D. A. et al.). (*Idaho Sta. Bul. 229* (1939), pp. 16, 17, 27, 36).—Use of borax to relieve alfalfa yellows, comparison of various phosphates, and work on "slick spot" soils are briefly dealt with.

[Soil investigations of the Indiana Station] (*Indiana Sta. Rpt. 1938*, pp. 8, 20, 29, 30, 89, fig. 1).—This report contains notes on acid and base-forming quality of fertilizers, by L. E. Horat; soil conservation, by I. D. Mayer; rapid soil tests indicating widespread fertility deficiencies, by S. F. Thornton, R. A. Weaver, and O. Cudworth; greenhouse pot tests showing relative efficiencies of different phosphates and the relative availability of magnesium compounds, both by Thornton and M. Drake; evidences of the increasing need for available potash on gray flats, by G. P. Walker; seasonal variations in the available phosphate and potash content of soils as measured by the Neubauer and Purdue rapid soil test methods, by Thornton, A. J. Ohlrogge, and S. Alfred; and comparison of different phosphates at the Moses Fell Annex Farm, Bedford.

[Soil work of the Louisiana Rice Station] (*Louisiana Sta., Rice Sta. Bien. Rpt. 1937-38*, pp. 20-23).—Chemical characteristics of soils in the rice area and cylinder experiments at Baton Rouge are discussed by J. F. Reed and M. B. Sturgis; soil fertility studies in the Lake Charles area, by W. J. Peevy and Sturgis; arsenic toxicity to rice, by Sturgis and E. A. Epps; and sulfonation in soils, by Sturgis and M. Stelly.

[Soil investigations of the Nebraska Station] (*Nebraska Sta. Rpt. [1938]*, pp. 13-19, 52).—The report notes work on methods for the estimation of soil organic matter; commercial fertilizers, manure, and lime; revegetation of abandoned land; studies on the solubility of soil phosphorus; factors affecting permeability of soils to water; relationships between slope, depth of topsoil, and productivity; soil erosion control and soil moisture conservation (coop. U. S. D. A.); and water level investigations.

[Soil Survey Reports, 1933 and 1934 Series] (*U. S. Dept. Agr., Bur. Chem. and Soils [Soil Survey Rpts.], Ser. 1933, Nos. 23, pp. 43, figs. 2, map 1;*

24, pp. 44, pls. 3, figs. 2, map 1; 1934, No. 9, pp. 52, pl. 1, figs. 3, map 1).—Except as indicated below, these surveys were made in cooperation with the respective State experiment stations: 1933, Nos. 23, Alfalfa County, Okla., A. W. Goke et al., and 24, Decatur County, Ga., A. H. Hasty et al. (Univ. Ga.), and 1934, No. 9, Kent and Washington Counties, R. I., R. C. Roberts et al.

The soil characteristics of Connecticut land types, M. F. MORGAN (*Connecticut [New Haven] Sta. Bul. 423 (1939), pp. 64, pls. 35, figs. 16*).—This bulletin supersedes part 1 of Bulletin 320 (U. S. R., 64, p. 206).

Excellent airplane photographs have now provided facilities for more rapid and accurate delineation of soils as components of land types. Federal funds have contributed to the preparation of land type and land use maps of the State in some detail. Continued investigations of the chemical and physical factors of soil fertility of various soil types under prevailing agricultural uses have greatly expanded knowledge of the Connecticut soils. The development of rapid methods of chemical soil testing has provided for a wider application of such information. Forest soil studies have given a more complete picture of the chief features of soil profile development under natural conditions.

Horizon variations of three New Hampshire Podzol profiles, W. H. LYFORD, JR. (N. H. Expt. Sta.). (*Soil Sci. Soc. Amer. Proc.*, 3 (1938), pp. 242-246, figs. 2; also *New Hampshire Sta. Sci. Contrib.* 68 [1939], pp. 242-246, figs. 2).—The author points out that although "variations in thickness of the ash-gray A₁ horizon of Podzols may well be shown by means of photographs . . . the variations in position and thickness of the various B horizons may not be as easily shown." In the author's new technic of profile drawing "a string was stretched across the face of the profile and was made horizontal by means of a spirit level. Strings, weighted at the lower end and conveniently marked at 6-in. intervals, were then suspended from the top of the profile. These were placed 1 ft. distant from each other and were adjusted so that one of the 6-in. marks coincided with the horizontal base line. Thus the profile was blocked off, and the use of the horizontal base line allowed the slope of the profile to be shown. The various horizons could be outlined rapidly and accurately by the use of a similarly blocked sketch paper." Parts of drawings of three profiles are shown, and detailed descriptions of the soils illustrated are given.

A general conclusion indicated by such profile drawings is that the Podzols which have a bleicherde and orterde only exhibit extremely irregular but more or less continuous horizons occurring in a predictable succession, while the Podzols which by reason of parent material or climatic conditions have developed an ortstein exhibit extremely irregular discontinuous B horizons which, although they tend to occur in a typical succession, may occur in some unpredictable sequence.

Effect of soil type, slope, and surface conditions on intake of water, F. L. DULEY and L. L. KELLY. (Coop. U. S. D. A.). (*Nebraska Sta. Res. Bul. 112 (1939), pp. 16, figs. 5*).—The authors sprinkled 0.005-acre plats of various soils from an overhead oscillating sprinkling device with fan-shaped nozzles. A constant water head was maintained by pumping from a large supply tank into a smaller, elevated, constant-level tank. The rate of application was determined by a special water meter, and the run-off was measured in a two-compartment tank calibrated to 0.001 in. of run-off from the plat area. The time required for a given run-off to take place was read on a stop watch. From these data rate curves for both run-off and infiltration were obtained.

The rate of intake of water at the beginning of application was often very high, decreasing rapidly at first, and finally reaching an approximately constant infiltration rate. The total intake of water and also the final infiltration rates

on cultivated bare land showed much less variation among the different soil types than was anticipated. The soils tested varied greatly in the texture of the surface soil and in profile characteristics, but the quantity of water taken in during a given time was strikingly similar for all soils, and the infiltration rates were finally reduced almost to a common level. Even sandy soils closed up until infiltration was very slow.

The total intake and the infiltration rate decreased slightly with increase in slope. However, this change in infiltration rate was found very small and very gradual with changes in slope above about 2 percent.

There seemed to be no consistent or significant difference in the rate of infiltration due to difference in the rate of application of water when the rate of application materially exceeded the rate of intake. With continuous application of water the rate of infiltration gradually decreased to a point where it became nearly, but not absolutely, constant. A plat which received water and was then allowed to stand for a short time showed a sharp decrease in the infiltration rate. However, upon standing for several days or a week and then receiving another application the infiltration rate approached a constant usually higher than that at the end of the previous application period. This rate was again reduced after the plat had again stood in a wet condition.

Soils covered with a crop showed a much higher rate of intake of water than bare soils and maintained this higher infiltration rate throughout extended tests. The denser crops like native sod and alfalfa showed the highest and the longest maintained infiltration rates. Sod land with grass clipped close and surface debris removed showed a rate only a little above that of bare cultivated soil. Soil covered with crop residue such as straw or other organic material gave an infiltration rate similar to or possibly higher than that obtained when the soil was protected by a dense growing crop. The total intake of water when the soil was thus protected was very great on all the soil types tested, and the high rate of intake was maintained over an extended period. In fact, it was sufficient to take care of an amount of water greater than that likely to be received during any rainfall period in Nebraska. Claypan soils (Pawnee clay loam and Butler silty clay loam) absorbed large quantities of water within a short period of time whenever the surface was protected by means of a straw mulch.

"There may be far greater variation between the rates obtained under different surface conditions on a single soil than would be shown by different soils having the same surface conditions. This may make it necessary to think of infiltration rates characteristic of surface conditions rather than of different soils. . . .

"The breaking down of soil structure, by the compacting effect of the rain and the assorting and rearranging of the soil particles by running water forming a compacted layer at the immediate surface, appears to be the principal reason for the low infiltration rates on cultivated land. The formation of this semipervious layer, often only a few millimeters thick, was largely prevented by a covering of straw or by a growing crop."

Boron as a fertilizer for western Oregon soils, W. L. POWERS. (Oreg. Expt. Sta.). (*Science*, 90 (1939), No. 2324, pp. 36, 37).—This is a brief summary on the value of minor elements in Oregon soil fertility and plant nutrition, including experiments by the author showing that alfalfa yellow top can be controlled by use of 30 lb. of boric acid per acre; that the use of boron to correct malnutrition in plants has doubled their boron content, slightly affected the protein content, and raised the chlorophyll content 50 percent; that break-down of table beets has been controlled in greenhouse and field; and that symptoms of boron deficiency in celery, asters, broccoli, and cabbage have yielded in a promising way to soil applications of boron. The indicated effects of boron are summarized, and recommendations as to forms of boron and methods of application are given.

AGRICULTURAL BOTANY

[Abstracts of papers presented at the Washington meeting of the National Academy of Sciences, April 1939] (*Science*, 89 (1939), No. 2314, pp. 400, 401, 402).—Abstracts of the following papers of interest to botany are included: Changes of Viscosity and Cell Activity, by W. H. Lewis; The Time Factor in X-Ray Irradiation [*Tradescantia*], by K. Sax; Rhythmical Impulses in the Heart and in a Plant Cell (*Nitella*), by W. J. V. Osterhout and S. E. Hill; Induction of periclinal chimeras in *Datura stramonium* by colchicine treatment, by A. F. Blakeslee, A. D. Bergner, S. Satina, and E. W. Sinnott; The Chemical Induction of Genetic Changes in Fungi, by C. Thom and R. A. Steinberg; and Cellular Relationships During Growth and Differentiation in Plant Growing-Points, by E. W. Sinnott.

[Botanical reviews] (In *Annual Review of Biochemistry*, VIII, edited by J. M. LUCK and J. H. C. SMITH. *Stanford University, Calif.: Stanford Univ. Press*, 1939, vol. 8, pp. 483-540, 611-626).—The following critical reviews included, each with copious bibliographies, are of special interest to botany: Chemical Aspects of Photosynthesis, by H. Gaffron (pp. 483-502); Mineral Nutrition of Plants, by J. W. Shive and W. R. Robbins (pp. 503-520) (Rutgers Univ.); Growth Hormones in the Higher Plants, by F. W. Went (pp. 521-540); and The Biochemistry of Yeast, by E. I. Fulmer (pp. 611-626) (Iowa State Col.).

Amendments proposed to the international rules of botanical nomenclature (1935), C. X. FURTADO (*Gard. Bul. Straits Settlements*, 11 (1939), No. 1, pp. 30).—See also a previous note (E. S. R., 75, p. 753).

The principal orientations of present day biocoenology or plant sociology [trans. title], H. GAMS (*Chron. Bot.*, 5 (1939), No. 2-3, pp. 133-140).—Modern trends in plant ecology are critically reviewed, with copious references to the work of many investigators of this field.

International cooperation among herbaria and taxonomists (*Chron. Bot.*, 5 (1939), No. 2-3, pp. 140-150).—It is concluded from this discussion that international cooperation in plant science is best promoted by international societies of specialists looking after the scientific, professional, and social interests of their members. Therefore, it is suggested that perhaps the time is ripe for establishing an international society of plant taxonomists. As examples of the sort of efforts needed, the current steps in establishing a catalog of the content of the herbaria of the world and in working out a list of standard abbreviations for herbarium use are discussed. The report of J. Lanjouw, On the Standardization of Herbarium Abbreviations, is appended, with a revised list of abbreviations presented for approval.

An automatic plant irrigator and recorder, C. N. JOHNSON and O. A. ATKINS. (Univ. Calif.). (*Plant Physiol.*, 14 (1939), No. 2, pp. 391-393, fig. 1).—The apparatus described and illustrated is said to supply automatically the soil mass within the pot with sufficient water to bring all parts of the contained soil to field capacity, and in addition a counter operated by a mechanism records the number of irrigations applied. Details of construction and operation are given.

Suggestions for the use of Warburg respirometers in plant physiological investigations, J. W. BROWN (*Plant Physiol.*, 14 (1939), No. 2, pp. 309-320, figs. 2).—Studying the O₂ consumption and CO₂ production of acorns, it was found that the accuracy of this method could be increased by certain modifications: A correction should be made for the absorption of O₂ during the interval between the final O₂ and CO₂ readings. Theoretically, a correction should be considered for the solubility of these gases in the reagents before and after mixing, but since reliable solubility values are frequently unavailable for these reagents

more accurate results may be had by omitting a correction for solubility. Differences in respirometer volume prevent direct application of a control correction for CO_2 in the reagents. A sample set of recordings and calculations is presented.

Taxonomy and floristics of the Americas, H. N. MOLDENKE (*Chron. Bot.*, 5 (1939), No. 2-3, pp. 172-176).—A review.

Advances in the systematics of flowering plants [trans. title.] H. SLEUMEER (*Chron. Bot.*, 5 (1939), No. 2-3, pp. 169, 170).—A review of recent contributions.

Taraxacum laevigatum* f. *scapifolium, a new form of dandelion, F. C. GATES and S. F. PRINCE. (Kans. State Col.). (*Kans. Acad. Sci. Trans.*, 41 (1938), pp. 119, 120, figs. 7).—"Since this form suddenly appeared in the general population [southwestern Missouri], has bred true in all the experimental plantings conducted, and has assumed dominance in the dandelion population, it would seem reasonable to give it a name."

The alien plant population of California, W. W. ROBBINS. (Univ. Calif.). (*Calif. Dept. Agr. Bul.*, 28 (1939), No. 2, pp. 163-165).—This is a brief summary of known data on introduced plants growing without cultivation in California, of which there are said to be about 500 species. Of these, some 125 species have become established as weeds of great agricultural significance, while a number of others may be troublesome locally. About 75 percent of the total number of alien plants are introductions from Europe and Asia, while fully 15 percent of these are from the Mediterranean region. Apparently the introduction of alien plants has been largely determined by the movements of peoples. At the time of writing there was said to be a number of plant immigrants, recognized in other parts of the world as bad weeds and manifesting the same tendencies under California conditions, which thus far have a relatively limited distribution in the State. The need for control and eradication is stressed.

The central bureau for fungus cultures, Baarn (Netherlands): List of cultures, 1939, J. WESTERDIJK (*Centraalbureau voor Schimmelcultures, Baarn (Holland): List of cultures, 1939. Amsterdam: K. Akad. Wetensch.*, 1939, pp. 132, fig. 1).—This is the list of fungus species for which cultures are now available (E. S. R., 79, p. 608).

Proceedings of local branches of the Society of American Bacteriologists (*Jour. Bact.*, 38 (1939), No. 1, pp. 110, 111, 112, 115, 116).—Abstracts of the following papers of interest to botany are included: Effect of Biotin Concentrates on Growth of *Rhizobium* and Related Species, by P. M. West and P. W. Wilson (Univ. Wis.); Note on the Preparation of Active Cell-Free Juice From Bacteria, by W. P. Wiggert, M. Silverman, M. F. Utter, and C. H. Werkman (Iowa State Col.); Preparation of Bacteriological Peptones, by E. Leifson and B. Diamond; Evidence for the Aerobic Decomposition of Lignin by Lake Bacteria, by J. Stadler and C. E. ZoBell, and The Effect of Oxygen Tension on Oxygen Consumption by Bacteria in Lake Water, by C. E. ZoBell and J. Stadler (both Univ. Wis.); and A Fermentation Calorimeter for the Study of Heat Evolution in the Decomposition of Plant Materials, by R. E. Carlyle and A. G. Norman (Iowa State Col.).

Studies on the Proactinomyces, W. W. UMBRETT. (N. J. Expt. Stas.). (*Jour. Bact.*, 38 (1939), No. 1, pp. 73-89).—This study of several well-defined species and many unidentified forms of the genus are believed to indicate that the criteria for its separation from the *Actinomyces* proper (absence of spore formation) are valid. Two subgroups are defined, and the relations of the lower limits of the genus to *Corynebacterium* and *Mycobacterium* are discussed.

Adaptation of the propionic-acid bacteria to vitamin B₁ synthesis, including a method of assay, M. SILVERMAN and C. H. WERKMAN. (Iowa State Col.). (*Jour. Bact.*, 38 (1939), No. 1, pp. 25-32, fig. 1).—The method of assay for

vitamin B₁ described is based on the increased anaerobic pyruvate metabolism of B₁-deficient cells of *Propionibacterium peniosaceum* on addition of this vitamin. If transferred continuously on a basal medium free of B₁ it can be adapted to synthesize this vitamin to satisfy growth requirements.

CO₂ utilization during the dissimilation of glycerol by the propionic acid bacteria, A. S. PHELPS, M. J. JOHNSON, and W. H. PETERSON. (Wis. Expt. Sta. et al.). (*Biochem. Jour.*, 33 (1939), No. 5, pp. 726-728).—"The report of [H. G.] Wood and [C. H.] Werkman² that the propionic acid bacteria utilize CO₂ during the dissimilation of glycerol has been confirmed."

Disintegration of the cell membrane of the cotton fiber by a pure culture of bacteria, F. E. HOOPER (*Contrib. Boyce Thompson Inst.*, 10 (1939), No. 3, pp. 267-275, figs. 3).—An aerobic bacterial rod capable of growing on inorganic media with such material as filter paper and cotton as the sole carbon source was isolated from the soil, studied in detail, and its disintegration of cotton fibers followed microscopically. The cuticle is removed early in the attack, and then both cementing material and cellulose are slowly digested. The particulate nature of the cellulose fibrils of the cell wall is clearly seen in the partially disintegrated fibers.

Leguminous plants and their associated organisms, J. K. WILSON ([*New York*] *Cornell Sta. Mem.* 221 (1939), pp. 48, pls. 10, fig. 1).—In this study emphasis was placed on the host-bacterial relationships and on the attempts by previous workers (17 references) to establish definite plant-bacterial groups. Methods developed for growing the symbionts together in closed containers provided a possibility of drawing rather definite conclusions. About 200 plant species in over 70 genera, and 32 *Rhizobium* strains, were used—isolated from a wide range of hosts and representing most of the host-bacterial groups that have been proposed. After examination of over 12,000 tests, the main conclusion drawn was that neither a sufficient number of plant species nor a sufficient number of diverse strains of bacteria have been employed previously in studying the comparative symbiotic relations to justify establishing definite plant-bacterial groups or to encourage use of those that have been proposed. This conclusion was reached because tests with the 32 *Rhizobium* strains representing most of these plant-bacterial groups indicated that many plants not assigned to any one of these groups could be placed in as many as 12 of them. Further support came from the fact that the boundaries surrounding plants from each proposed group also proved to be irregular. Data were also obtained indicating that many plants will symbiose simultaneously with several *Rhizobium* strains representing several plant-bacterial groups, while other plants are apparently somewhat restricted in this respect. Another conclusion is that plants which are promiscuous tend to symbiose with strains that are predominantly either monotrichic or multitrachic, while those which are restricted tend to symbiose only with the former.

The carbohydrate-nitrogen relation in legume symbiosis, P. W. WILSON and E. B. FENN. (Univ. Wis.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 6, pp. 497-502).—In reply to criticisms of Allison and Ludwig (*E. S. R.*, 81, p. 487), the advantages claimed for the carbohydrate-nitrogen hypothesis over the carbohydrate supply hypothesis are discussed in detail in that "it combines in a single hypothesis consideration of both supply of nitrogen and of carbohydrate and thus replaces both," and "the Ch:N relation has several definite measures of varying degrees of refinement, whereas the carbohydrate supply hypothesis has, in the past, employed such concepts as 'available carbohydrate' and 'metabolizable carbon' without specifying methods for their estimation." It is

² *Biochem. Jour.*, 30 (1936), No. 1, pp. 48-53.

believed to be an oversimplification to consider carbohydrate supply as the primary factor in legume symbiosis and to relegate the supply of nitrogen to the secondary role of serving as one method of control of carbohydrate. The point is stressed that the major requirement at this time for advancement in the understanding of legume symbiosis biochemistry is experimental facts. If any hypothesis suggests means for obtaining these facts, its use will be justified. There are 13 references.

Response of non-symbiotic nitrogen-fixing and nitrifying bacteria to different soil fertilization practices, J. L. ROBERTS (*Indiana Sta. Rpt. 1938*, p. 48).—This is a brief progress report.

Botanical aspects of soil conservation, R. O. WHITE (*Chron. Bot.*, 5 (1939), No. 2-3, pp. 180-182).—A review with citations.

New developments in our knowledge of how plants feed, L. D. BAYER. (Ohio State Univ.). (*Ohio Veg. and Potato Growers Assoc. Proc.*, 24 (1939), pp. 68-73).—A brief semipopular summary of recent findings relative to the way in which plants feed in soils.

Electrical response of *Phaseolus multiflorus* to electrical currents, W. S. REHM (*Plant Physiol.*, 14 (1939), No. 2, pp. 359-363, figs. 4).—It is shown that in *P. multiflorus* relatively small currents produce an effect dependent on the current direction, while stronger currents produce in the main axis and petioles an increase in basal positivity. It was previously demonstrated that decapitation produced a similar result (*El. S. R.*, 79, p. 309). Both phenomena indicate a latent oriented inherent mechanism capable of producing comparatively large electrical potentials roughly comparable to the situation in nerves and muscles. In the latter tissues stimuli produce an electrical response determined by an inherent oriented mechanism. The analogy suggests that this electrical response may play a part in the economy of the plant. It was also previously shown that in this plant there is an intimate relation between the orientation of bioelectric potentials and morphology. In this connection it is noted that the main electrical polarity of *P. multiflorus* was one of basal positivity.

Physico-chemical studies on the nature of cold resistance in crop plants (*Nebraska Sta. Rpt. 1938*, pp. 8-10).—A progress report, with particular reference to potato, nursery stock, wheat, and barley, and to the relation of bunt infection to hardiness.

Determination of constants for curves of water absorption by dry organic substances, C. A. and S. P. SHULL (*Plant Physiol.*, 14 (1939), No. 2, pp. 351-357).—Following up earlier studies of water absorption by dry organic matter such as seeds (*El. S. R.*, 44, p. 728) and gelatin disks (*El. S. R.*, 45, p. 525), the authors point out some of the details of the mathematical processes involved and illustrate the derivation of the original constants whereby approximate values may be obtained for the testing of fit.

The effect of dehydration on microsporogenesis in *Tradescantia*, N. GILES (*Amer. Jour. Bot.*, 26 (1939), No. 5, pp. 334-339, figs. 9).—The cellular water content of the buds was reduced during microsporogenesis by paraffin sealing of the cut ends of stems kept in water or by failing to water potted plants for several days. Such dehydration caused suppression of the spindle at one or both ends of the meiotic divisions, producing diploid and tetraploid microspores and pollen grains. The larger (probably octoploid) pollen grains occasionally noted are attributed to inhibition of the last premeiotic mitosis and both meiotic divisions. Cytokinesis by cell plate formation was also inhibited, in which case division by furrowing, not coordinated with nuclear division, often occurred. Nuclear without cellular division also occurred, producing bi- and quadrinucleate cells. Chromosome length in haploid microspores from buds of cut stems allowed

to wilt for 24 hr. was reduced to two-thirds the normal. These abnormalities are said to resemble those produced by many other agents (e. g., temperature, chemicals, and radiation), and to result from disturbance of the coordination of three apparently independent though normally synchronized events, viz, chromosome, nuclear, and cellular divisions. It is suggested that variations in the water supply may be important in producing polyploid gametes and consequently of polyploid races under natural conditions.

The relative humidity gradient of stomatal transpiration, H. F. THUR (*Amer. Jour. Bot.*, 26 (1939), No. 5, pp. 315-319, figs. 4).—This humidity gradient was demonstrated by measuring the relative humidity or equivalent of the leaf tissues and the humidity of the stomatal openings and intercellular spaces of normal well-watered and wilted plants, and the humidity of the external air. The tissue humidities were measured by the suction tension or diffusion pressure deficit method. Measurements of the humidity of the stomatal openings and intercellular spaces were made by noting the effects of various relative humidities on transpiration by exposing small parts of mature leaves over humidity bottles containing H_2SO_4 solutions or NaOH pellets, with the rest of the plant under usual laboratory conditions. The water loss from such leaves was an inverse linear function of the relative humidity, but in the region of high relative humidity water was absorbed from the bottles and not lost. The zero point of water loss from the leaves to the humidity bottles is interpreted as the relative humidity of the stomatal openings and intercellular spaces. The air humidity was measured by psychrometer.

A normal *Lantana* leaf showed a relative humidity of 99.4 percent in the tissues, 91 percent in the stomatal openings and intercellular spaces, and 40-48 percent in the external air. A wilted leaf gave respective humidities of 98.6 and 65 percent, with 40-48 percent for the air. Comparable results were obtained with bean, sunflower, and *Petunia*.

Relation of stomatal opening to water soaking of tobacco leaves. S. DIACHUN and W. D. VALLEAU. (Ky. Expt. Sta.). (*Amer. Jour. Bot.*, 26 (1939), No. 5, pp. 347-351, figs. 2).—Susceptibility to water soaking by a stream of water was determined largely by the degree of opening and condition of the stomata. With open stomata during the day the leaves could be water-soaked easily and rapidly, while with them nearly or quite closed at night the leaves became water-soaked only with difficulty. Wilting or shaded leaves water-soaked slowly, and the stomata here were found to be nearly or quite closed. Middle leaves of mature Burley plants water-soaked more rapidly than tip or basal leaves. Stomata were not fully developed on the tip leaves, while they were always nearly or quite closed on the basal leaves. It is suggested that the method here described and used may be adapted as an indirect method for studying stomatal behavior.

The morphological and cytological development of the sporophylls and seed of *Juniperus virginiana* L., A. C. MATHEWS. (Univ. N. C.). (*Jour. Elisha Mitchell Sci. Soc.*, 55 (1939), No. 1, pp. 7-62, pls. 9).—This paper includes a historical introduction (with 70 references), a description of materials and methods, and discussions of the detailed results of studies of the staminate cone and the microsporophyll, meiosis of the pollen mother cell and the fate of the microsporangial wall layers, pollination, the male gametophyte, the morphological development (including notes on the comparative morphology) of the ovulate strobilus, the stony layer, the megasporangium, the female gametophyte, fertilization, embryo formation, and the embryogeny of the Cupressineae and related groups.

Development and structure of the phloem tissue, K. ESAU. (Univ. Calif.). (*Bot. Rev.*, 5 (1939), No. 7, pp. 373-432, figs. 27).—The conclusions from this comprehensive review (nearly five pages of references) are that the modern concept of the phloem is that of a tissue containing highly specialized elongated enucleate cells with permeable cytoplasm, arranged in longitudinal rows and forming anastomosing strands together with the parenchymatous members. These specialized cells (sieve-tube elements or their counterparts) are intimately connected with one another. In most plants these connections are localized in wall areas occupied by sieve plates or by similar structures comparable to highly developed simple pits. The connecting strands are larger than ordinary plasmodesmata and are usually associated with variable amounts of callose in the wall region traversed. The parenchyma cells show different degrees of ontogenetic and physiologic relation to the sieve-tube elements. The angiosperm companion cells are most closely associated with the sieve-tube elements, then follow the albuminous cells of gymnosperms, and finally the phloem parenchyma and ray cells. When the sieve tubes reach maturity their protoplasts are in a premortal state. Thus these elements are rather short-lived, and the companion and albuminous cells die at the same time as the sieve tubes.

Phloem development and flowering, B. E. STRUCKMEYER and R. H. ROBERTS. (Wis. Expt. Sta.). (*Bot. Gaz.*, 100 (1939), No. 3, pp. 600-606, figs. 18).—In continuation of studies of anatomy in relation to flowering (*E. S. R.*, 77, p. 601), it was found from observations of the phloem of stems of a large number of plants that there are a greater number of sieve tubes and companion cells in the non-flowering than in the flowering stems and that these cells are also generally larger in the vegetative stems. Some of the phloem cells in flowering stems of many plants are crushed. The cambium in flowering stems of many plants becomes less active, and phloem parenchyma instead of sieve tubes and companion cells is formed. There is more callose in the phloem cells of flowering than of nonflowering stems. These characteristics were observed at the same time as the appearance of blossom primordia in several species.

Effect of photoperiod on development and metabolism of the Biloxi soy bean, M. W. PARKER and H. A. BORTHWICK. (U. S. D. A.). (*Bot. Gaz.*, 100 (1939), No. 3, pp. 651-689, figs. 17).—Biloxi soybeans with flower primordia initiated were transferred to photoperiods of 8, 10, 12, 13, 14, 15, 16, and 18 hr., and the development of these primordia and the flowering and fruiting responses determined. Plants transferred to 8- to 13-hr. days bloomed nearly simultaneously and produced fruits, but yields were somewhat less for the 8- than for the 10-, 12-, and 13-hr. lots. Flowering on the 14- and 15-hr. plants was later than for the shorter days, flowers were fewer, and no fruits developed. No flowers opened on the 16- and 18-hr. plants during the test period. When transferred to a range of photoperiods after flower primordium initiation, the longest day on which fruit formed was 13 hr., and the shortest one on which no flowers formed was 16 hr.

After initiation of flower primordia, plants were grown for biochemical studies on 8-, 13-, and 16-hr. days, with a control lot on a continuous 16-hr. day. At the end of a week's induction period the total nitrogen and soluble nonprotein N were higher in the 8-hr. plants than in the controls, but the carbohydrates were lower except for starch in the leaves which was higher. The total N in both stems and leaves of the 16-hr. transfers became similar to that of the controls, and the 13-hr. transfers approached the 8-hr. ones as the season advanced. The soluble nonprotein N showed the same relationship in the stems. There was an abrupt rise in ammonia in the leaves and stems of the 8- and 13-hr. transfers when pods began to form. The amount of soluble carbohydrates in the transfer

groups seemed to be correlated with the day length. Starch accumulated in the leaves and stems of the 8- and 13-hr. transfers when pods began to form. Two groups of plants with flower buds initiated and subsequently grown at day lengths just above and below the critical showed progressive deviation from each other in their carbohydrate and N metabolism. Those grown below the critical became similar to plants grown on an 8-hr. day, while those above the critical became similar to plants kept vegetative by continuous growth on a 16-hr. day.

Nitrogen nutrition in relation to photoperiodism in *Xanthium pennsylvanicum*. E. K. NEEDLE (*Bot. Gaz.*, 100 (1939), No. 3, pp. 607-618, fig. 1).—Plants in sand culture with very little or abundant nitrogen were first grown under long photoperiod, and then all were given an induction period of seven short photoperiods after which half were returned to long and half were left under short photoperiod. The latter group with abundant N bloomed first, those of this type with low N bloomed next, those under long photoperiod with high N were third, and those of this type with low N were fourth in time of blooming. Of the short-day plants, those with abundant N produced the greatest number of staminate heads, while all on long photoperiod produced more staminate flower clusters than those on short photoperiod. The percentage of abortive pollen was greatest in the short-day plants. In the latter a low N supply resulted in the greatest number of defective pollen grains, and in the long-day plants a high N supply had the same effect. There were more fruits per average plant in the short- than in the long-day plants. Under either short or long day, plants with abundant N had many more burs than those with a low supply. More seeds were found on the long-day plants, because many of the short-day plants had empty burs, many of the latter developing parthenocarpically. Plants grown under long-day treatment following an induction period with low N supply bore fruits and were larger than controls grown under long day with no induction period but with a similar low N supply. The latter bore no fruits.

Protein metabolism in the plant. A. C. CHERNAIL (*New Haven: Yale Univ. Press; London: Oxford Univ. Press, 1939, pp. XV+306, pls. 3, figs. 21*).—In this book the author's Yale University "Silliman Lectures" are presented in expanded form. The first four chapters discuss the question of protein metabolism in seedlings, consolidating the scattered contributions of many of the earlier investigators and attempting to show that their work cannot be viewed in true historical perspective except in terms of contemporary protein chemistry. Since this part is deemed of special interest to both biochemistry and plant physiology it is presented in considerable detail. The remaining chapters deal largely with the proteins of leaves and their metabolism, including considerable speculative material. The discussions here are grouped under the mechanism of amino acid and protein synthesis in plants, preparation of proteins from leaves, proteins of pasture plants, protein metabolism in leaves, the role of proteins in the respiration of detached leaves, and the regulation of protein metabolism in leaves. Appendixes take up the impurities in leaf-protein preparations and their bearing on the estimation of some amino acids; the estimation of nitrogenous bases, dicarboxylic acids, and amide nitrogen in the impure leaf-protein preparations; and the lipid fraction of chloroplasts.

Distribution of different nitrogen fractions, sugars, and other substances in various sections of the pineapple plant grown in soil cultures and receiving either ammonium or nitrate salts. C. P. SIDERIS, B. H. KRAUSS, and H. Y. YOUNG. (*Hawaii. Pineapple Prod. Expt. Sta.*). (*Plant Physiol.*, 14 (1939), No. 2, pp. 227-254, figs. 11).—Pineapple plants grown in nonsterilized soil weighed more when in cultures receiving ammonium than when receiving nitrate salts, but the chemical composition of the different sections of the leaves and

stems in both series tended to be about the same. The most outstanding result was the abundance of nitrate found in the stem and nonchlorophyllous basal leaf tissues of the leaves of plants receiving ammonium. The protein content of the leaves of plants in the nitrate series was slightly higher than in the ammonium group, but the soluble organic nitrogen was higher in plants of the ammonium series. As ammonium is assimilated very rapidly, inorganic N consisted mostly of nitrate, which was high in the stem and in the nonchlorophyllous sections of the leaves in both series. It is concluded that the chemical composition of plants grown in nonsterilized soil and receiving either ammonium or nitrate salts as N sources varies very little because of the conversion of ammonium to nitrate by the nitrifying bacteria of the soil.

Some remarks on the growth of the starch grain, N. P. BADENHUIZEN (*Chron. Bot.*, 5 (1939), No. 2-3, pp. 199-201).—A discussion and review.

Translocation of carbohydrates in the Outhbert raspberry, C. J. ENGARD. (Wash. State Col.). (*Bot. Gaz.*, 100 (1939), No. 3, pp. 439-464, figs. 4).—In this study, double rings (one 15 cm. and one 30 cm. above the ground) were used to check the movements of sugars in the stems. In normal plants the concentration of total carbohydrates proved to be fairly high in May, dropped during June, and became maximum in August, the acid hydrolyzable ones constituting the largest fraction. The reducing sugar content was highest in May, dropped rapidly in June, and increased slightly in July and August. A low concentration of sucrose was present at all times, but starch was never abundant and apparently is not an important reserve. In ringed plants the total carbohydrates accumulated above the rings, and decreased below and between them. Sucrose made the largest increase above the rings, and reducing sugars accumulated above but decreased between and below them. Sucrose apparently tended to move upward as well as downward in the bark. It does not appear to result from hydrolysis of hemicellulose in the isolated segment as do the reducing sugars. A part of the reducing sugars is translocatory, moving downward in the bark. All carbohydrate gradients were positive. Sugars moved downward with a marked positive gradient. The positive gradients of the acid hydrolyzable substances and of starch were static. These gradients are produced by temporary storage. Ringing decreased the positive gradients of reducing sugars, indicating that some of them are mobile in the bark along a dynamic positive gradient. Much of the reducing sugars may be in temporary storage forms. Therefore, their positive gradient results from a positive dynamic gradient of reducing sugars and a positive static gradient of temporary storage sugars. The insignificant gradient of sucrose is increased rather than decreased, as would be expected if this sugar were moving only downward. The residual substances consisted of those polysaccharides, small amounts of fats, minerals, and organic nitrogen which remained after the total carbohydrates were subtracted from the dry weight. The residual polysaccharides are believed to include the "intussusception" material (polysaccharides of high molecular weight and their derivatives) of the cell wall. They fluctuate as the total carbohydrates (particularly reducing sugars and the "hemicelluloses") fluctuate, and in the same direction. There are 32 references.

Carbohydrate and respiratory metabolism in the isolated starving leaf of wheat, G. KROTKOV (*Plant Physiol.*, 14 (1939), No. 2, pp. 203-226, figs. 12).—"Data are presented on the changes in the rate of CO₂ emission and in the content of simple and complex sugars which proceed in the cells of isolated, first foliage leaves of wheat starving in the dark. The dual form of the highly characteristic changes in the rate of CO₂ emission is shown to have its origin in the degradation of two categories of substances to yield respiratory substrate. The

two categories are the original primary reserve of sugars on the one hand, and on the other a variety of substances, some of which are of significance in protoplasmic organization. The manner of depletion of reserve sugar controls the course of starvation metabolism in its early stages. The depletion of secondary substrate materials guides the metabolic drift in the later stages and finally causes it to terminate suddenly in autolytic disorganization." There are 13 references.

The chlorophyll-carbon dioxide ratio during photosynthesis, E. D. MCALISTER (*Jour. Gen. Physiol.*, 22 (1939), No. 5, pp. 615-636, figs. 9; *abs. in Chron. Bot.*, 5 (1939), No. 2-3, pp. 156, 157, figs. 4).—Using a method of CO₂ measurement described before (E. S. R., 77, p. 453), the time course of photosynthesis was further studied on Marquis wheat. A highly important finding was that immediately after a high rate of photosynthesis there is a pick-up of CO₂ in darkness believed to be due to the action of a CO₂-combining intermediate—the "acceptor molecule" for CO₂ in photosynthesis. The observed conditions appear to indicate that this intermediate is formed in relatively large amounts during but not before photosynthesis, and that it is of chlorophyllous nature. Further studies of the induction phase under various conditions of previous dark rest and of CO₂ and light limitation are believed to indicate that chlorophyll participates in photosynthesis as an individual molecule and not as part of a very large multimolecular chlorophyll unit. The fast dark reaction lasting about 1 min. required to produce both the phenomena of induction in CO₂ assimilation and the recovery of fluorescence of chlorophyll shows a close relationship between chlorophyll fluorescence and induction in photosynthesis. The respiration rate of wheat was measured under intense illumination and in the absence of CO₂ to suppress assimilation. This value was found to be identical with the dark respirational rate measured before and after the light period, indicating the absence of any direct effect of light on respiration.

Condition of chlorophyll in the leaf, O. L. INMAN and M. L. CROWELL (*Plant Physiol.*, 14 (1939), No. 2, pp. 388-390, figs. 2).—The authors studied the physical and chemical states of chlorophyll after grinding *Trifolium repens* leaves with sand, extracting with buffer, filtering, and centrifuging so that only the colloidal material was retained as the triturate. From the results of treatment with trypsin and CO₂ it is concluded that trypsin probably causes Mg to be freed from the chlorophyll molecules with formation of pheophytin, and makes the chlorophyll molecules of the triturate more susceptible to displacement of the Mg by addition of CO₂. No pheophytin formation was observed when the triturate was definitely alkaline. One plausible assumption advanced is that the chlorophyll pigments may be bound to their substrate through a Mg-protein linkage.

Organic acid metabolism of the buckwheat plant, G. W. PUCHER, A. J. WAKEMAN, and H. B. VICKERY. (Conn. [New Haven] Expt. Sta. et al.). (*Plant Physiol.*, 14 (1939), No. 2, pp. 333-340).—Oxalic, malic, and citric acids were found to make up ± 90 percent of the organic acids of the leaf and ± 72 percent of those in the stem, oxalic predominating, malic being present in relatively smaller amounts, and citric acid in minor proportions. The leaves of one plant contained ± 1.5 times as much total acid as the stem. During maximum illumination photosynthesis was most active and the organic acids increased, though there was a decrease in H-ion activity of the sap in the stem. In the later part of the day malic acid was utilized and there was an increase in the unknown organic acids. The net change in the total organic acids was a small increase, but the H-ion activity of the sap of the stem increased to about the early morning level. Photosynthesis was much less active in this

period, and inorganic-ion assimilation from the culture solution was also depressed. During the night there was a small increase in total organic acids and a marked interconversion of unknown acids into one or more of the known acids. There was no change in H-ion activity in the sap of the stem. The evidence is believed to indicate that interpretations of the changes in H-ion activity of the sap in terms of an increase or decrease in organic acids cannot be made in the absence of specific information regarding these substances. It is deemed obvious that such factors as absorption of inorganic ions by the roots and the distribution of the inorganic and organic basic constituents within the tissues, as well as photosynthesis, play an important role in the acidity changes occurring. There are 16 references.

An electro-chemical theory of salt absorption and respiration, H. LUNDEGÅRDH (*Nature [London]*, 143 (1939), No. 3614, pp. 203, 204).—The theory of "anion respiration" here presented and outlined refers to cells with a pronouncedly acid protoplasmic membrane, which seems to be characteristic of plant roots though other kinds of cells may behave differently. Potential gradients in protoplasmic boundaries are believed to be of fundamental importance in both the metabolism and translocation of substances within the organism. From this viewpoint the investigations of ion absorption by roots may have a wider application.

Metabolism and salt absorption by plants, D. R. HOAGLAND and F. C. STEWARD. (Univ. Calif. et al.). (*Nature [London]*, 143 (1939), No. 3633, pp. 1031, 1032).—A critique of Lundegårdh's theory, noted above.

Upward and lateral movement of salt in certain plants as indicated by radioactive isotopes of potassium, sodium, and phosphorus absorbed by roots, P. R. SROUT and D. R. HOAGLAND. (Univ. Calif.). (*Amer. Jour. Bot.*, 26 (1939), No. 5, pp. 320-324, figs. 2).—Radioactive isotopes of K, Na, P, and Br were used to study the upward movement of salts in actively growing and transpiring willow and geranium, after absorption by their roots. The technic of isolating a strip of bark from the wood was followed, in which these substances moved extremely slowly. Within short periods no definitely significant amount of radioactivity was detected in the central section of the strip, while large amounts were found in the wood. However, where wood and bark were in contact, radioactive elements were rapidly transferred laterally from wood to bark. This evidence is deemed consistent with the view that the xylem is the path of rapid upward movement of salts.

Differential distribution of ash in stems of herbaceous plants from base to tip, A. E. EDGECOMBE (*Amer. Jour. Bot.*, 26 (1939), No. 5, pp. 324-328).—Six herbaceous species were grown 4 mo. under uniform greenhouse conditions. Spring and winter plants were examined separately for comparisons, all tests were in duplicate, composite samples from specific stem regions were used, and the water content was calculated from the wet and dry weights. Stem-tissue samples from base to tip of plant showed an increasing ash gradient on the dry-weight basis and a decreasing ash gradient and an increasing water gradient on the wet-weight basis. The ash and water gradients of these plants were in general the reverse of those found for worms, except for the ash content on the dry-weight basis which was similar. However, the ash content on the dry-weight basis and the water content on the wet-weight basis for both plants and worms were correlated with the metabolic gradient and paralleled the direction of growth. Except for the ash gradient on the wet-weight basis, the ash and water gradients of these plants were in the main of the same order and direction as those found for rose plants.

Transport of inorganic ions in polar plant tissues, F. W. WENT (*Plant Physiol.*, 14 (1939), No. 2, pp. 365-369).—Studying the transport of some radioactive elements in polar plant tissues by two types of experiment described, it was found that in the same tissues simultaneously there occurs a polar auxin transport and a nonpolar movement of inorganic ions. Thus it is believed that there is no escape from the idea that the movements of auxin and of Na^+ , Br^- , and PO_4^- are controlled by completely different mechanisms. This may be viewed as a fundamental difference in the locomotor mechanism for the movement of these substances, or simply as a difference in the path of transport. Whatever the explanation, it is deemed clear that the accumulation mechanism for inorganic ions and the polar transport mechanism for auxin are not identical and must be located in different parts of the cell.

Experiments with different quantities of iron salts given to maize in water culture, C. OLSEN (*Compt. Rend. Lab. Carlsberg, Sér. Chim.*, 21 (1938), No. 23, pp. 301-313, fig. 1).—Optimum growth of maize in a modified Knop solution at pH 4 was obtained by adding comparatively small amounts of iron, while addition of considerably larger quantities acted toxically. The Fe content of the leaves and stems rose with increasing amounts of added Fe, and more especially when FeSO_4 was used. When grown in a nutrient solution at pH 7, the relatively small amounts of Fe producing optimum growth at pH 4 gave plants which were much dwarfed and chlorotic, and not until larger amounts of Fe were given did optimum growth ensue. With amounts of Fe producing optimum growth, plants grown in solutions at pH 7 produced dry matter weighing considerably more than the greatest amount produced in solutions at pH 4. However, the largest amounts of FeSO_4 and ferric citrate used in the tests were toxic, even at pH 7. On the other hand, it was not found possible to add enough $\text{Fe}_2(\text{SO}_4)_3$ to solutions at pH 7 to produce toxic action, and the greatest production of dry matter obtained during the study resulted from adding the greatest amount of $\text{Fe}_2(\text{SO}_4)_3$ to the solution. The greater toxicity of the ferrous ions to maize is explained on the basis that their solubility is considerably greater than that of the ferric ions. Ferric citrate is said to be especially suitable as a source of Fe for plants in water culture, but should be added at intervals rather than all at once. With mustard, however, it was found necessary to use $\text{Fe}_2(\text{SO}_4)_3$ in addition to ferric citrate to maintain satisfactory growth.

The essentiality of certain elements in minute quantity for plants with special reference to copper, D. I. AENON and P. R. STOUT. (Univ. Calif.). (*Plant Physiol.*, 14 (1939), No. 2, pp. 371-375).—This is a critical review (13 references) of more recent studies of the so-called minor elements and their significance in plant metabolism, with discussions of difficulties involved, warnings as to possible sources of error, and with special reference made to studies by the authors (*E. S. R.*, 81, p. 352).

Relations of plants to minute doses of inhibitive substances, E. S. REYNOLDS (*Plant Physiol.*, 14 (1939), No. 2, pp. 385-387).—The author refers to the results of various investigators with growth substances and traces of mineral salts as showing a stimulatory action when used in minute doses, though becoming inhibitory or toxic in larger quantities. Accommodation to increased or decreased amounts is also noted. Recent observations here detailed relative to oleander cuttings in solutions of heteroauxin are said to have indicated the same type of reactions. These phenomena are briefly discussed, and it is concluded that in any case this preliminary inhibition and final stimulation of plant tissues by toxic substances, thus indicating an accommodation of the

organism to them, points to the necessity of a more careful consideration of such phenomena in physiological studies.

The minor element problem in Ohio greenhouses, I. C. HOFFMAN. (Ohio Expt. Sta.). (*Ohio Veg. and Potato Growers Assoc. Proc.*, 24 (1939), pp. 51-55).—A general discussion of Mn, Mg, and Fe deficiency in greenhouse-grown vegetables.

Responses of plants to growth substances applied as solutions and as vapors, P. W. ZIMMERMAN, A. E. HITCHCOCK, and F. WILCOXON (*Contrib. Boyce Thompson Inst.*, 10 (1939), No. 3, pp. 363-376, figs. 2).—A review (27 references) of plant responses to growth substances applied in solution and to unsaturated carbon gases is presented. In this study, tomato, corn, Klondike cosmos, marigold, girasol, mimosa, *Chenopodium*, and garden pea responded to 29 compounds applied as vapors which were physiologically active as growth substances when applied in solution, characteristic reactions being induced with exposures as short as 30 sec. The well-known "triple response" of etiolated pea seedlings commonly associated with the effect of ethylene gas was induced with vapors of 17 growth substances. Excessive elongation of etiolated coleoptiles and mesocotyls and pronounced curling and swelling of the internodes of corn occurred on exposure to vapors of these substances in either light or darkness. The similarities in responses induced by the unsaturated hydrocarbon gases and by vapors of growth substances are discussed.

The relative activities of different auxins, K. V. THIMANN and C. L. SCHNEIDER (*Amer. Jour. Bot.*, 26 (1939), No. 5, pp. 323-333, figs. 4).—The growth-promoting activities of six pure auxins were compared with that of indole-3-acetic acid, and the ratio of the activity as determined by any method with that of this acid was termed the "relative activity." Relative activities for straight growth as determined for *Avena* coleoptiles differed from those for *Pisum* internodes, and the differences are not believed due to differences in carbohydrate supply. In *Pisum* the values for straight growth differed from those for slit stem curvatures, which is explained on the basis of differential sensitivities of the tissues. With any of the methods the values also varied somewhat with the sensitivity of the plants on the day of the test. By taking the average of several series of tests with each method, approximate relative activities were derived and tabulated.

Experiments on the transport of auxin, F. W. WENT and R. WHITE (*Bot. Gaz.*, 100 (1939), No. 3, pp. 465-484, figs. 10).—Adapting the photokymograph recording of the *Avena* test in a new technic, the results of H. G. van der Weij³ were, in general, confirmed, as far as the transport properties of *Avena* coleoptiles are concerned. The velocity was independent of length of tissue, but the amount transported decreased with increased length of coleoptile section. Transport through the narrow or wide side of a coleoptile was practically the same, but the lower part had transport properties differing slightly from the more apical zones. The polarity of indoleacetic acid transport was far more pronounced than most of the earlier investigators found. In the present studies leakage along moist surfaces was more nearly excluded. Only the highest auxin concentrations (1,000 mg./l.) were transported from base toward top through 3.1 and 4.2 mm. sections, but not through 6.3 mm. coleoptile sections. There were great differences in transport rate among various growth substances. Owing to this and to differences in rate of growth reaction and limited transport capacity of the coleoptile cells, a wide variation resulted in the apparent growth activity of these substances in the *Avena* test. Indoleacetic acid transport

³ Rec. Trav. Bot. Néerland., 29 (1932), pp. 379-496, figs. 26.

through other plant tissues was determined, with positive results for corn coleoptile, papaya leaf stalks and midribs, *Tropaeolum* leaf and flower stalks, and *Nitella* internodal cells.

Effect of indole-3-acetic acid on photosynthesis, N. G. CHOLODNY and A. G. GORBOVSKY (*Science*, 90 (1939), No. 2324, p. 41).—From the experiments with various plants (lilac, poplar, jasmine, hemp, hydrangea, etc.) briefly reported, it is concluded that indole-3-acetic acid causes a temporary intensification of photosynthesis on being directly introduced into the assimilating tissues of green leaves in very low concentrations.

Growth and metabolism of bean cuttings subsequent to rooting with indoleacetic acid, J. W. MITCHELL and N. W. STUART. (U. S. D. A.). (*Bot. Gaz.*, 100 (1939), No. 3, pp. 627-650, figs. 6).—Treatment of kidney bean cuttings with 0.01 percent indoleacetic acid under the experimental conditions described significantly increased the weight of the hypocotyls and roots over those of controls until the thirteenth day after treatment. It also significantly decreased the growth of the first internode throughout the experiment, and also the growth of the tips. Even a strong solution (0.01 percent) did not appreciably affect the dry weight of the primary leaves. A weak solution (0.002 percent) caused slight responses qualitatively like the strong solutions. Neither strong nor weak treatment increased the weight of the whole plants above the controls. During rooting nitrogen was transported from the leaves to the first internodes and hypocotyls, the strong solution being by far the most effective in increasing the amount mobilized. This N was subsequently translocated to other parts of the cuttings. With the 0.01 percent solution a large amount of this mobilized N was temporarily deposited in the hypocotyls in insoluble form, but later was translocated to other parts of the cuttings. Since all this N later disappeared, it is deemed evident that the treatment stimulated the proteolytic enzyme activity of the cuttings. Applying nutrient solution after rooting increased the N content of the cuttings by ± 35 percent. The larger number of roots induced by treatment resulted in the uptake of only a slightly larger amount of N and inorganic substances than were absorbed by the controls. Treatment with 0.002 percent acid resulted in slightly greater accumulation of sugars than in controls at the end of the experiment, while the 0.01 percent acid significantly reduced the sugar content of cuttings below that of controls at all times. No starch was present at any time in roots, leaves, or tips, and only traces in the hypocotyls and first internodes. Interpretation of the carbohydrate metabolism in relation to growth is said to require further information as to the effect of the acid on the rates of photosynthesis, respiration, and enzyme activity.

Effects of indoleacetic and naphthylacetic acids on development of buds and roots in horseradish, R. C. LINDNER (*Bot. Gaz.*, 100 (1939), No. 3, pp. 500-527, figs. 14).—"In the young horseradish root, lateral roots develop from the pericycle or its derivatives, resulting in crushing of the endodermis. In the mature root, or transverse segments of it, buds originate in the region where the cambium of the upper root traces comes in contact with the phellogen. Roots originate from lower root traces in a similar manner. Derivatives of the cambium, phellogen, pericyclic parenchyma, phloem parenchyma, and xylem parenchyma may all be involved in the development of buds and roots. Occasionally a root may be formed from the lower cut surface without a root trace being involved. Application of relatively high concentrations of indoleacetic and naphthylacetic acids inhibits shoot production and stimulates root production. Under the influence of these compounds, roots are organized in the regions where buds would otherwise have organized. In addition, the mor-

phologically lower cut surfaces of the treated segments produce numerous roots from derivatives of the wound phellogen, phloem parenchyma, xylem parenchyma, and cambium. There is no root organization from the upper cut surface unless a lateral root trace is involved. Peripheral application of indoleacetic or naphthylacetic acid induces activity in the outer parenchymatous cells of the root, which culminates in the formation of new roots that soon perish. Placing the cut segments in running water for 24 hr. before treatment inhibits the production of callus and results in an increased invasion by micro-organisms. Various extracts of the horseradish plants were ineffective in the stimulation of the production of buds." There are 25 references.

Inhibition of the growth of buds of potato tubers with the vapor of the methyl ester of naphthaleneacetic acid, J. D. GUTHRIE (*Contrib. Boyce Thompson Inst.*, 10 (1939), No. 3, pp. 325-328, fig. 1).—This ester inhibited the growth of potato tuber buds and was sufficiently volatile at room temperatures to be introduced as a vapor into intact tubers. Sprouting was retarded by storage in the presence of paper impregnated with the ester, and growth of the buds was inhibited by storage of tubers in a paper bag previously sprayed with it inside. This ester also induced epinasty of tomato leaves when a piece of filter paper containing a small amount was placed under a bell jar with the plant.

Studies in breaking the rest period of grass plants by treatments with potassium thiocyanate and in stimulating growth with artificial light, H. R. SHEPHERD. (Kans. State Col.). (*Kans. Acad. Sci. Trans.*, 41 (1938), pp. 139-153, figs. 9).—Some sods of five midwestern grasses (*Bouteloua gracilis*, *B. curtipendula*, *Buchloe dactyloides*, *Agropyron smithii*, and *Andropogon furcatus*) were treated with potassium thiocyanate, some were subjected to outdoor freezing, and then some of each of these lots were given supplemental light in an attempt to break their rest periods and to stimulate growth. The rest periods of *Bouteloua gracilis* and *B. curtipendula* were effectively broken 21 days after the chemical treatment, and a slight response also occurred in *Andropogon furcatus*, the most effective concentration of the thiocyanate being a 0.1 percent solution. The rest period of *Buchloe dactyloides* was not broken by the chemical treatment. *Agropyron smithii* appeared to have no rest period. In most instances the grasses were stimulated to greater growth in height by the chemical and supplemental light treatments. In the majority of cases 2 and 1 percent concentrations of chemical killed the plants. Chemical treatment seemed to inhibit the flowering of *B. dactyloides*, while supplemental light was conducive to flowering in *Bouteloua gracilis*. All plants frozen out of doors began active growth 4 days after having been brought inside on December 30, and in nearly all cases they had made as much growth by the end of the experiment as had the treated plants.

Oxygen regulates the dormancy of the potato, N. C. THORNTON (*Contrib. Boyce Thompson Inst.*, 10 (1939), No. 3, pp. 339-361, figs. 4).—It is reported that newly harvested potatoes will sprout in 7 days if held in 5-10 percent O_2 under moist conditions and in 9 days if held in 2 percent O_2 under dry conditions, but that sprouting will not occur until 47 days later if held in 20 percent O_2 , an excessive amount. Moist conditions facilitate and dry conditions retard the formation of periderm. The detailed results obtained and the theoretical bases for them are fully discussed, and it is concluded that the experimental results and observations presented are contrary to the generally accepted theories regarding dormancy in newly harvested potatoes. It is shown that dormant potatoes fail to sprout because the bud tissue obtains too much O_2 rather than an insufficient supply, that the skin of young tubers is more rather than less

permeable to O_2 , that the tuber skin becomes less rather than more permeable with age, and that peeling or otherwise wounding dormant tubers induces a condition retarding rather than facilitating the entrance of O_2 . There are 14 references.

Cytology of dormancy in Phaseolus and Zea. F. G. MIDDENDORF (*Bot. Gaz.*, 100 (1939), No. 3, pp. 485-499, figs. 19).—Fixed in various fluids and stained by both iron hematoxylin and the Feulgen reaction, the cell in dormant seeds was plasmolyzed and the nucleus had an irregular form, apparently lacking membrane or limiting structure. The nucleolus was not optically differentiated by fixation, although it may stain intensely with iron hematoxylin. The vacuoles were small, and the mitochondria were small granules or spheres. At germination the cell became turgid, the nucleus regained a normal spherical form and the boundary became definite, and the nucleolus became optically differentiated even when unstained as by the Feulgen reaction, showing a vacuolate structure. The cytoplasmic vacuoles enlarged, and the mitochondria elongated into rods or filaments. Prior concepts regarding the chromatin of the dormant cell as having migrated centrifugally or centripetally are rejected on the basis of the Feulgen reaction. There are 24 references.

The use of indicator plants in locating seleniferous areas in western United States.—II, Correlation studies by States, O. A. BEATH, C. S. GILBERT, and H. F. EPPSON. (Wyo. Expt. Sta.). (*Amer. Jour. Bot.*, 26 (1939), No. 5, pp. 296-315, fig. 1).—Continuing the investigation (E. S. R., 81, p. 354), this study of 563 specimens of native plants collected from 12 western States included the geographical location, geological formation and age of rock or soil on which the specimen was growing, stage of growth of the plant, part of the plant analyzed, and selenium concentration in parts per million. Special attention was accorded species of *Stanleya*, *Astragalus*, *Oenopsis*, and *Xylorrhiza*, the first two, because of wide distribution, proving especially valuable as indicators. Practically all specimens of *Stanleya* proved to be seleniferous, while the seleniferous species of *Astragalus* were restricted to 5 of the 29 groups of the Jones classification. These studies are believed to demonstrate that numerous geological formations from late Paleozoic to Quaternary can support native seleniferous plants, which are found rooted in both igneous and sedimentary rocks. The rocks include monzonite, limestones, and various shales. A number of geographical areas and geological formations not previously reported are considered. There are 22 references.

GENETICS

Breeding resistant races of crop plants [trans. title], E. SCHIEMANN (*Chron. Bot.*, 5 (1939), No. 2-3, pp. 161-165).—A review with citations.

The centromere, D. G. CATCHESIDE (*Chron. Bot.*, 5 (1939), No. 2-3, pp. 160, 161).—A description and discussion of the functions of this specialized particle in the chromosome which is said to determine not only normal chromosome movement but, through errors in its own division, may lead to the production of chromosomes having a new composition.

The nomenclature of hybrids, H. H. ALLAN (*Chron. Bot.*, 5 (1939), No. 2-3, pp. 205-209).—A discussion of the international rules.

The nomenclature of hybrids, T. A. SPRAGUE (*Chron. Bot.*, 5 (1939), No. 2-3, pp. 209-212).—A discussion of the foregoing.

Reflections on the nomenclature of so-called hybrids, H. UITTEN (*Chron. Bot.*, 5 (1939), No. 2-3, pp. 212-214).—A discussion of the two foregoing.

Studies of inheritance in crosses between Bond, *Avena byzantina*, and varieties of *A. sativa*, H. K. HAYES, M. B. MOORE, and E. C. STAKMAN (*Minne-*

sota Sta. Tech. Bul. 157 (1939), pp. 38, figs. 6).—Correlated studies were made on the manner of inheritance of characters differentiating varieties of *A. byzantina* and *A. sativa* and reaction of these oats varieties to stem rust, crown rust, and smuts. The material comprised crosses between Bond, *A. byzantina*, and several varieties of *A. sativa*, including Anthony, Iogold, Rainbow, and two selections called Double Cross A and Double Cross B, respectively, from previous crosses of (Minota×White Russian)×Black Mesdag.

Stem rust resistance was dominant to susceptibility, with a single factor difference indicated. Bond proved resistant to all physiological races of crown rust used. F_1 of all crosses proved resistant although lower in degree of resistance than Bond. F_2 of Bond×Rainbow approached a ratio of three resistant to one susceptible, indicating a single factor difference, while the other crosses gave segregations of nine resistant to seven susceptible, indicating two major factors for differentiation. Bond and the Double Crosses A and B proved resistant to the smuts in the field, the factor or factors conditioning resistance being unlike in Bond and Double Cross A. In crosses of Bond with Iogold and Anthony there were indications of a single major factor difference and some evidence of minor modifying factors. Previous studies indicated that at least two major factors were needed to explain resistance of the Black Mesdag type as exhibited in the double crosses used.

In mode of separation of the lower floret of the spikelet from the axis of the spikelet, the *A. sativa* type of abscission appeared dominant (3:1) over the *A. byzantina* type, designated as disarticulation, while the method of floret disjunction characterized by *A. byzantina* is dominant over the *A. sativa* type. Floret disjunction of *A. sativa* varieties usually showed disarticulation at the apex of the rachilla segment; the double crosses were characterized by heterofracture; and Bond showed disjunction by basifracture. Segregation in crosses between Bond and the double crosses was explained on the basis of a single major factor difference and more than one factor in the other crosses. Bond usually had a heavy growth of basal hairs on the lower floret, while the *A. sativa* varieties showed fewer or no basal hairs. *A. sativa* type of basal hairs behaved as a simple dominant over the Bond type. The type of segregation in awn development was strongly influenced by characteristics of the parents used in the crosses. Bond surpasses all other varieties in plumpness of seed, which could be transferred to plants typical of *A. sativa*.

Independence or association of characters in the F_2 generation of crosses was studied by means of χ^2 and P. One of the five crosses showed a negative association between degree of crown rust infection and plumpness of seed, and two crosses showed a similar association between plumpness of seed and degree of stem rust infection. Spikelet disarticulation was associated strongly with shattering of seed, with type of floret disjunction, and with type of basal hair development. Basal hair development was associated strongly with floret disjunction and awn development. Association between spikelet disarticulation and basal hair development was explained on the basis of genetic linkage with a cross-over value of 2.7 ± 0.3 . Indications were that it should be relatively easy to combine resistance to stem rust, crown rust, and the smuts with characters of cultivated varieties of *A. sativa* and with the plumpness of grain characterizing Bond oats.

Genetics of barley, D. W. ROBERTSON. (Colo. Expt. Sta.) (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 4, pp. 273-283, figs. 12).—The linkage of characters in the common cultivated barleys, *Hordeum vulgare*, *H. intermedium*, *H. distichum*, and *H. deficiens*, all reported to have seven haploid chromosomes, are discussed with regard to the reported seven linkage groups, in which two or

more characters have been located. Short descriptions of some of the newer characters are given.

Mutants and linkage studies in *Triticum monococcum* and *T. aegiloides*, L. SMITH. (Coop. U. S. D. A.). (*Missouri Sta. Res. Bul.* 298 (1939), pp. 26, figs. 22).—Supplementing the information recorded earlier (E. S. R., 77, p. 316), descriptions are given for 56 viable mutants, mainly from X-rayed material. Absence of linkage was indicated by 97 combinations of factors, whereas 9 pairs of factors were linked, 4 (involving 6 genes) closely or completely.

Natural crossing in beans at different degrees of isolation, K. C. BARBONS. (Aia. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), pp. 637-640).—Preliminary experiments having shown 2.7 percent of natural crossing between bush varieties of common bean and 5.11 percent between pole varieties, strains of lima and common beans possessing contrasting characters were grown 1, 2, 3, 5, and 9 yd. apart. The percentages of natural crossing were 5.03, 2.51, 3.24, 2.27, and 1.10, respectively, in the lima varieties, and 8.26, 7.52, 4.9, 4.78, and 2.63 in the common bean. As a result, the author adopted the practice of isolating parental stocks by 50 yd. or more.

Immunity to *Fusarium* wilt in the tomato, G. W. BOHN and C. M. TUCKER. (Univ. Mo.). (*Science*, 89 (1939), No. 2322, pp. 603, 604).—This preliminary statement reports that tests of several thousand plants in various progenies from crosses between an apparently immune Peruvian strain of *Lycopersicon pimpinellifolium* and several susceptible commercial tomato varieties prove that immunity to *F. lycopersici* in tomatoes depends on one dominant genetic factor. This factor was maintained in the heterozygous condition in a series of four backcrosses to susceptible varieties, and its potency was not decreased in the fourth backcrosses or their progenies. Large fruit size and other commercially valuable characters were obtained in some plants of advanced generations, and preliminary tests indicated that some plants in progenies from self-pollinated flowers of selections derived through outcrossing immune selections to commercial sorts for four generations were homozygous for immunity. Various lines are being tested and subjected to further selection.

Further data on breeding mosaic-escaping raspberries, C. D. SCHWARTZ and G. A. HUBER. (Wash. Expt. Sta.). (*Phytopathology*, 29 (1939), No. 7, pp. 647, 648).—Further experimental data (E. S. R., 80, p. 504) indicated that the mosaic-escaping Lloyd George variety carries at least two genetic factors for resistance to the vector *Amphorophora rubi*, whereas plants that are somewhat resistant carry fewer resistance factors and susceptible ones are homozygous recessives.

The guinhen: Hybrid resulting from crossing a guinea hen and a male chicken, E. M. FUNK. (Univ. Mo.). (*Amer. Poultry Jour.*, 69 (1938), No. 10, p. 16, figs. 4).—Four hybrids between Pearl guinea hens and a Rhode Island Red rooster are described. The hybrids had yellow skin, the plumage showed some red color, and the combs were absent. Guinea shank color predominated.

Factors affecting fertility in Rhode Island Reds, F. A. HAYS and R. SANBORN. (*Massachusetts Sta. Bul.* 359 (1939), pp. 15, fig. 1).—Study was made of the effects of various factors on fertility in the Rhode Island Red flock from 1922 to 1936. Fertility rose with temperature variations until outside temperature was about 37° F. The fertility of both males and females declined with age, but males were mainly responsible for infertile matings. Variations in the number of females from 1 to 14 with which males were mated had no effect upon the fertility record. There was no correlation between fertility of dams and their daughters, suggesting that fertility was not heredi-

tary. However, the percentage of fertile matings within and between different families varied.

Growth of the hen's ovum, D. C. WARREN and R. M. CONRAD. (Kans. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 58 (1939), No. 12, pp. 875-893, figs. 7).—Ovum growth rate was studied by intravenous injections of Sudan III into Single Comb White Leghorns and Rhode Island Reds, and observations were made on 367 eggs laid. From the dye bands growth rate was ascertained and the comparative influences of rate of laying, clutch position, and other factors were determined. Growth was relatively constant as measured by radius increments from the ninth to the seventh day before ovulation but decreased rapidly thereafter, although some growth was detectable within an hour of ovulation. The first egg of the clutch may continue its growth slightly longer than successive eggs, but variations in yolk size and rate of ovulation were not conditioned by rate of ovum growth. The physiological basis for this is probably associated with factors controlling the initiation of the final stage of accelerated growth. Feeding excessive amounts of egg yolk stimulated rate of yolk secretion and increased the size of the mature ovum, but kamala feeding disturbed and checked the process of yolk secretion and thereby affected egg size.

Lactogen content of the anterior pituitary of growing rabbits and guinea pigs, S. HOLST and C. W. TURNER. (Mo. Expt. Sta.). (*Soc. Expt. Biol. and Med. Proc.*, 41 (1939), No. 1, pp. 198-200).—A comparison of the lactogen content in the anterior pituitary of mature females of different species showed the guinea pig to rank first with about 600 bird units per gram, the albino rat second with about 500 bird units, and the rabbit third with about 300 bird units. The lactogen content in the anterior pituitary of male rabbits was found to be very low and almost constant in all stages of growth and adult life, while that in the male guinea pig increased rapidly at puberty, exceeding the content of the mature nonlactating female of the species.

Skeletal changes and blood serum calcium level in pigeons receiving estrogens, C. A. PFEIFFER and W. U. GARDNER (*Endocrinology*, 23 (1938), No. 4, pp. 485-491, figs. 14).—In studies at Yale University, daily injections of 1,000 International Units of oestrogen into pigeons caused a rise in serum calcium from a normal of 8 to 8.8 mg. per 100 cc. of serum to values ranging from 13.12 to 21.65 mg. Hypercalcification of the marrow-containing bones began about 2 weeks after such injections were started and reached a maximum after 5 weeks. Most of the new bone was endosteal.

Hypercalcification, -calcemia, and -lipemia in chickens following administration of estrogens, W. LANDAUER, C. A. PFEIFFER, W. U. GARDNER, and E. B. MAN. ([Conn.] Storrs Expt. Sta. et al.). (*Soc. Expt. Biol. and Med. Proc.*, 41 (1939), No. 1, pp. 80-82).—In further studies, full-grown sexually mature cocks received daily injections of oestrogen ranging from 1,700 to 30,000 International Units. After 3 weeks' injection at the lower level a thin layer of newly deposited calcium was found on the endosteal surface of the bones. Higher levels resulted in more extreme bone changes and also a marked increase in serum calcium and serum lipids. Extreme lipemia occurred at the highest levels of injection.

Factors concerned in the duration of pregnancy, F. F. SNYDER (*Physiol. Rev.*, 18 (1938), No. 4, pp. 578-596).—A review is presented of the hormonal and other factors inhibiting and inducing parturition, changes in the uterus during parturition, prolongation of pregnancy by prolongation of the activity of lutein tissue, and the role of the ovarian, pituitary, and placental hormones in the control of pregnancy in the ovarian cycle.

FIELD CROPS

Measuring crop yields on a community scale, F. S. REYNOLDS and A. E. COLDWELL (*Jour. Amer. Soc. Agron.*, 30 (1938), No. 8, pp. 635-643).—In a rapid method developed for measuring yields of grain sorghum, fields are divided into equal strips and yields are taken in sample areas spaced every 25 rows or equivalent distances through the center of the strips, and sorghum heads are counted and part weighed for estimation of yield on an acre basis. Yields so calculated were generally accurate to within 10 percent. On fields from 80 to 640 acres, one sample should represent not more than from 3 to 5 acres. One man can measure the yield on from 300 to 500 acres of grain sorghums a day. The method may be useful in evaluating such farm practices as furrowing, ridging, contouring, and terracing on ranch and farm lands.

[Field crops research in Hawaii], J. E. WELCH, SUMIDA, W. W. JONES, G. K. PARRIS, J. H. BEAUMONT, M. TAKAHASHI, J. C. RIPPETON, E. K. AKAMINE, E. Y. HOSAKA, and [L. D.] WHITNEY (*Hawaii Sta. Rpt. 1938*, pp. 22, 24-27, 55-62, figs. 3).—Further experimentation (E. S. R., 79, p. 469) with field crops, reported on briefly, including breeding, variety, cultural, storage, and spindling-sprout studies with potatoes; variety, spacing, and baking tests with sweet-potatoes; cutting and strain tests with Napier grass; germination, viability, and storage tests with crop seeds; a vegetational survey of pasture areas; and adaptation studies with grasses and clovers.

[Field crops research in Idaho, 1938]. (Partly coop. U. S. D. A.). (*Idaho Sta. Bul.* 229 (1939), pp. 15, 16, 17, 18, 35, 36, 37, 39-44).—Brief reports of progress are again (E. S. R., 80, p. 36) made from experimentation at the station and substations, including breeding work with winter and spring wheat, oats, and *Phalaris tuberosa*; variety tests with winter and spring wheat, oats, barley, forage grasses, and pasture mixtures; modification of sprouting of potatoes by chemical treatments; effects of nurse crops with clover and alfalfa; effects of row spacing on seed yields of grasses and seed production tests; fertilizer trials with alfalfa, corn, barley, wheat, crested wheatgrass, and pasture; and control of bindweed by cultivation, competitive cropping, and sodium chlorate. New varieties released as results of breeding work included Idaed white spring wheat (the result of Sunset × Boadicea made by V. H. Florell), Lemhi (Federation × Dicklow) wheat, and Bannock (Markton × Victory) oats, and a perennial grass developed from Mosida winter wheat × native ryegrass (*Elymus condensatus*).

[Crop research in Indiana], J. T. SULLIVAN, H. R. KRAYBILL, C. B. GUSTAFSON, G. P. WALKER, R. R. MULVEY, G. H. CUTLER, S. R. MILES, H. L. COOK, W. W. WOZELLA, C. E. SKIVER, R. M. CALDWELL, L. E. COMPTON, and A. T. WIANKO (*Indiana Sta. Rpt. 1938*, pp. 11, 12, 28, 29, 30-33, 42, 88, 89, 90, 91, 92, figs. 3).—Brief reports of progress are made from agronomic work (E. S. R., 79, p. 617) concerned with effects of fertilizer applications and other practices on kernel characteristics of winter wheat; manurial value of crop residues on Clermont silt loam; the effect of lime on inoculation and yield of soybeans on Alford silt loam; effects of side dressing corn with nitrogen; merits of the Richland soybean; corn varieties and hybrids for different soils; hilling v. drilling of fertilized corn; formaldehyde v. ethyl mercury phosphate seed treatments on oats yields; use of cyanamide for weed control; study of 11 characters of 30 varieties of soft and semihard wheat; technic for determining the fineness of wheat meal or granulation; wheat improvement in southwestern Indiana; inheritance of a lethal seedling character in common and durum wheat; soil fertility studies involving response of corn, wheat, soybeans, and clover in rota-

tions to fertilizers, lime, and manure; a comparison of clover, alfalfa, sweetclover, Korean lespedeza, and timothy in rotations with corn and wheat; an experiment with a 4-yr. rotation of corn, corn, soybeans, and potatoes to determine the need in well-disintegrated deep muck of the nonacid type for lime, phosphorus, and potassium; and an experiment on Crosby silty clay loam in a 3-yr. rotation of corn, wheat, and mixed hay to determine effects of lime, manure, and commercial fertilizers, and combinations of these upon soil fertility.

[Agronomic work by the Fruit and Truck Station] (*Louisiana Sta., Fruit and Truck Sta. Bien. Rpt. 1937-38, pp. 12, 13, 15-17, 19, 21*).—Variety tests with potatoes, winter legumes, and sugarcane; fertilizer and liming studies with potatoes, sweetpotatoes, lespedeza, and hairy vetch; plant production tests with sweetpotatoes; and inoculation studies with hairy vetch and soybeans are reviewed in brief progress reports. Pasture Improvement in the Florida Parishes, by R. H. Lush (p. 21), reports the response of different pasture clovers and grasses to different fertilizer treatments.

[Crops experiments at the North Louisiana Substation], S. STEWART and N. D. MORGAN (*Louisiana Sta., North Louisiana Sta. Bien. Rpt. 1937-38, pp. 5-22, 25-28*).—Average results are reported from experiments during varying periods with field crops at Calhoun (E. S. R., 77, p. 181), including variety tests with cotton, corn, cowpeas, soybeans, crotalaria, sugarcane for sirup, grain sorghum, potatoes, and sweetpotatoes; breeding work with cotton; fertilizer trials with cotton, corn, potatoes, and sweetpotatoes; seedbed preparation and planting tests with cotton and corn; spacing tests with corn and sweetpotatoes; comparisons of winter cover crops for cotton, corn, and sorghum for silage; effects of grazing by dairy cattle on production of different varieties of sweetpotatoes; a manured and fertilized rotation; a production test with alfalfa; and a trial of cornstalks and sugarcane bagasse as heating material for sweetpotato hotbeds.

[Experiments with rice and other crops in Louisiana, 1937-38], J. M. JENKINS. (Coop. U. S. D. A.). (*Louisiana Sta., Rice Sta. Bien. Rpt. 1937-38, pp. 4-17*).—Rice investigations (E. S. R., 77, p. 473), reported on briefly for 1937 and 1938, included variety, date of seeding with grain drill and in water, date and manner of submergence tests, rice rotations, fertilizer trials, and studies of the effect of holding water on rice lands in alternate years when not sown to rice. Progress in Improving Rice Varieties, a special article by N. E. Jodon (pp. 15-17), reviews breeding work. Experiments with other crops included variety tests with cotton, soybeans, grain sorghums, and sorgo; fertilizer tests with cotton; date of planting tests with corn, grain sorghums, and sorgo; different row widths for corn and cotton; a cotton and corn rotation; and a permanent pasture experiment.

[Field crops experiments in Nebraska]. (Partly coop. U. S. D. A.). (*Nebraska Sta. Rpt. [1938], pp. 19-30, 31, 32, 47, 48, 50, 51, 52, 53*).—Research with field crops (E. S. R., 79, p. 472) reported on from the station and substations included variety tests with winter and spring wheat, corn, oats, barley, grain sorghums, sorgo, alfalfa, sweetclover, soybeans, and Jerusalem-artichokes; breeding work with corn (and hybrids), sorghum, wheat, oats, barley, alfalfa, sweetclover, and potatoes; inheritance of green cotyledon color and dwarf branching habit in sweetclover; crop rotations; response of wheat, sorghum, and spring grains to fallow and other tillage practices; effects of manure and alfalfa on sugar beets and potatoes in rotations; storage and nutrition studies with potatoes; drying seed corn with heated air under forced draft; planting tests with corn, sorghum, and sugar beets; response of sorghum to length of day; cold resistance tests with strains of Argentine alfalfa; study of seed setting

in alfalfa; a clipping test and coumarin determination with sweetclover; surface v. furrow drilling of wheat, oats, and barley; plowing v. disking cornstalk land for oats and barley; production of foundation stocks of seed potatoes; growing crops with pump irrigation; pasturing of winter wheat at different degrees of severity; improvement of permanent pastures and meadows by improvement of species for reseeding; tests of forage species; response of grasses to intensity of clipping; a range survey in a sand hill area; and control of bindweed by cultivation and sodium chlorate.

Soil-conserving and soil-improving crop rotations for the Palouse, S. L. SLOAN, A. W. JACKLIN, and V. G. KAISER. (U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 4, pp. 300-313, figs. 9).—The problem of the introduction and establishment of soil-conserving and soil-improving crop rotations in the Palouse of eastern Washington and adjacent Idaho is discussed from findings on the demonstration project on the South Fork of the Palouse River. Two 6-yr. and one 4-yr. soil-improving rotations, planned for croplands having gently sloping and only moderately eroded soils, are designed to improve the physical condition of the soil and to increase or maintain the fertility and productiveness. Two 6-yr., one 7-yr., and one 9-yr. soil-conserving rotations, planned for use on the most severely eroded croplands and on the steeper slopes, provide an erosion-controlling cover on the land a major portion of the years in every cycle, improve the productivity and physical condition of the soil, and also provide protective vegetative cover.

Grasses of the Hawaiian ranges, L. D. WHITNEY, H. Y. HOSAKA and J. C. RIPPETON (*Hawaii Sta. Bul.* 82 (1939), pp. 148, figs. 81).—The technical and popular descriptions of 103 of the most important grasses in Hawaii, presented with illustrations, show the characteristics, origin, value in native land, occurrence in Hawaii, nature of growth, and value on the range. Very few of the native species are common on the range, the introduced species being far more important in point of number and of forage value. Appropriate keys to the tribes and genera are included, together with a list giving botanical and common names, native countries and dates of introduction of species, a glossary, and an index.

Susceptibility of seedling grasses to damage by grasshoppers, W. HERMANN and R. ESCHKE. (Wash. Expt. Stn.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 4, pp. 333-337).—Species of grasses varied significantly in 1938 in susceptibility to grasshopper attacks of four grasshoppers at Pullman, Wash. *Bromus mollis*, *Deschampsia elongata*, *Festuca idahoensis*, *F. ovina*, and *F. rubra* var. *commutata* displayed complete defoliation. *Agropyron cristatum*, *A. elongatum*, *A. repens*, *A. subsecundum*, *Arrhenatherum elatius*, *Dactylis glomerata*, *Elymus glaucus*, *F. elatior*, *Hordeum bulbosum*, and *Poa secunda* showed an average of between 80 and 100 percent defoliation by grasshoppers. *Agropyron smithii*, *B. inermis*, *E. canadensis*, and *Phalaris arundinacea* suffered an average damage of less than 20 percent for each species. Other species were intermediate in susceptibility to grasshopper damage. Among species, growth habit, i. e., winter—entirely vegetative, or spring—first-year flowering, had slight influence upon respective susceptibilities, but within a species selections with winter habit of growth showed a greater susceptibility toward grasshopper damage than those with spring habit. Selections within each species differed widely in comparative susceptibility to damage by grasshoppers. The extreme differences observed between seedling grasses in resistance to attacks by grasshoppers may indicate a greater ease of establishment of some species of grass than of others in areas where the insects are numerous enough to do considerable damage without completely destroying the plants.

A short bibliography on grasses, grasslands, and fodders in India (*Agr. and Livestock in India*, 9 (1939), No. 3, pp. 290-300).—The list includes 190 references.

Perfect-flowered buffalo grass (*Buchloe dactyloides*), R. L. HENSEL. (Tex. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 30 (1938), No. 12, pp. 1043, 1044, figs. 2).—Plants were found which produced perfect flowers on what was normally the staminate inflorescence. Several matured florets from these plants produced apparently fully developed caryopses, though much smaller than normal seed produced by the female plant. The pollen was demonstrated to be functional by normal seeds obtained from crosses in which the perfect-flowered plant served as the pollen parent.

Some factors affecting the prevalence of white clover in grassland, B. A. BROWN. ([Conn.] Storrs Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 4, pp. 322-332).—Over 3 yr., strains of clover indigenous in old pastures of England, New Zealand, and the United States have maintained the best stands in grass-clover seedings, while Polish, Danish, and commercial white Dutch were the shortest lived. As to longevity, little choice appeared between seed from northern, southern, or far western parts of the United States. Climatic conditions were less important than fertilization or species of grasses in maintaining white clover in mixed stands. Clover was much less prevalent with turf-forming grasses, as bluegrasses and bents, than with species having more open stands.

Retarding effects of nitrogenous fertilizers on clover in grassland were due chiefly to increased grass competition caused by nitrogen. In grazed permanent pastures, very little clover has been present without addition of phosphorus. Pastures with complete minerals (PLK) had the most clover, but omission of K had little effect. On an adjacent permanent meadow mowed in June for hay and grazed in late summer and fall, either potassium or manure added with superphosphate and limestone was very effective in promoting large amounts of clover. On Charlton fine sandy loam soil, minor elements have had no appreciable effects on clover. Lawnmowing to $\frac{1}{2}$ in. (v. 1 in.) for one season greatly decreased both Ladino and Kent clovers in Kentucky bluegrass-clover seedings, but Kent clover increased slightly under this management in mixture with less bluegrass. Amounts of volunteer white clover increased with height when vegetation was mowed during 4 yr. under different methods of fertilizing Kentucky bluegrass and Rhode Island bentgrasses cut when 2, 3, 4, and 5 in. high.

Tests of corn varieties and hybrids in Utah, R. W. WOODWARD, D. C. TINGEY, and R. J. EVANS. (Coop. U. S. D. A.). (*Utah Sta. Bul.* 287 (1939), pp. 32).—Variety tests in different localities in the State with corn for grain, 1931-36, and silage, 1934-38, suggest for sections with an average growing season U. S. Hybrid 52 (Ohio Hybrid O72), with a long growing season Reid Yellow dent, and for sections with short seasons (95-105 days) Will Allen, Canadian flint, or certain early strains of Minnesota 13. Ohio Hybrid W63 also was found superior in yield to standard varieties for the main agricultural areas of the State. Wide variations in yield and other agronomic characters were observed among strains of Minnesota 13 and its derivative Colorado 12. See also a previous note (*El. S. R.*, 61, p. 633).

Effect of nitrogen, phosphorus, and potassium in fertilizers on the earliness of cotton, H. B. BROWN and H. W. POPE (*Louisiana Sta. Bul.* 306 (1939), pp. 15, figs. 11).—The effect of each of three nutrient elements on earliness of cotton was studied, 1927-31, in connection with fertilizer tests noted earlier (*El. S. R.*, 80, p. 595).

Cotton receiving heavy applications of phosphorus produced higher percentages of seed cotton at first picking, had a higher blooming rate in the first 2 weeks of the blooming period, and resulted in higher yields of seed cotton than cotton receiving no phosphorus (NK) or no fertilizer. Plats heavily fertilized with nitrogen did not differ much from no nitrogen (PK) or no fertilizer plats in earliness or rate of blooming, but were consistently higher in yield. Potassium seemed to retard boll opening as compared with no potassium (NP) or no fertilizer, was similar in blooming rate, and greatly outyielded these plats in order.

When the three elements were heavily applied respectively in complete fertilizers, cotton receiving the heavy application of phosphorus was outstanding in blooming rate during the first 4 weeks and very little behind in the fifth week. Plats receiving heavy applications of nitrogen or potassium, not significantly different from each other, were intermediate between the unfertilized and the heavy phosphorus plats in blooming rate. Over the period, fertilized plats showed an upward trend without differing greatly, although cotton receiving heavy potassium treatment seemed outstanding in 3 of 5 yr. Unfertilized plats showed a downward trend in yield. A heavy rate of blooming as indicated by the phosphorus curve did not necessarily mean high yields.

Relation of the structure of the chalazal portion of the cotton seed coat to rupture during ginning, N. L. PEARSON. (U. S. D. A. and S. C. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 58 (1939), No. 11, pp. 865-873, pls. 3, figs. 2).—Material representing different stages in the development of the seeds of Super Seven and Acala (*Gossypium hirsutum*) and Pima (*G. barbadense*) cottons showed that the chalazal part of the seed coat has a very characteristic structure. The palisade layer ends at the point of attachment of the inner integument to the chalaza, and thus a small opening, left in the palisade layer, is nearly filled with a fairly compact mass of undifferentiated cells, the chalazal plug. The inner and especially the outer pigment layers are thicker in the chalazal region than elsewhere on the seed and are spongy in nature. In chalazal chipping, the main rupture occurs in the spongy tissue—either above or below the vascular strands. The broken areas vary in size in different seeds but usually include a part of the spongy tissue very close to or over the chalazal plug. This outer spongy tissue constitutes a weak place in the seed coat, and its existence furnishes one explanation for the chipping of cotton seeds at the chalazal end during ginning, which adds undesirable foreign matter to the ginned lint.

Limesone mobilizes phosphates into Korean lespedeza, W. A. ALBRECHT and A. W. KLEMME. (Mo. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 4, pp. 284-286, fig. 1).—Korean lespedeza grown on Putnam silt loam in 1938 responded to phosphates alone and especially with limestone in increased crop and nitrogen harvest. The use of these materials together also served to mobilize the phosphorus into the crop more effectively for an increase in the total crop harvest and in its relative content of protein.

Potato culture and storage investigations in 1937 and 1938, E. V. HARDENBURG. (Cornell Univ.). (*Amer. Potato Jour.*, 16 (1939), No. 6, pp. 143-150).—Recent research on potato culture and storage is reviewed, with a list of 42 references.

Soybeans: Their effect on soil productivity, O. H. SEARS (*Illinois Sta. Bul.* 456 (1939), pp. 545-571, figs. 10).—Soybeans, whether used for hay to be fed on the farm or sold, for grain to be sold and straw returned to the land, or for green manure, are discussed as to their effects on soil tilth and tendency toward erosion, on activity of soil bacteria, on plant-food balance, and on other crops in the rotation. Conclusions from the report, which is based largely on

experiments at this and other experiment stations, may be summarized as follows:

Soybeans, to fit most usefully into Illinois cropping systems, must be handled so as to contribute to soil conservation and not to soil depletion. Best control of erosion where soybeans are grown on rolling land is secured by drilling solid and following with a winter cover of drilled small grain, both crops on the contour. Where soybeans are drilled solid up and down the slope, erosion losses usually are reduced about half. As many weeds as possible should be killed before and shortly after seeding. Introduction of a high-yielding, early-maturing soybean which can be harvested early enough for wheat to be sown afterward at the normal time is a desirable objective.

Part of the soybean tops must be returned in some form to the soil or nitrogen will be depleted. Combining the beans and leaving the straw on the land may result in a slight increase in soil nitrogen if it is not leached before used by the next crop. As green manure soybeans supply organic matter containing from 60 to 100 lb. of nitrogen an acre, but the relatively high cost usually is a drawback to this practice. Soybeans should be considered primarily as a cash or feed crop, and other legumes, such as sweetclover, red clover, and alfalfa, used for soil improvement. Since on many less fertile soils soybeans can use nutrient elements not available to many other crops, these mineral elements should be returned by fertilization to maintain soil productivity at a satisfactory level. Where winter grain is sown on rolling land on the contour after soybeans are harvested, as indicated above, on most soils a phosphatic fertilizer should be applied. On land not subject to serious erosion, the spring-planted oats and corn generally do better after soybeans than do fall-sown crops without fertilizer.

Soybean production in Kansas, J. W. ZAHNLEY (*Kansas Sta. Bul.* 282 (1939), pp. 28, figs. 7).—A revision of Bulletin 249 (E. S. R., 63, p. 441) is presented. Varieties currently regarded as desirable on the basis of station tests, 1930-37, are Hongkong, A. K., and Selection 6 (from A. K.) for general use for seed and also good hay producers, and Pinpu, Manchu, and Illini where an earlier variety is wanted. Laredo is regarded as the leading hay variety for Kansas. Hongkong, A. K., and Laredo led in average seed yields in tests in southeastern Kansas, 1924-27, and Laredo was first in hay production.

Growing sweetpotatoes in the Yazoo-Mississippi Delta, E. A. CUREY (*Mississippi Sta. Bul.* 327 (1939), pp. 14, figs. 5).—Practical suggestions derived from extensive studies of fertilizers, varieties, and curing and storage at the Delta Substation include the choice of a light, well-drained, sandy loam or loam with clay subsoil; fertilization with from 125 to 250 lb. per acre of a nitrogen carrier providing from 20 to 40 lb. of nitrogen per acre applied under the rows at bedding and preferably 2 weeks or longer before setting plants; the Porto Rico variety; use of about 8 bu. of seed roots in a manure- or flue-heated hotbed to provide plants enough for an acre; planting on beds in rows 36 in. wide and plants 12 in. apart; cultivating enough to keep the soil free from grass and weeds; and careful harvesting and handling and field grading. The sweetpotatoes should be placed in a curing house within a few hours after digging and kept for 10 days at from 80° to 85° F. and relative humidity of 90 percent. The temperature should then be reduced gradually and maintained at about 55° throughout storage.

The information, except for fertilizers, also applies to other parts of Mississippi. For the hill sections the station recommends the use of from 500 to 1,000 lb. per acre of 4-8-4, 6-8-4, or 6-8-8 fertilizer, according to the fertility needs of the different soils.

Growing wheat in the eastern United States, S. C. SALMON and J. W. TAYLOR (*U. S. Dept. Agr., Farmers' Bul. 1817 (1939), pp. [2]+59, figs. 52*).—Wheat varieties and their distribution and adaptations, cultural and field methods, and harvesting and threshing practices are described, and information is given on the status of the crop, its climatic and soil needs, and control of diseases and insects. Weed control is described in *Weeds in Wheat*, by L. W. Kephart (pp. 54, 55). This publication is a revision of and supersedes *Farmers' Bulletins* 596 (*E. S. R.*, 31, p. 438), 616 (*E. S. R.*, 32, p. 336), 885 (*E. S. R.*, 38, p. 240), 1168 (*E. S. R.*, 45, p. 133), and 1305 (*E. S. R.*, 48, p. 835).

Commercial agricultural seeds, 1938, G. P. STEINBAUER (*Maine Sta. Off. Insp. 170 (1938), pp. 91-119*).—The purity, germination, hard seed content (in legume seed), and noxious weeds, where present, are tabulated for 190 samples of agricultural seed collected from dealers in Maine in 1938.

The soil moisture relationship of European bindweed growing in corn, A. L. BAKKE. (Iowa Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 4, pp. 352-357, figs. 3).—Soil samples taken at 1- and 2-ft. depths from cornland heavily infested with bindweed and from soil free of the weed during the summer months of 1933, 1934, and 1935 did not differ markedly in soil moisture content. Bindweed could maintain itself when the moisture content was below the wilting coefficient, probably due to the deeply penetrating root system, but corn did not compete successfully near the wilting coefficient. Corn grown in 1933 on a heavily infested area kept free of bindweed by weekly hoeing produced twice as many pounds of corn as a control area receiving three cultivations.

Dodder control in annual lespedezas, R. E. STITT. (U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 4, pp. 338-343).—The life history of field dodder (*Cuscuta pentagona*) on annual lespedeza is given in brief, with a list of crops and weeds observed as host plants and accounts of seed cleaning and control experiments.

Germination under field conditions occurs throughout the growing season. Growth is rapid and blossoms were found 21 days after attachment to the host. Seed of field dodder could not be removed entirely from annual lespedeza seed by screens. Dodder growing in the field could be destroyed by several methods, e. g., burned with a blowtorch, cut out by hand, or sprayed with chemicals. The most economical will depend on labor and material costs. Effective chemicals tested included a 2.5-percent solution by weight of sulfuric acid with water, ammonium thiocyanate 1 lb. in 2 gal. of water, and "Atlacide" 1½ lbs. in 1 gal. of water, all of which killed all plants of both dodder and lespedeza when thoroughly moistened by spraying. Spraying with chemicals does not prevent production of dodder seed if seed balls have begun to form.

HORTICULTURE

[Horticultural studies by the Hawaii Station], W. B. STOREY, W. W. JONES, M. E. HARTUNG, J. H. BEAUMONT, [B. J.] COOIL, P. GUEST, [H.] KUBOTA, J. E. WELCH, SUMIDA, L. A. DEAN, and R. YOSHIDA (*Hawaii Sta. Rpt. 1938, pp. 11-22, 23, 27-30, 45-47, 54, 55, figs. 3*).—Included are brief progress reports on the following studies: Genetics, breeding and selection, and sterilization and storage of papaya; morphology, breeding, culture, growth habits, oil storage, and chlorosis of the macadamia nut; culture and pruning of coffee; composition and storage of the mango; growing of truck crops; composition of coffee trees as affected by fertilization; quality in coffee; and breeding and selection of sweet corn.

[Horticultural studies by the Indiana Station], O. W. FOED, D. M. DOTY, J. R. ROACH, C. E. BAKER, J. A. MCCLINTOCK, C. L. BURKHOLDER, T. E. HENTON,

H. C. STAIR, J. D. HARTMAN, F. C. GAYLORD, K. I. FAWCETT, E. R. HONEYWELL, J. E. DICKERSON, N. K. ELLIS, and J. P. BIEBEL (Partly coop. U. S. D. A.). (*Indiana Sta. Rpt. 1938, pp. 10, 12, 70-74, 75-79, figs. 4*).—Among studies the progress of which is discussed are spray residue removal, inbreeding of sweet corn, orchard soil management and cover crops, apple propagation and spraying, varieties of peaches and plums, storage of apples, production of tomato seed, fertilizer and cultural studies with the tomato, the marketing of fruits and vegetables, grading and marketing of peonies, quality of canned tomatoes, production of muck and sandy soil crops, use of supplemental light in the greenhouse, and the growing of pyrethrum for insecticidal purposes.

[Horticultural studies by the Fruit and Truck Experiment Station], W. F. WILSON, JR., J. C. MILLER, and W. D. KIMBROUGH (*Louisiana Sta., Fruit and Truck Sta. Bien. Rpt. 1937-38, pp. 1-12, 14, 15, 18, 19, 20*).—Included are reports on the results of studies on the fertilizer and cultural requirements of the strawberry; yield of fruit from plants produced at different times; effect of lime on strawberry yields and plant production; mulching of the strawberry; effect of source of plants; fertilizer and lime requirements of the pepper, bean, cucumber, and cabbage; growing of tung trees, mayhaws, and velvet; fertilizer for the Satsuma orange; improvement of the blueberry; and variety tests of grapes, pecans, and various bush fruits.

[Horticultural studies by the North Louisiana Substation], N. D. MORGAN (*Louisiana Sta., North Louisiana Sta. Bien. Rpt. 1937-38, pp. 22-25, 28, 29*).—Brief reports are offered on variety and fertilizer tests with tomatoes and watermelons and varieties of peaches, apples, and pecans.

[Horticultural studies by the Nebraska Station] (*Nebraska Sta. Rpt. [1938], pp. 30, 49*).—Contained are progress reports on the following studies: Cultural requirements of orchard trees and grapevines; irrigation of orchards; and yield tests of sweet corn, tomatoes, and onions.

Effect of storage, bulb size, spacing, and time of planting on production of onion seed, H. A. JONES and S. L. EMSWELLER (*California Sta. Bul. 628 (1939), pp. 14, figs. 2*).—Using a strain of Ebenezer onion known to have produced poor crops of seed in some years, mother bulbs were placed, after harvest, in six storage conditions, namely 38.5°, 46.5°, 53.5°, and 86° F. constant temperatures, in a basement room at from 61° to 71.5°, and in a warehouse where the temperature and relative humidity fluctuated with the weather. In early December the bulbs were removed and set in the field. Plants from bulbs stored at 46.5° and 53.5° were always first to bloom and to mature seed. The 86° bulbs were latest to bloom and mature seed. Bulbs held at 53.5° produced the largest number and those at 86° the smallest number of seed heads. The mean yield of seed was highest from the 53.5° plats, but was not significantly above the 46.5° plats. The 86° bulbs produced the least seed. Both high and low storage temperatures depressed seed yields.

Later studies with a free-seeding strain of Ebenezer, Yellow Globe Danvers, and a strain thereof showed comparable results, although the several varieties did not respond in the same manner to the different storage conditions. In a comparison of eight sizes of mother bulbs of Yellow Globe Danvers ranging in weight from 15 to 90 gm., there was observed an increase in the number of seed heads per plant, seed yield per plant, and seed yield per acre as bulb size increased. In the case of Yellow Globe Danvers bulbs set 3, 4, 6, 8, and 12 in. apart in the row, a significant increase in seed yield per plant followed each increment, but the total yield per acre was decreased. With Yellow Globe Danvers bulbs set in the field at different dates from December 7 to March 2, there was, in general, a decrease in seed yield as the planting was delayed. Late setting caused late blooming and greater opportunity for thrips injury.

Classification of tomato varieties according to physiological response, V. A. TREDJENS and L. G. SCHERMERHORN. (N. J. Expt. Stas.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), pp. 737-739).—Pritchard, Bonny Best, Globe, Marglobe, and Rutgers tomato plants grown at six different root temperatures—55°, 60°, 65° 70°, 80°, and 90° F.—with air temperatures approximately 58° at night and 78° during the day made their best growth in the range between 65° and 80°. Varieties with a high rate of metabolism, such as Rutgers, made the greatest response to low temperatures and were most adversely affected by high temperatures. When root temperature was high enough to inhibit fruit set in Rutgers, the starch present in the afternoon disappeared completely during the night and was absent from the pollen grains. In contrast, pollen grains of plants that set freely always gave a positive reaction for starch. Suggestions as to the differential fertilizer requirements of various varieties are presented.

Experiments on tomato plants and planting methods, Pennsylvania State College, 1938, W. B. MACK (*Canning Age*, 20 (1939), No. 6, pp. 243, 244).—Based on the yields of randomized, replicated plots, no significant differences were found except in one case (which could be explained by the condition of the plants at time of setting) in total yield of Rutgers tomato plants secured from 16 different sources including the Southern States. With respect to early yield during the first 3 weeks, two lots, one from a certified southern source and one cold-frame spotted source, were definitely superior and three were definitely lower. In a study of the effect of nutrients applied to Rutgers plants at the time of setting, no treatment was significantly better than water alone with respect to total yields, but two P treatments did increase early yields significantly.

Some effects of potassium and nitrogen on the composition of the tomato plant, T. G. PHILLIPS, T. O. SMITH, and J. R. HEPLER (*New Hampshire Sta. Tech. Bul.* 73 (1939), pp. 11).—Observations on the chemical composition of Sunrise tomato plants grown in sand, with and without external supplies of K and on different N levels, showed, at the point where K deficiency became evident, certain well-defined effects of the variation in the N supply on K assimilation. In plants grown with very high N, the ash in percentage of dry weight was uniformly lower in the plants without K than in those with K. At the lower level of N supply, the percentage of K in the ash was increased. At the high N levels a lack of K was decidedly depressing on growth, whereas at a very low N level K deficiency actually improved growth slightly. At a low N level, starch was more abundant in the stems of the -K than in the +K plants. No striking evidence was found for K deficiency to produce abnormalities in N metabolism. The results supported the hypothesis that a balance between K and N is important in the growth of plants.

The fundamentals of fruit production, V. R. GARDNER, F. C. BEADFORD, and H. D. HOOKER, JR. (*New York and London: McGraw-Hill Book Co.*, 1939, 2. ed., pp. XVI+788, pls. 3, figs. 76).—This is the second and revised edition (E. S. R., 47, p. 237).

Pollen longevity studies with deciduous fruits, J. R. KING and C. O. HESSE (Univ. Calif. and U. S. D. A.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), pp. 310-313).—In studies with varieties in the genera *Prunus*, *Pyrus*, *Cydonia*, and *Pistachia*, it was found that air-dried pollen, stored in vials and placed in sealed fruit jars, could be kept alive for at least 550 days under favorable conditions. In general, the optimum storage for most of the pollens tested was about 36° F. and 25 percent relative humidity. Pollens stored at 10° reacted very similarly to those stored at 0 percent relative humidity within the favorable temperature range.

Cytological and morphological features associated with impotency of pollen of the Winesap apple, J. N. MARTIN. (Iowa State Col.). (*Iowa State Col. Jour. Sci.*, 12 (1938), No. 3, pp. 397-404, pl. 1).—Pollen abortion in the Winesap apple is believed to be associated with abnormal development of tapetal tissue and pollen-sac wall cells. Tapetal tissue, instead of diminishing, continues its development to the extent that it crowds in upon the pollen and, in extreme cases, practically fills the locule, leaving little room for pollen development. In such cases, the pollen shows evidence of abortion in lack of density and a vacuolated condition of the protoplasm and ultimate shriveling and disorganization. Apparently, pollen abortion in the Winesap is the result of a reversal in physiological relationships in which the tapetal cells digest the pollen.

Incompatibility of Early McIntosh and Cortland apples, W. WEEKS and L. P. LATIMER. (Univ. N. H.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), pp. 284-286; also *New Hampshire Sta. Sci. Contrib.* 67 [1939], pp. 284-286).—Continuing these studies (E. S. R., 78, p. 49), the authors report that cross compatibility exists between McIntosh and its seedlings Melba, Milton, Cortland, Macoun, and Early McIntosh. However, in the Cortland \times Early McIntosh there was definite indication of cross incompatibility. Examination of the styles of Cortland \times Early McIntosh and vice versa showed no pollen tubes to have progressed more than one-fourth the way down the style. At the end of 24 hr., tubes ceased growth, and by the end of 48 hr. had swollen tips. In selfed Early McIntosh, tubes grew one-third the way down the style. On the other hand, in McIntosh \times Early McIntosh and Cortland \times McIntosh, pollen tubes grew steadily until the ovaries were reached. King, a triploid, proved of little or no value as a pollinizer for any of the McIntosh group.

An evaluation of ninety-six apple varieties at the 21-year period under Illinois conditions, R. L. McMUNN. (Univ. Ill.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), pp. 379-383).—Data are presented on the age of initial bearing, yields, susceptibility to fire blight, winter injury, etc.

Seasonal variation of oxygen and carbon dioxide in three different orchard soils during 1938 and its possible significance, D. BOYNTON and W. REUTHER. (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), pp. 1-6, figs. 2).—Of three subsoils—sandy loam, light silty clay loam, and silty clay—the atmospheres of which were studied from November 1937 to October 1938, only the sandy loam maintained high percentages of O₂ throughout both dormant and growing seasons at all depths down to 6 ft. In all three soils the percentage of O₂ decreased as the depth of sampling increased. In the silty clay it was impossible to obtain any gas samples between November 27 and June 14. Since the summer of 1938 was dry, it appeared likely that the differences in O₂ level were less and the duration of the period of aerobic conditions longer than would occur in normal or in wet seasons. In the heavier soils it was evident that the roots in the deeper levels were inactive during a considerable portion of the year.

Contour planting and terracing as a basis for soil and water conservation in orchards, J. T. BRIGGS. (U. S. D. A.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), pp. 7-18).—Tracing the history of contour planting of orchards, the author discusses types of orchard terraces, auxiliary erosion control practices (such as cover cropping and mulching), and effect of contour planting, and points out needed research. Four years' records obtained in a 25-percent slope vineyard at Hammondsport, N. Y., showed material increase in yield and decrease in water and soil losses on the countour plan as compared with up-and-down cultivation.

Phosphorus and potassium as supplements to nitrogen in sod mulch orchards in New Hampshire, G. F. POTTER and E. G. FISHER. (N. H. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), pp. 41-44; also *New Hampshire Sta. Sci. Contrib.* 69 [1939], pp. 41-44).—Comparisons in three orchards of different N fertilizers with commercial complete fertilizers applied in equal quantities with respect to the amount of actual N failed to show any response to the complete material which would justify its use. In one orchard, color was significantly better on the complete plats, but the yields were less. Growth of mulch was better in one case where the complete fertilizer was used.

Experimental production of winter injury to the trunks of apple trees by applying nitrogenous fertilizers in the autumn, M. A. TINGLEY, W. W. SMITH, T. G. PHILLIPS, and G. F. POTTER. (Univ. N. H.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), pp. 177-180; also *New Hampshire Sta. Sci. Contrib.* 71 [1939], pp. 177-180).—Of young Baldwin trees fertilized at four different dates during the autumn of 1936 with different N materials, only those treated on October 14 developed injury of the type described previously (E. S. R., 78, p. 49). Treatment of mature trees with cyanamide failed to result in any injury, although chemical analysis showed an appreciable increase in the total and soluble N contents in the roots, but none in the bark of the trunk or limbs. Mature McIntosh trees which had produced heavily in 1937 were fertilized that autumn with from 4 to 50 lb. of cyanamide or ammonium sulfate per tree. Despite the fact that neither artificial freezing, chemical analysis, nor the microscope revealed any change in the trunk tissue, it was observed in collecting January samples that the bark did not adhere to the wood in certain trees which had been fertilized with large amounts of ammonium sulfate. By February 3, a discoloration was noted in the region near the cambium which became progressively more evident. At the same time, trees receiving no fertilizer or smaller amounts of fertilizer were not affected. The indications were that available N applied in large amounts in autumn was concerned with the injury.

Anatomical studies of root and shoot primordia in 1-year apple roots, E. A. SIEGEL and J. J. BOWMAN. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 58 (1939), No. 11, pp. 795-803, pls. 11).—Observations were made on seedlings and named varieties in an attempt to relate vegetative responses with anatomical features. Limited experiments with clonal material indicate that successful propagation of apple root cuttings is dependent upon the ability of the cutting to push roots either in advance of, or concurrently with, shoots. Anatomical studies indicate that adventive shoot primordia are generally more completely organized than adventive root primordia. This condition probably accounts for the relatively quick emergence of shoots in certain clones before adequate roots are developed. Adventive primordia originate in tissues that have made considerable secondary growth. In general, root primordia are initiated in close association with the vascular cambium, and shoot primordia are organized as a result of activity of a small group of ray parenchyma cells near the periphery accompanied by divisions in the posterior regions.

The effect of a plant growth substance on croch angles in young apple trees, L. VERNER. (Idaho Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), pp. 415-422, figs. 2; abs. in *Idaho Sta. Bul.* 229 (1939), pp. 18, 19).—Working with yearling trees of Yellow Transparent, Delicious, and Jonathan apples, the author observed that injury, as by girdling, to the phloem immediately above a dormant bud invariably resulted in the development of a narrow-angled branch issuing from the bud. The assumption was that wide-angled crochets result from the action of a plant hormone formed in the growing tips of the

plant and passed downward through the phloem. When indolebutyric acid in lanolin paste was applied to the upper surface of the basal internode of a young shoot while the internode was still elongating, a marked increase was observed in the angle formed by the shoot and the trunk. After elongation had ceased and the tissues had hardened, neither girdling nor auxin treatment influenced the crotch angle. By permitting indolebutyric acid to diffuse slowly into the cut end of dormant whips that had been headed to about 30 in., it was possible to cause abnormally wide angles throughout the entire tree.

Apple thinning.—I, An analysis of bloom; II, The relation of thinning to size and the off year, M. J. DORSEY. (Univ. Ill.). (*Ill. State Hort. Soc. Trans.*, 72 (1938), pp. 410-415, 472-478).—Apple varieties differ with respect to the age of initiating fruit bearing, time of bloom, and manner of bearing. Hence there is a need of different pruning and thinning treatments. Varieties that bloom early are much more subject to frost injury than to unfavorable pollination conditions. An average bloom, in which from one-third to one-half the spurs produce flowers, is more desirable than a heavy bloom because in the moderate-blooming trees there will be a considerable percentage of spurs free to develop fruit buds for the succeeding year. In any given season there was a fairly close relationship between the extent of bloom and total yield. There was a definite tendency for apple trees to produce an enormous excess of blooms.

Various causes, such as complete blossom kill by low temperature, defoliation by scab, and a series of heavy crops, are known to upset regular fruiting in apple trees. Thinning of fruit affects the size of individuals and may aid in maintaining regular bearing. Thinning may be employed to improve the immediate crop, to prevent young trees from overbearing and going into an alternate status, and to restore regular fruiting after alternate bearing has been established. Thinning should be timed to begin after the natural drops.

Relation of seeds to pre-harvest McIntosh drop, L. SOUTHWICK. (Mass. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), pp. 410-412).—There was noted a moderate but significant correlation between seed number and time of preharvest dropping in the McIntosh apple. Seed content varied widely among trees, probably as a result of variability in the effectiveness of pollination, but this did not seem to alter appreciably its association with the date of drop.

Farm storages for New England apples, C. I. GUNNESS, W. R. COLE, and O. C. ROBERTS (*Massachusetts Sta. Bul.* 360 (1939), pp. 32, figs. 16).—Devoted for the most part to providing general information on the design and structure of storage buildings, refrigeration equipment and operation, management of storage houses, physiology and handling of fruit, temperature and relative humidity control, etc., this bulletin presents certain research results. McIntosh apples held at 45° F. during the 10-day harvesting period, and for 5 days later, developed their maximum quality; but when fruit was to be kept later than January 1, it was necessary to place it immediately in 32° storage. Although a high relative humidity (about 85 percent) is desirable, experiments showed that lower relative humidity during harvesting and storing is not essentially harmful.

Temperature in relation to peach production in Illinois, R. L. McMUNN. (Univ. Ill.). (*Ill. State Hort. Soc. Trans.*, 72 (1938), pp. 221-234, fig. 1).—A study of data reported in journals, U. S. D. A. Weather Bureau records, etc., showed 11 winters in the 105 yr. covered in which severe tree injury and complete loss of crops had occurred over the entire peach-producing area of Illinois. There was no regular sequence of disastrous years. Injury to trees did not usually occur until the temperature reached -10° F. or lower, but sometimes took place at somewhat higher temperatures. Generally, there was some killing

of fruit buds when the temperature reached 0°, but it was found to occur at temperatures as high as 10°. There were 27 yr. in the northern part of Illinois and 21 yr. in the southern when the fruit buds were all killed. Considerable difference was found in bud survival in different varieties in a given season and in a single variety in different seasons. Losses due to spring freezes were greater in the northern than in the southern limits, suggesting the possibility that from the standpoint of present varieties the peach is grown too far north in Illinois.

Hardy peach varieties, M. J. DORSEY. (Univ. Ill.). (*Ill. State Hort. Soc. Trans.*, 72 (1938), pp. 371-375).—Rating the Elberta as only about medium in hardness of fruit bud and producing less full crops in southern Illinois than does South Haven, the author discusses several of the newer peaches with respect to hardness of fruit buds, time of ripening, color of flesh, and general desirability. There was some indication that differential bud hardness was more important in southern Illinois than further north.

Precooling rail shipments of Illinois peaches, with special reference to the use of ventilated packages, J. W. LLOYD (*Illinois Sta. Bul.* 455 (1939), pp. 509-544, figs. 16).—Studies involving four cars of Elbertas in 1935 and three cars of Elbertas and one of Red Birds in 1937 showed a more rapid reduction in the temperature of the fruit during the precooling treatment in ventilated than in standard packages. Temperature of the fruit at the time of initiating the precooling treatment had a marked influence on the rate of cooling, yet even under the cooler conditions prevailing the ventilated packages cooled more rapidly. Data presented in detail for each of the eight cars showed certain discrepancies which are explained on the basis of existing temperatures, adjustments in the precooling equipment, etc. The four cars under observation in 1937 were followed to their destinations in other States, with temperature readings made at certain points en route. In general, the differences in temperature between ventilated and standard packages in a single car became less as time progressed. There was some indication of less decay in the ventilated packages, although, on the whole, the fruit of both baskets arrived in good condition. The benefit of ventilation was shown chiefly in the firmer condition of the fruit due to its more rapid initial cooling. In conclusion, the author asserts that precooling appears worthy of adoption as a general practice for rail shipments of Illinois peaches. Ventilating packages equipped with ventilated liners are conceded worth while in both precooled and nonprecooled refrigerated cars.

Plum variety trials in central Washington, W. J. CLORE, E. L. OVERHOLSER, and L. B. WOORON. (Wash. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), pp. 334-338).—Among points considered are date of blooming and ripening and the characters of recommended and promising varieties.

[The effect of different spray materials, such as bordeaux mixture, hydrated lime, and calcium acetate, in reducing the cracking of sweet cherry fruits] (*Idaho Sta. Bul.* 229 (1939), p. 18).—A brief report is presented.

Response of Howard 17 strawberry to sodium salts, L. P. LATIMER. (Univ. N. H.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), pp. 449-454; also *New Hampshire Sta. Sci. Contrib.* 70 [1939], pp. 449-454).—Following the earlier report (*U. S. R.*, 70, p. 481), in which it was indicated that in some years nitrate of soda caused a marked reduction in yield of Howard 17 (Premier) strawberries, the experiment was repeated with greatly increased numbers of replicates. Chemicals were applied in late July or early August in such a way that each of the cations Na, Ca, and NH₄ was combined separately with NO₃, PO₄, and SO₄ anions. In every case where Na was used, the yields the next

spring were significantly less than in the control plats or where ammonium salts were used. A slightly reduced yield occurred as a result of calcium nitrate fertilization. The plants were noticeably stunted where Na salts were used. In a repetition of the experiment, yields were reduced wherever Na salts were used, but calcium nitrate did not depress yields. Measurements of the leaves showed a reduced leaf area and a shortened petiole where Na was applied.

In another trial in which fertilizers were applied in early May, Na salts produced markedly reduced yields, varying from 33 percent with calcium nitrate to 50 percent with ammonium sulfate. The adverse effect on the leaves is believed associated with overreactativeness since yields from the sodium acid phosphate plats did not differ significantly from the controls. Sodium sulfate caused a slight depression accompanied by decreased leaf area and shortened petioles. Apparently sodium salts were injurious to newly forming roots and are thus particularly harmful when applied in midsummer.

Some results of self-pollination of the highbush blueberry at Whitesbog, New Jersey, E. WHITE and J. H. CLARK. (N. J. Expt. Stas.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), pp. 305-309).—Under controlled conditions in the field it was found that although the percentage of total flowers to set fruits was much the same in self- as in cross-pollinations, the individual fruits were, in almost every case, smaller in the self-pollinations. The difference in size was sufficient, in many cases, to put the selfed berries in a less desirable commercial grade. Furthermore, the small berries resulting from selfing were often green at the time the larger, cross-pollinated berries were mature. In one or two crosses there was an indication of cross incompatibility.

Starch in the avocado tree, S. H. CAMERON and G. BORST. (Univ. Calif.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), pp. 255-258, figs. 2).—Using whole trees and branches from individual trees, the authors found that the smaller branches and, to a lesser degree, the smaller roots were more variable in starch content than were the larger units. Maximum starch in the tree as a whole occurred in midwinter and the minimum in late summer and early autumn. Starch storage was observed almost as promptly in the roots as in the branches, due, apparently, to the low-branching habit of the tree. On the other hand, starch declined somewhat more slowly in the roots. Starch content was much lower throughout the summer and autumn in a bearing than in a nonbearing tree. The results as a whole suggest that the periods of maximum and minimum starch content are not constant but fluctuate from season to season depending on environment, size of the crop, and time of harvest. At all times, readily detectable starch was found, particularly in the primary xylem. Roots contained relatively more starch at all times than did branches of similar diameter.

Coffee production practices in Puerto Rico [trans. title], J. GUISCARÉ ARIYLLAGA and L. A. GÓMEZ (*Puerto Rico Col. Sta. Bul.* 49 (1939), *Span. ed.*, pp. 41, figs. 8; *Eng. abs.*, pp. 40, 41).—Based on a study of 398 plantations representing all possible conditions of location, altitude, type of soil, size, and type of management, the results show a notable lack of modern methods, especially in plant selection, use of fertilizers, pruning, and control of insects and diseases. As a result, the yields per unit area differ greatly, and since profitable production depends so greatly on good yields, there is a recognized need for improved cultural practices.

A further report on water use by Coachella Valley date palms, A. F. PILLSBURY. (Calif. Citrus Expt. Sta.). (*Date Growers' Inst. Rpt.*, 15 (1938), pp. 17-19, fig. 1).—In continuation of this study (E. S. R., 80, p. 52), the author states that frequency of irrigation and amount of water required will vary with

the season and with the soil type and suggests that applications from 6 to 7 in. deep at minimum intervals in summer of 2 weeks are adequate for sandy soils. On finer soils, the interval may be somewhat longer with heavier applications. The use of a total of 9 ft. per year should be sufficient for all needs. Suggestions are given as to the timing and the amounts of applications.

Cold storage of date pollen, C. L. CRAWFORD. (U. S. D. A.). (*Date Growers' Inst. Rpt.*, 15 (1938), p. 20).—Based on 2 years' studies, the author reports that dry date pollen stored in stoppered bottles and held at about 8° F. may be kept in a viable condition from one season to the next.

The size of date fruit as affected by soil moisture, D. C. MOORE. (U. S. D. A.). (*Date Growers' Inst. Rpt.*, 15 (1938), pp. 3, 4).—A 3-yr. study of the response of the Hayany date to soil moisture showed that applications of irrigation water in amounts of 8, 15, or 20 acre-ft. per year did not prevent some of the soil to a depth of 6 ft. from having its moisture reduced to the permanent wilting percentage. Where sufficient water was applied to reduce the proportion of soil to reach this percentage, the increased water usually increased the number of leaves and the size of the fruits.

Maturation and storage studies with soft varieties of dates, R. H. HIGEMAN and J. G. SMITH. (Ariz. Expt. Sta.). (*Date Growers' Inst. Rpt.*, 15 (1938), pp. 14-17, fig. 1).—Comparing a short high-temperature treatment followed by cold storage with the present commercial methods of extended low-temperature processing, the authors report that, in general, high-heat treatments produced dates inferior to those processed at low temperatures. No significant differences were evident between high-heat treatments at 140° and 150° F. for periods of from 2 to 4 hr. High heat may be applied successfully to Halawi dates except when very dry and was moderately successful with Khadrawi dates if they were dry, but in only 1 of 5 yr. proved successful with either Hayany or Maktoom. Moisture-proof containers retarded the formation of sugar crust and sugar spot but accelerated darkening and loss in flavor. Picking of early ripening dates should be delayed until the translucent stage is reached.

Growth of lemon fruits in relation to moisture content of the soil, J. R. FURN and C. A. TAYLOR (U. S. Dept. Agr., Tech. Bul. 640 (1939), pp. 72, figs. 24).—Concerned primarily with the response of lemon trees to decreasing soil moisture under orchard conditions, experiments were set up on several soil types to establish the effects on the growth of lemon fruits of wetting various proportions of the soil in the root zone. The results indicated that under the usual summer conditions the trees may obtain adequate moisture from as little as 50 percent of their root systems, provided the average moisture content of the wetted soil is relatively high. Apparently, an increased rate of extraction compensates in part for the reduction in absorbing area. It was evident, however, that the total amount of water absorbed by a tree decreased progressively with decrease in available wetted area.

Depth of soil favorable to root development was a potent factor in tree size and fruit growth. In one orchard on variable soil, trees in soil 2 ft. deep wilted at the same time as much larger nearby trees in soil from 4 to 5 ft. deep. In variable soils, average moisture content in the principal root zone may not serve as a reliable guide for timing irrigation. Readings should be based on samples from the zone of greatest root concentration.

Studies indicated that the relative moisture deficit of the lemon trees may be determined fairly accurately from the apparent growth rate of the fruit from a 20-cc. volume to the yellowing stage. A few trees should be supplied ample water to serve as standards of comparison. If water is withheld until

the apparent growth ceases, the ultimate size of the fruit will be reduced and considerable leaves will be lost. Apparent growth rate is deemed most useful as a guide for adjusting the irrigation interval already in use, and should be used in connection with soil moisture readings.

Root composition and top development in large pecan trees headed to various degrees of severity in top working, C. L. SMITH, J. HAMILTON, C. J. B. THOR, and L. D. ROMBERG. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 58 (1939), No. 11, pp. 821-842, figs. 10).—Analyses of the roots of trees of an average diameter of about 12 in. and headed back in varying degrees of severity prior to top working showed certain well-defined differences in composition as compared with nonheaded control trees. Starch and N were the most variable of the constituents studied. Starch was relatively very low in the roots of all headed trees and showed little fluctuation following cutting as compared with the behavior of the controls. The total leaf area, practically inversely proportional to the degree of severity of the heading, was apparently inadequate to synthesize sufficient carbohydrate to support growth, heal the wounds, and leave any excess for storage. The concentration of N in the roots was about the same in the control as in the headed trees. Sugars in pecan roots were apparently not of storage nature but labile forms for conversion into more complex carbohydrates. As to wounds, their rate of healing was approximately proportional to the amount of leaf area per tree. Cuts above 4 in. in diameter were slow to heal, and their use also resulted in so great a loss of leaf area as to prevent the adequate food development for normal recovery.

A physiological study of the prefilling period of fruit development in the pecan, C. J. B. THOR and C. L. SMITH. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 58 (1939), No. 12, pp. 905-910, figs. 4).—Analyses of pecan nuts at frequent intervals after pollination showed that the development of the shell was completed during the prefilling period. The shell developed rapidly during August, showing complete hardening during the first 3 weeks of that month. This development was accompanied by a rapid increase in acid-hydrolyzable polysaccharides and dry matter and a decrease in total sugars. The shuck development also was completed during the prefilling period, except for an increase in ash content and slight changes in the total sugars and acid-hydrolyzable polysaccharides. The prefilling period extends from date of blossoming to the beginning of oil formation in the kernel.

Common native shrubs of Mississippi for landscape plantings, F. S. BARSON (*Mississippi Sta. Cir. 100* (1939), pp. 15).—Brief comments and descriptive notes are offered.

FORESTRY

[Forestry studies by the Indiana Station], R. C. BRUNDAGE, D. DENUYL, and J. C. KASE (*Indiana Sta. Rpt. 1938*, pp. 62-68, figs. 4).—Progress reports are presented on the following studies: Marketing basket veneer and various woodland products, the effect of woodland management on yield and returns from marketable products, the establishment of Asiatic chestnuts, the destruction of undesirable weed trees, the propagation of tree seedlings, the establishment of windbreaks, and the propagation of plants useful in wildlife propagation.

Ohio Forest News, [July 1939] (*Ohio Forest News [Ohio Sta.]*, No. 36 (1939), pp. 8, pl. 1, figs. 7).—This is devoted to the historical aspects, geology, tree flora, and development of the Scioto Trail State Forest.

Development of timber industry in Tennessee and United States, C. E. ALLEN, S. W. ATKINS, and F. M. FITZGERALD (*Tennessee Sta., Agr. Econ. and*

Rural Sociol. Dept. Monog. 92 (1939), pp. II+38, figs. 8).—In mimeographed form there are presented facts concerning the early history and present status of forestry in Tennessee. Among subjects considered are the geographic shifts of lumber and forest products in the United States, trends in lumber production in Tennessee, and relation of lumber production to consumption.

DISEASES OF PLANTS

Report of the 1939 annual meeting of the southern division of the American Phytopathological Society (*Phytopathology*, 29 (1939), No. 8, pp. 749-757).—Abstracts of the following papers are included: Leaf Blotch, a New [*Gibberia*-associated] Disease of Rice and Certain Native Plants in Louisiana, by T. C. Ryker; Further Studies on Control of Soil Rot of Sweet Potatoes, by L. H. Person; The Necessity of Rotation of Crops for the Control of Diseases of the Sweet Potato, by R. F. Poole; Seed and Soil Treatments for Combating Damping-Off of Tomatoes, Eggplants, and Peppers, by L. H. Person; The Possible Control of Root-Rot Fungi by Soil Treatment With Chemicals, by R. F. Poole; Difference in Susceptibility of Tomato Varieties to *Septoria* and *Macrosporium* Leaf Spots, by J. O. Andes; Control of *Cercospora* Leaf Spots of Peanut With Various Dusts and Sprays, by L. Shaw; Bordeaux Injury to Cucumbers, by A. G. Plakidas; Carbon Dioxide Evolution From Certain Soils in Relation to Black Root Rot of Flue-Cured Tobacco, by J. A. Pinckard and L. Bozovaitsky; An Internal Collar Rot on Cotton, by C. J. King and H. D. Barker; Root-Knot Nematodes on Cotton and Tomatoes in Tennessee, by C. D. Sherbakoff; Observations on the Root-Knot Nematode in the San Joaquin Valley of California, by C. E. Scott, M. A. Lindsay, and G. J. Harrison; Preliminary Report on Cotton Wilt-Nematode Experiments at Lumberton, North Carolina, by A. L. Taylor, H. D. Barker, and O. P. Owens; Benefits of Winter Green-Manure Crops in Controlling *Phymatotrichum* Root Rot of Cotton, by C. J. King and J. T. Presley; Relation of Variations in Rainfall in 1938 to Prevalence of Cotton Root Rot, and Girdling of Cotton Plants as Affecting Survival of *Phymatotrichum omnivorum*, both by W. N. Ezekiel; Attempts to Control *Verticillium* Wilt of Cotton and Breeding for Resistance, by B. A. Rudolph and G. J. Harrison; Permeability of the Testa of Normal and Treated Cotton Seeds, by J. G. Brown; Fungi Associated With Seedling Diseases and Boll Rots of Cotton in Eastern United States in 1938, by P. R. Miller; Factors Influencing the Distribution and Persistence of Angular Leaf Spot in Irrigated Cotton Fields, by C. J. King and R. B. Parker; Effect of Period and Type of Storage of Cotton Seed After Treatment With Organic Mercury Dusts, by L. E. Miles; Seed-Treatment Tests With Cotton in 1938, by D. C. Neal; Seedling Survival as Affected by Certain Mercury, Copper, and Zinc Preparations not Included in the Regional Cotton Seed Treatment Tests for 1938, by S. G. Lehman; Treatment of Cotton Seed With Organic Mercury Dust and Sulphuric Acid, by G. J. Harrison; Variability of *Fusarium vasinfectum* in Culture, by R. Weindling; Some Tests of Varietal Susceptibility to a Combination of Nematodes and Cotton Wilt, by L. E. Miles; Artificial Inoculation With the Cotton-Wilt Fungus, *Fusarium vasinfectum*, by D. C. Neal; Progress in Soil-Contamination Studies With *Fusarium vasinfectum*, by A. L. Smith; Relation of Unbalanced Fertilization to the *Fusarium* Wilt of Cotton, by V. H. Young and W. H. Tharp; The Effects of Nitrogen Source, Nitrogen Level, and Relative Acidity on *Fusarium* Wilt of Cotton, and Effects of Nitrogen, Phosphorus, and Potassium Nutrition on the *Fusarium* Wilt of Cotton, both by W. H. Tharp and C. H. Wadleigh; and A Study of Virulence in Relation to Cultures of *Fusarium vasinfectum*, by E. M. Cralley.

The Plant Disease Reporter, [July 1 and 15, 1939] (U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr., 23 (1939), Nos. 12, pp. 203-208; 13, pp. 209-223, figs. 3).—The following are included:

No. 12.—Occurrence of spotted wilt in Missouri, by J. T. Middleton; muck crop diseases to date in New York State, including onion smut, downy mildew, and pink root, *Pythium* "stunt" of lettuce, and wind injury to lettuce and onions, by A. G. Newhall; losses from potato diseases in the Hastings section, Florida, in 1939, by A. H. Eddins; cotton diseases in central Texas, by C. H. Rogers; reports on X-disease (yellow-red virosis) of cherry and peach (on wild cherry in Massachusetts and on peach and choke cherry in New York); some records of first appearance or unusual occurrence (downy mildew on oats in Mississippi, flax wilt in Oregon, and blackfire of Perique tobacco in Louisiana); and brief notes on plant diseases, including stem nematode in strawberry fields in the Pacific Northwest, bacterial wilt on sweet corn in New York, and diseases of small grains in central Texas.

No. 13.—A survey of cotton seedling diseases in 1939 and the fungi associated with them, by P. R. Miller and R. Weindling; tobacco seed-bed disease survey in Wisconsin, 1939, by J. Johnson; some obscure peach diseases in Idaho, by E. C. Blodgett; first report of the popcorn disease (*Sclerotinia carunculoidea*) of mulberry in Arkansas, by J. C. Dunegan and E. J. Allen; vegetable disease notes in New York, by C. Chupp; incidence of potato leaf roll on Long Island, by W. G. Been; cereal diseases in Oregon and adjacent Washington in 1939, by R. Sprague; and bacterial ring rot of potato in Oregon, by C. E. Owens.

Fifty years of plant pathology research, W. B. TISDALE (Fla. Expt. Sta.). (Citrus Indus., 19 (1938), No. 11, pp. 8, 9, fig. 1).—This article briefly tells the history of problems in phytopathology which the Florida Station has had to combat during its first half century and of numerous solutions to these problems.

Plant pathology (Hawaii Sta. Rpt. 1938, pp. 34-42).—Progress reports are given on work by G. K. Parris with a new disease of papaya of possible virus nature, bean rust (*Uromyces phaseoli typica*), "ring spot" on tomatoes, early blight of potatoes, soft rot (*Pythium* sp.) and vascular necrosis of taro, and varietal resistance to these two troubles; by Parris and K. Kikula on root knot of tomatoes and potato seed piece rot control; and by Parris and J. C. Ripperton on ergot of *Paspalum* spp. due to *Claviceps paspali*, including Hawaiian localities where found; and a list of miscellaneous plant diseases in Hawaii (1937-38).

Plant diseases (Idaho Sta. Bul. 229 (1939), pp. 30-32).—Brief reports are included on the development of new beans possessing resistance to curly top and mosaic; demonstration of seed transmission of near-wilt of peas; fruit disease investigations, including cherry mottle leaf, gooseberry mildew control by sulfur fungicides, drought spot or gum spot of prunes associated with boron deficiency, and cyclamen mite infestation of strawberry plantings; and Katahdin potato seedlings showing resistance to virus diseases.

[Plant disease studies by the Indiana Station]. (Partly coop. U. S. D. A.). (Indiana Sta. Rpt. 1938, pp. 11, 37-42, 51, 52, 79, figs. 5).—Brief reports are included on the effect of black stem rust on the composition of wheat, by H. R. Kraybill and D. M. Doty; peppermint anthracnose control, and extremely early maturing of apple scab ascospores in 1938, both by R. C. Baines; seed transmission of tomato early blight, by R. W. Samson; tomato seed treatment, by Sampson and L. C. Shenberger; the taxonomy of plant rust fungi, by G. B. Cummins; wheat breeding for combined resistance to disease and Hessian fly, and effects on yield of seed treatment of smut-free oats, both by R. M. Caldwell

and L. E. Compton; root nematodes of tomatoes, by G. A. Ficht; and *Fusarium* wilt of China aster, by E. R. Honeywell.

Plant disease control, A. G. PLAKIDAS (*Louisiana Sta., Fruit and Truck Sta. Bien. Rpt. 1937-38, pp. 22-29*).—Reports of progress are given on strawberry diseases (late summer spraying for control of leaf blights, spray adjuvants, studies of the nature of resistance to leaf spot, the mode of action of bordeaux on *Mycosphaerella fragariae*, and two new leaf-spotting fungi—apparently undescribed species of *Cercospora* and *Mycosphaerella*); rosette on dewberries and blackberries due to *Cercospora rubi*; dying of pear and tung trees associated with *Dothiorella* sp.; *Phytophthora cinnamomi* root rot of tung trees; intervenal browning, translucent spot, and white tree abnormalities of tung trees; and control of downy mildew (*Pseudoperonospora cubensis*) of cucumbers.

Plant diseases (*Nebraska Sta. Rpt. 1938, pp. 32, 33*).—Brief reports are included on studies of scab, *Fusarium* wilt, and *Rhizoctonia* of potato, including breeding for resistance; bacterial blight of bean; and a seasonal plant disease survey for the State.

Fungus diseases and transpiration [trans. title], A. HILTZER (*Studia Bot. (Czechoslovakia, 1 (1938), No. 1, pp. 20-36*).—The author briefly reviews the literature (9 references) and presents the results of experiments on a large number of fungus-infected plant species of diverse groups. Except for three cases the diseased plants all exhibited an increased transpiration.

A small cage for insect vectors used in plant inoculations, N. J. GIDDING. (U. S. D. A.). (*Phytopathology, 29 (1939), No. 7, pp. 649, 650, fig. 1*).—A cloth-covered glass cage 22 mm. in diameter and 22 mm. high is held in place on a ground glass base by two stainless steel coil springs attached to brass cross-pieces under the base and over the top.

A method for testing the toxicity of volatile compounds, D. E. PRYOR and J. C. WALKER. (Univ. Wis. et al.). (*Phytopathology, 29 (1939), No. 7, pp. 641-643, fig. 1*).—The authors describe a transfer chamber and a glass plate on which a sterile agar film of uniform thickness may be poured. After hardening, identical disks are cut from this film with a sterile "biscuit cutter" and transferred to the inside of covers of containers such as Petri dishes or glass-top jars. The inoculum is deposited on the exposed agar surface, the material to be tested is placed in the desired amount and concentration in the bottom of the container, and the top is sealed. The toxicity of the volatile substance is then determined by its effect on the fungus growth.

Theoretical principles underlying laboratory toxicity tests of fungicides, F. WILCOXON and S. E. A. MCCALLAN (*Contrib. Boyce Thompson Inst., 10 (1939), No. 3, pp. 329-338, figs. 3*).—Toxicity curves are of two types, viz, those obtained by quantitative measurements of such properties as germ tube length or colony diameter and those in which the test divides individuals into two categories, as germinated and nongerminated spores. In the latter type the curves result from the fact that each spore has its own particular lethal dose, and there is a distribution of individual lethal doses which is usually normal when plotted against the logarithm of concentration. The problem in toxicity tests is to deduce the properties of the curve of individual lethal doses from the toxicity data obtained. These methods lead to an estimation of the LD50 value (concentration preventing 50 percent germination), and the range within which it may be expected to lie 19 out of 20 times. The methods may be extended to give an estimate of the LD95 and its corresponding zone of error. In comparing fungicides that have been run at different times or in different laboratories, they should be rated in terms of a standard run simultaneously with the unknown to reduce errors from many obscure causes.

The fungicidal activity of phenothiazine and some of its oxidation derivatives, M. C. GOLDSWORTHY and E. L. GREEN (*Phytopathology*, 29 (1939), No. 8, pp. 700-716, fig. 1).—Analysis of the results of various perfusion, residue, and orchard-spraying experiments indicates that phenothiazine (hitherto known as an insecticide) and its known oxidation derivatives are a fungicidally interesting group, and the data show that for this purpose phenothiazone is the most important member. Field spray tests over a period of several years have demonstrated that phenothiazine, with or without adjuvants, is of value against apple scab, and laboratory studies have indicated that it is also toxic to the fungi of peach brown rot and apple bitter rot. Laboratory tests of its oxidation derivatives—phenothiazine sulfoxide, phenothiazone, and thionol—indicate that the active principle of phenothiazine is phenothiazone, and that the latter is toxic to *Sclerotinia fructicola* and *Glomerella cingulata* in dilutions as low as 2.5 p. p. m. by volume in water. Limited phytocidal tests on two peach varieties with phenothiazine sulfoxide, phenothiazone and thionol resulted in no injury to leaves or bark (no data on fruit).

Alkaloids from *Sanguinaria canadensis* and their influence on growth of *Phymatotrichum omnivorum*, G. A. GREATHOUSE. (U. S. D. A. and Tex. Expt. Sta.). (*Plant Physiol.*, 14 (1939), No. 2, pp. 377-380).—Sanguinarine, chelerythrine, and protopine were isolated from the roots and rhizomes of *S. canadensis*, and the first was shown experimentally to prevent the growth of *P. omnivorum* at 2.5 p. p. m. while the other two alkaloids proved less toxic. The evidence presented is believed to indicate that alkaloids play an important role in the resistance of *S. canadensis* to *Phymatotrichum* root rot.

The number of spores in a pycnidium of *Septoria apti*, K. H. LIN. (Cornell Univ.). (*Phytopathology*, 29 (1939), No. 7, pp. 646, 647).—Using a "counting field," the spores of 9 pycnidia were separately counted, averaging 3,675 each. The average number of pycnidia per leaf spot was found to be 56. It was estimated that if only 10 primary lesions occurred in a seedbed there would be possibly 1,500,000 spores available as secondary inoculum before the plants were set in the field.

Identity and parasitism of a species of *Dothichloë*, W. W. DIEHL. (U. S. D. A. et al.). (*Jour. Agr. Res.* [U. S.], 58 (1939), No. 12, pp. 947-954, pl. 1).—*D. limitata* n. sp. is described, with an account of its known distribution from North Dakota to Brazil and its host range in eight grass genera. Field observations and experiments indicate that low temperatures inhibit the fungus fructifications, and that infection is systemic with resultant sterility but without obvious lesions or strikingly abnormal coloration of affected grasses.

Studies of boron deficiency in Idaho soils, W. E. COLWELL and G. O. BAKER. (Idaho Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 6, pp. 503-512, figs. 5).—"A greenhouse method suitable to detect boron-deficient soils is described. A good correlation was obtained between greenhouse and field experiments. Preliminary field tests in northern Idaho indicate that fall applications of borax at the rate of 40 to 60 lb. per acre are superior to spring applications in overcoming yellowing in alfalfa. The results of a limited number of analyses on alfalfa indicate that a high boron content of alfalfa is associated with freedom from yellowing. The investigations are of preliminary character. Further work is being done to substantiate these findings."

Studies on the susceptibility of forage grasses to cereal smut fungi.—III, Further data concerning *Tilletia levis* and *T. tritici*, G. W. FISCHER. (U. S. D. A., Wash. Expt. Sta., et al.). (*Phytopathology*, 29 (1939), No. 7, pp. 575-591, figs. 2).—Continuing this series (E. S. R., 81, p. 382), inoculation tests on various grass species of the tribe *Hordeae* have added *Agropyron*

inermis, *A. spicatum*, *A. trichophorum*, and *Sitanion jubatum* as new hosts of *T. levis* and *T. tritici*. Tested on *A. cristatum* and *A. pauciflorum*, physiologic races of these 2 bunt fungi differed greatly in virulence. In comparative tests of their virulence, as species, on these 2 grasses, *T. levis* was ± 35 percent more virulent on *A. cristatum* but slightly less so on *A. pauciflorum*. Much greater differences were noted in the reactions of the 36 selections of the 2 grasses to the smut races than in the relative virulence of the latter. Although none of the 20 selections of *A. cristatum* were immune to *T. levis*, a few were highly resistant. On the other hand 8 of the 16 selections of *A. pauciflorum* were apparently immune to all 8 races of *T. levis*. Other selections of the 2 hosts were moderately susceptible to more or less resistant. The same selections proving resistant to *T. levis* were, in general, also resistant to *T. tritici*. Of the 2 grasses, *A. cristatum* as a species was the more susceptible to wheat bunt. The evidence indicates the mycelium of the 2 fungi to be perennial in perennial hosts, though not indefinitely. Of 90 plants of *A. cristatum*, *A. pauciflorum*, *A. subsecundum*, and *Hordeum nodosum* showing smut in 1935, 39 had in some manner been freed of infection during the 2 succeeding years, 7 had died, and 44 still retained the infection in 1937. In general, it is deemed probable that the duration of perennation of the mycelium of these smuts in their perennial hosts will be influenced by the degree of susceptibility of the host, and by its predisposition to drought or winter injury. It is noted that smut balls of *T. tritici* were found in a sample of sweetclover seed, but obviously from some grass, this being recorded as the second instance of its natural occurrence on a forage grass. It was observed that bunted plants resulting from infection with *T. tritici* tended to be more or less stunted.

Inoculation experiments with loose smuts of wheat and barley (*Ustilago tritici* and *U. nuda*), A. J. P. OBER (*Phytopathology*, 29 (1939), No. 8, pp. 717-728, figs. 4).—Inoculations of wheat and barley with *U. tritici* and *U. nuda*, respectively, were made by modifications of Moore's method (E. S. R., 75, p. 639) which are fully described. Under the experimental conditions the loss of plants at emergence and during winter was slight—a total of only 10 percent for wheat regardless of inoculation period or concentration of spore suspension. In barley there was some relation between loss of plants and the last two factors, yet the total maximum loss did not reach 20 percent. There appeared to be no relation between the occurrence of partly diseased plants and the period of inoculation or the concentration of the spore suspension. The optimum period for infection lasted only a few days and during anthesis. The spore inoculum had a maximum effect for wheat and for barley at concentrations of 1 and 0.1 gm. spores per liter of water, respectively. At concentrations of ± 0.001 gm. spores per liter, or ± 10 spores per cubic millimeter, a fairly good infection occurred. With increase of pump strokes from 2 to 10 the number of smutted plants increased (tested with wheat only). Whether the maximum is already reached at 10 pump strokes is uncertain, but for practical reasons a larger number is not recommended.

The effects of stinking smut (bunt) and seed treatment upon the yield of winter wheat, T. A. KESSELBACH and W. E. LYNES (*Nebraska Sta. Res. Bul.* 110 (1939), pp. 23).—Annual tests (9 yr.) of the relationship between infection with the races of *Tilletia levis* prevailing in Nebraska and the grain yield of a standard susceptible winter wheat variety (Kanred) indicated a rather regular decrease in weight per bushel with increasing infection (ascribed to the greater proportion of bunt balls in the threshed grain) and a rather close inverse relation between the annual and the average bunt counts and the yields. Of the various fungicides tested (3-8 yr.) copper carbonate and

New Improved Ceresan dusts proved most practical and were highly effective in bunt control without seed injury. Formaldehyde in proper dosage (immersion or sprinkling) gave effective control but induced sufficient seed injury to lower the yield significantly. Of 115 lots of medium to highly bunted seed receiving the recommended treatments, only 10 gave bunt-free crops, the others ranging up to 9.6 percent bunted heads. Treatment during 2 successive years is thus apparently needed for a complete clean-up, with further treatments at frequent intervals suggested to retain a bunt-free condition. Removal of bunt balls by a fanning mill in connection with seed treatment ($\frac{1}{4}$ yr.) lowered the bunt infection more than with the treatment alone. It was found that with heavily infected, unfanned wheat the seed may become reinfected after treatment by rough handling, causing the rupturing of bunt balls with viable contents.

In a nursery, heavy infection of nearly bunt-free seed was induced by using bunt balls taken from other wheat after fungicidal treatment. Deep planting of heavily bunted seed increased the infection in the resultant crop by 40 percent and lowered the yield 38 percent as compared with shallow planting—attributed to differing temperature conditions. The great increase in bunt infection following a 3 weeks' later sowing is attributed to the lower soil temperature at that time which is more favorable for bunt development. All progenies from spontaneously inoculated seed wheat up to 7-year-old seed developed bunt, and when healthy seed was inoculated with bunt varying in age up to 7 yr. the resultant crop also developed bunt. As an average of three tests in 1928, an increase of 36.2 percent bunted heads lowered the straw yield only 0.3 percent, whereas the grain yield was reduced 29 percent. As an average for 4 yr., the new bunt-resistant Nebred variety, selected and distributed by the station, produced only 0.6 percent bunted heads from inoculated seed as compared with 14.8 percent for similarly bunted seed of a standard variety.

Stem rust destructive to spring wheat in 1878, L. M. HAMILTON (*U. S. Dept. Agr., Bur. Ent. and Plant Quar., 1939, pp. 11*).—"Although pioneer farmers of the Middle West knew that the presence of stem rust on their grain meant reduction in yield, accurate rust observations were not made until comparatively recently. There were severe epidemics in 1916 and in 1904, but previous to this reports of rust are scattered and little is known regarding epidemics. The present report represents an attempt to summarize material regarding 1878, one of the early rust years. Because of nonavailability of material, it has been necessary to restrict discussion largely to Minnesota."

Brown necrosis, a discoloration associated with rust infection in certain rust-resistant wheats, E. S. McFADDEN. (*U. S. D. A. and Tex. Expt. Sta.*). (*Jour. Agr. Res. [U. S.], 58 (1939), No. 11, pp. 805-819, figs. 4*).—The author presents experimental data, together with evidence from the literature (13 references), apparently demonstrating that much of the so-called black chaff disease (previously confused with other diseases, particularly bacterial black chaff) reported in Hope and H-44 wheats and their rust-resistant derivatives is merely a manifestation of resistance to stem rust. Infection before the host tissues had been long exposed to sunlight resulted in the development of pigmented areas ("brown necrosis") in certain wheats such as these two varieties, which possess a specific type of mature-plant resistance to stem rust, while rust-susceptible varieties and those with other types of resistance remained free from this melanistic reaction. Two distinct types of mature-plant resistance to stem rust ("photologic" and "morphologic") were found to segregate from the cross H-44 \times Marquis. Brown necrosis developed only in plants with the photologic type, which possibly may explain previous reports of close

but incomplete "linkages" and "associations" of stem rust resistance with susceptibility to the so-called black chaff. Inoculations of F₂ plants from H-44 × Marquis wheat demonstrated that the brown necrosis reaction can be used as an indicator for identifying plants carrying the factor for photologic resistance prior to the blooming period, thus simplifying breeding for rust resistance by the backcross method.

The effect of salicylic aldehyde on the infection of wheat by *Pythium arrhenomanes* Drechsler, and the destruction of the aldehyde by *Actinomyces erythropolis* and *Penicillium* sp., V. E. GRAHAM and L. GREENBERG (*Jour. Bact.*, 38 (1939), No. 1, p. 116).—An abstract of an article previously noted (*E. S. R.*, 81, p. 226).

Factors affecting the development of *Puccinia coronata* in Louisiana, I. L. FORBES. (La. State Univ.). (*Phytopathology*, 29 (1939), No. 8, pp. 659-684).—*P. coronata* urediospores rapidly lost their germinability when kept at -18° or 33° C., but when stored at 10° up to 8 percent germinated after 413 days. At 4°, 15°, and 20° urediospores rather quickly lost their viability. Exposed to summer field conditions at Baton Rouge, La., they did not germinate after 75 days. Since there were no oats or susceptible wild grasses at Baton Rouge from July 1 to October 1, 1933, and since fall-planted oats do not rust before late December, it is concluded that crown rust inoculum is blown in from other regions. The minimum, optimum, and maximum temperatures for urediospore germination were 0°-2°, 15°-20°, and slightly below 35°, respectively. Rust developed on plants incubated at 0°-2° and postincubated at 20°, but failed to do so on plants incubated at 10° or 20° and postincubated at 0°-2°. The blue and to a lesser extent the violet rays are held responsible for the negatively phototropic response of urediospore germ tubes to white light in the rusts thus tested, viz, *P. coronata*, *P. graminis avenae*, *P. graminis tritici*, and *P. triticea*. The germ tubes of *P. coronata* seemed to enter the host without difficulty, either in light or darkness. The minimum pH for crown rust urediospore germination was ±2.7, the optimum 6.7, and the maximum 9.2. Oat variety reactions to crown rust were studied under field conditions in Minnesota and Louisiana. the most highly resistant variety during the 3-yr. tests being Victoria. Bond was immune in the field at Baton Rouge in 1933 and 1934. Extracts from the highly resistant Victoria and from the immune Bond (immune to attack by the rust forms used) markedly reduced the percentage of urediospore germination over that in controls and in extracts from the susceptible variety Victory, and also induced much distortion of germ tubes and delayed their growth rate. There are 43 references.

Early Blackhull resists stem rust in Texas, E. S. McFADDEN. (U. S. D. A. and Tex. Expt. Sta.). (*Phytopathology*, 29 (1939), No. 7, pp. 644, 645).—This winter wheat proved moderately resistant in the field to *Puccinia graminis tritici* at several experimental stations in Texas where 10 physiologic races were known to be present, the variety remaining relatively free from the disease for about 2 weeks after certain other varieties had become heavily infected. Shortly before ripening, and too late for much injury, Early Blackhull may develop considerable rust as small, distinctly isolated pustules. An occasional F₂ segregate from crosses between this variety and wheats possessing the Hope type of mature-plant resistance proved resistant both early and late in its growth cycle.

Prevalence of *Basisporium gallarum* in arrested axillary shoots and secondary ears of maize, J. H. STANDEN. (Iowa Expt. Sta.). (*Phytopathology*, 29 (1939), No. 7, pp. 656, 657).—Arrested axillary shoots of corn were found infected up to 42.3 percent in field samples in 1937, and up to 80.59 percent

in 1938. Secondary ears were much more frequently infected than primary ears, infection in the former being favored by poor development.

Pythium root rot of milo and the development of resistant varieties, J. B. KENDRICK and F. N. BRIGGS (*California Sta. Bul.* 629 (1939), pp. 18, figs. 7).—This destructive disease (*P. arrhenomanes*) has been recognized in the upper delta region of the Sacramento River since 1935. Now widespread, it is said to be the limiting factor in production of the common varieties in this area. Spread occurs by overflow water, irrigation, or transfer of infested soil by any other means. The roots are destroyed in the seedling stage or, in less severe attacks, the plants become stunted and weakened. A greenhouse variety test indicated Double Dwarf Darlo, a new variety developed by the station, to be highly resistant, on most soils comparing favorably with Double Dwarf Yellow in yield but with the disadvantage of being about 2 weeks later in some sections and less tolerant of alkali and heat than the latter. Badly diseased commercial fields of Double Dwarf Yellow and Dwarf White milos showed a few apparently normal plants, and single-plant selections of these two varieties were made in severely diseased commercial plantings in 1938. Greenhouse trials in spontaneously infested field soil (1936-37) showed most of these strains to be highly resistant, and the results were later confirmed in extensive field tests. A considerable number of heads were bagged in the field to secure pure-line resistant seed, and further greenhouse and field trials indicated the selected strains to be practically 100 percent resistant. Considerable resistant seed from the Double Dwarf Yellow milo selections is now available and is being distributed through the Calapproved plan as Double Dwarf Milo 38. Resistant strains of Dwarf White and Helleman are to be increased for distribution under the same plan.

Penetration of potato-tuber tissue by *Rhizoctonia solani* in relation to the effectiveness of seed treatment, L. A. SCHAAAL. (U. S. D. A.). (*Phytopathology*, 29 (1939), No. 8, pp. 759, 760, fig. 1).—Seed potatoes treated with mercury compounds gave incomplete control of *R. solani* as tested in Maine, and culture of the tuber tissue under sclerotia killed by the treatment showed viable mycelium therein. Cross sections indicated the mycelium to have invaded the periderm and tissues below it, probably thus offering sufficient protection to prevent killing of all of the fungus by tuber disinfectants.

Occurrence of hopperburn resistance and susceptibility in the potato, T. C. ALLEN and G. H. RIEMAN. (Wis. Expt. Sta.). (*Amer. Potato Jour.*, 16 (1939), No. 6, pp. 139-142).—Study of the behavior of new and old varieties of potato toward hopperburn (due to *Empoasca fabae*) indicated that the early maturing varieties are, in general, more susceptible. It is thought that the tolerance shown by the two recently introduced varieties Houma and Katahdin may readily account, in part, for the heat and drought resistance attributed by various investigators to these two varieties. By selecting normal and hopperburn-injured individual plants in segregating seedling populations grown under epidemic conditions in the field, it was possible to separate segregates into two distinct levels of hopperburn tolerance. A number of seedling cultures were isolated which showed a greater degree of resistance and of susceptibility to hopperburn than any of the new or old varieties tested. The relative percentages of hopperburn resistance and susceptibility were based on the ratio of necrotic hopperburn tissue to healthy green tissue in the various potato leaf tissues considered.

[Rice disease studies.] (Partly coop. U. S. D. A.). (*Louisiana Sta., Rice Sta. Bien. Rpt.* 1937-38, pp. 19, 20, 23-28, figs. 3).—Brief reports are given on studies of rice diseases, including pecky rice (high percentages correlated with

Helminthosporium infection), by T. C. Ryker and W. A. Douglas; and disease surveys—1937-38, root rot, *Cercospora* leaf spot, banded sclerotial disease, leaf blotch—a new disease associated with a sterile fungus, and white tip control, all by Ryker.

Relative efficiency of quasi-factorial and randomized-block designs of experiments concerned with damping-off of sugar beets, E. L. LeCLERC. (U. S. D. A. and Minn. Expt. Sta.). (*Phytopathology*, 29 (1939), No. 7, pp. 637-641, fig. 1).—"The quasi-factorial design of plat arrangements was more efficient than a randomized-block test in some seasons for damping-off tests with sugar beets, with 36 treatments, in the field. With 25 or fewer treatments, the quasi-factorial design was less efficient in most comparisons, although it was more efficient in a few. In greenhouse experiments, made on two types of plant beds, marked losses in efficiency resulted with quasi-factorial design as compared with a randomized-block arrangement."

Recovery from and acquired tolerance of curly top in *Nicotiana tabacum*, J. M. WALLACE (*Phytopathology*, 29 (1939), No. 8, pp. 743-749, figs. 4).—Diseased plants commonly recovered from severe symptoms by the gradual production of less severely affected leaves from the severely diseased terminal, or by producing axillary shoots free of symptoms or nearly so. Plants grown from cuttings from recovered cases showed a slight variation in symptoms from time to time, but in no instance did they relapse permanently into a stage equaling the typical symptoms produced by inoculation of healthy plants via beet leafhoppers. Virus was found in recovered plants and in plants of the fourth vegetative generation. Cuttings grown from recovered plants showed no effects when reinoculated with the virus. Recovery from one strain of virus conferred protection against another strain as well as against mixed, unidentified strains. Recovery of tobacco from curly top and the acquired tolerance associated with it is said to resemble in many respects that reported for ring spot of tobacco and curly top of tomato. It is suggested that acquired tolerance following recovery of plants from virus diseases may offer the best material yet available for studying the nature of immunological-like phenomena in plants.

Viscosimetric studies on the tobacco mosaic virus protein, I, V. L. FRAMP-
TON. (Cornell Univ.). (*Jour. Biol. Chem.*, 129 (1939), No. 1, pp. 233-244, figs. 8).—"An adaptation of the Ostwald viscometer is described. Sols of the virus protein show a marked anomalous viscosity which increases on decreasing the pH of the solution. The anomaly shown by sols of the virus protein is greatly reduced in the presence of urea and glycine. The virus activity of the virus is not immediately affected on the addition of urea or glycine. The application of the Kuhn equation to this protein has been shown not to be valid."

Studies on the nature of brown root rot of tobacco and other plants. J. JOHNSON. (U. S. D. A. and Univ. Wis.). (*Jour. Agr. Res. [U. S.]*, 58 (1939), No. 11, pp. 843-863, pls. 2, figs. 5).—"The true nature of this disease is held to be unknown, though it occurs on a wide variety of plants and on tobacco most frequently following certain grass or legume crops. The legume family is particularly susceptible, but susceptibility is apparently not correlated with the origin or persistence of the inciting agent in the soil. The experiments here reported were conducted in the greenhouse, largely on soils from Massachusetts. The causal agent was found to be relatively slow in its action on the roots and, as judged by dilution experiments, not highly concentrated in the soil. Whatever the agent, it is destroyed in 24 hr. at 45° C., by freezing, by desiccation, and by certain chemicals, some of which are relatively low in germicidal value at the concentrations used. Powdered charcoal and soil (2-100) also eliminated the disease. Reduction of the causal agent in the soil apparently depends

largely on exposure of soils (cultivated soils in particular) to extremes of heat, cold, and drought. Histological and cytological study of diseased tissues failed to reveal any associated organism. Diseased cells were usually sharply delimited from normal cells, and affected cell walls were yellow and thickened, with cell contents discolored and granular. The lesions may be superficial or may extend to and follow the stele. No new theory as to cause of brown root rot is offered, but it is thought that the data presented should aid materially in further studies on its etiology. There are 18 literature references.

Recognizing and treating the common greenhouse vegetable diseases and a description of two diseases new to Ohio, L. J. ALEXANDER. (Ohio Expt. Sta.). (*Ohio Veg. and Potato Growers Assoc. Proc.*, 24 (1939), pp. 55-60).—A general discussion, with special reference to virus diseases and to two diseases new to Ohio greenhouse plants, viz, the virus-induced Australian spotted wilt and bacterial stalk rot of tomato.

New equipment and new materials for controlling vegetable diseases, J. D. WILSON. (Ohio Expt. Sta.). (*Ohio Veg. and Potato Growers Assoc. Proc.*, 24 (1939), pp. 110-134).—Progress in designing and construction of a much needed small power-driven spraying and dusting equipment for vegetable growers operating 5-20 acres is reported. The work on vegetable disease control involved comparisons of the insoluble copper compounds with one another and with bordeaux mixture, and progress along these lines is reported. As tested on tomatoes, there was little to choose between 4-4-50 and 4-2-50 bordeaux. Both formulas and Coposil all caused considerable injury to young plants. Bordeaux (4-4-50) and Grasselli Copper Compound-A gave the best control of anthracnose fruit rot on the canning crop. Sprays delayed until *Septoria* leaf spot appeared gave fair control and increased the yield of staked tomatoes. On cucumbers, those mixtures containing an insoluble copper as one ingredient gave better control of bacterial wilt than others in which these coppers were absent. A number of materials were tested on muskmelons, Cupro-K giving the best results on the basis of salable melons. The melons ripened later on many of the large, healthy vines treated with certain of the insoluble coppers. The results with potatoes, beans, celery, and carrots, though favorable from the standpoint of disease control and plant injury, made it seem inadvisable to recommend the use of insoluble coppers as bordeaux substitutes on these crops, largely due to the greater costs.

Injuries following greenhouse soil sterilization: Cause and control, I. C. HOFFMAN. (Ohio Expt. Sta.). (*Ohio Veg. and Potato Growers Assoc. Proc.*, 24 (1939), pp. 60-64).—The accumulation of ammonium carbonate following soil sterilization—injurious to many plants—is reported preventable by application of CaSO_4 .

A new disease of snap beans, W. A. JENKINS. (Ga. Expt. Stat.). (*Science*, 90 (1939), No. 2325, p. 63).—This severe chlorosis followed by wilt and death of the plant was first noted by the author in 1938, and during the current season has been even more destructive. The disease appears to have been brought in on western-grown seed and is believed not to have been hitherto described. The evidence thus far at hand suggests a virus origin.

Dwarfing of cucurbits sprayed with bordeaux mixture, J. G. HORSFALL, G. E. R. HERVEY, and R. F. SUTT. (N. Y. State Expt. Sta. et al.). (*Jour. Agr. Res.* [U. S.], 58 (1939), No. 12, pp. 911-927, figs. 7).—Bordeaux mixture was found to induce six distinct types of injury on cucurbits, viz, dwarfing, leaf deformation, leaf-margin yellowing followed by necrosis, scorching of leaf lamina, accelerated transpiration, and defoliation. The dwarfing and leaf-deformation aspects were studied in greenhouse tests during the winter and

some of the conclusions were checked during summer (1936-38). The lime portion of the bordeaux definitely dwarfed the plants and deformed the leaves, while the copper portion did not appear to be involved unless solubilized by low pH values. An increased spray load (amount of material per 50 gal. of spray, i. e., 2-2-50, 4-4-50, 6-6-50, etc.) increased the injury. The most significant factor in dwarfing and leaf deformation appeared to be the pH value of the spray. When it was shifted very far from neutral, dwarfing was increased whether or not copper was present. Based on the available data, it is suggested that the dwarfing may be due to (1) physiological drought in the tissues induced by the effect of bordeaux transpiration, (2) to the action of Ca ions in hardening the tissues, or (3) to reduced photosynthesis, or to a combination of these causes. Some of the so-called inert diluents caused injury to cucurbits. The safest diluents tried were diatomaceous earth, gypsum, talc, and wheat flour. Calcium arsenate appeared to be a satisfactory insecticide from the standpoint of safety. From the practical standpoint the data obtained indicate that both acid and alkaline sprays or dusts should be avoided on cucumbers and melons, and that a neutral bordeaux is impractical because the margin of safety is too narrow. "One of the insolubilized copper compounds would be preferable, although some of these are less satisfactory than others."

Studies on "damping off" of cultivated mushrooms and its association with *Fusarium* species, II, F. C. Wood (*Phytopathology*, 29 (1939), No. 8, pp. 728-739, figs. 4).—Continuing these studies (E. S. R., 77, p. 348), evidence is adduced to indicate that when the casing soil has been infested with *Fusarium* it is antagonistic to mushroom (*Agaricus*) spawn. It is further shown that, if due allowance be made for the large discrepancy in growth rates between *Fusarium* spp. and *Agaricus*, a well-established *Agaricus* culture is also intensely antagonistic to *Fusarium* spp. An antagonistic effect, its intensity depending on the time of inoculation, was shown by watering growing mushrooms with extract from cultures of *Fusarium* spp. grown in Richard's solution. The deleterious effects of oxygen deficiency on both fungus types is shown. The thermal death point of the common *Fusarium* species causing damping-off was determined, and it is suggested that soil sterilization is the best method known for avoiding this mushroom disease.

Movement of tobacco-mosaic virus in tomato plants, L. O. KUNKEL (*Phytopathology*, 29 (1939), No. 8, pp. 684-700, figs. 2).—Under the experimental conditions, the virus never began movement out of inoculated tomato leaflets in 42 hr. or less, but occasionally moved throughout the stem of a plant in 44 hr., though the interval required varied greatly with different individuals. On first reaching the stem from an inoculated leaflet, the virus usually moved both upward and downward, though sometimes downward only and occasionally upward only. No evidence was obtained to support the idea that virus passage from an inoculated leaf to the tip of a plant is via the roots, and proof was given that it did not follow such a course in certain plants. When movement from an inoculated leaflet began, the virus traveled rapidly—sometimes at a rate of 7 in. or more per hour. Samuel's observations (E. S. R., 71, p. 337) that in the earliest stages of entering the stem virus particles may be separated by considerable distances was fully confirmed. The particles must pass through long chains of cells without infecting. This movement cannot, therefore, result from propagation by means of an autocatalytic reaction. Virus particles remaining for some time dormant in sections of tomato or tobacco stems may move out into plants grown from such sections and there multiply and cause disease.

Hybridization of a mosaic-tolerant, wilt-resistant *Lycopersicon hirsutum* with *Lycopersicon esculentum*, W. S. PORTE, S. P. DOOLITTLE, and F. L. WELLMAN. (U. S. D. A.). (*Phytopathology*, 29 (1939), No. 8, pp. 757-759, fig. 1).—A recent introduction of *L. hirsutum* from South America produced a fertile hybrid on the Marglobe and Bonny Best varieties of tomato. This hybrid is of particular interest because *L. hirsutum* appears to be highly tolerant to tobacco mosaic virus and also resistant to wilt (*Fusarium bulbigenum lycopersici*).

Physiological drop in apples, L. R. DETJEN. (Del. Expt. Sta.). (*Md. State Hort. Soc. Proc.*, 41 (1939), pp. 20-26).—A general discussion of fruit-bud initiation and development as depending on good culture, winter-killed and retarded buds, improper pollination, embryo abortion, the comparative significance of the several waves of drops when numbers alone and mass alone are considered, comparative importance of the physiological drop, and preripe drops.

Spraying of apples, with special reference to effects on foliage and fruit, L. A. STEARNS. (Del. Expt. Sta.). (*Md. State Hort. Soc. Proc.*, 41 (1939), pp. 57-62).—A general discussion, with brief summary of recent data.

Unusual development of apple perennial canker following application of toxic wound dressings, E. L. REEVES, M. A. YOTHERS, and C. W. MURRAY. (U. S. D. A.). (*Phytopathology*, 29 (1939), No. 8, pp. 739-743, fig. 1).—Of several hundred kinds of wound dressings tried, a few, applied to cleaned-out perennial canker lesions on Jonathan apple branches, caused injury to the bark surrounding the cankers, and *Gloeosporium perennans* invaded the bark so injured. Under average field conditions in north-central Washington, this fungus normally invades new bark tissues only during a relatively short period about the time tree growth starts and providing conditions are favorable for such development. The unusual feature here was the fact that the fungus advanced and fruited on the injured tissues during the hottest period of the year, at a time when it is difficult to obtain successful artificial inoculations and when, under ordinary circumstances, the pathogen is most inactive. The fungus also advanced into tissues containing a total average of 256 p. p. m. As_2O_3 .

The effect of sulfur fungicides on the photosynthesis and respiration of apple leaves, R. A. HYBE ([New York] *Cornell Sta. Mem.* 222 (1939), pp. 40, figs. 5).—In these experiments (methods described), all spray materials used on McIntosh and Baldwin apple leaves under controlled conditions decreased the apparent photosynthesis during the test period (2½ days), the principal reduction due to lime-sulfur solution with or without lead arsenate occurring when the lower leaf surfaces were sprayed. The reduction from spraying both surfaces or the lower surfaces only was ± 24 percent, and that from spraying the upper surfaces only was ± 5 percent. The sprayed leaves throughout showed slight but not significant increases in respiration. The mean reduction in apparent photosynthesis (± 10 percent) from four treatments (three sulfur-fungicide and one control) was essentially the same at 70° and 85° F., while that at 100° was ± 25 percent—the last highly significant. At 85° bordeaux mixture gave less reduction in apparent photosynthesis than any of the sulfur sprays tested, the wettable sulfurs being next in order. Koppers Flotation Sulphur Paste gave the least reduction of the wettable sulfurs, and significantly less than the Magnetic Spray Wettable Sulphur. The other differences in wettable sulfurs were not significant. Lime-sulfur solution gave a significantly greater reduction in apparent photosynthesis than the wettable sulfurs. Lead arsenate added to two wettable sulfurs and to lime-sulfur solution gave a slightly greater but not significant mean reduction in apparent photosynthesis than these sprays without it. Addition of both hydrated lime and lead arsenate to these three sulfur sprays gave a greater mean reduction than without them

or with the lead arsenate alone, also differences not significant. Addition of Magnetic Catalytic Sulfur to lime-sulfur solution (1-100) plus lead arsenate gave the least reduction of all lime-sulfurs tested, but the number of replications was too small to indicate the significance. Addition of Magnetic Spray Wettable Sulphur to lime-sulfur solution (1-100) plus lead arsenate gave a slightly greater but not significant reduction than lime-sulfur (2-100) plus lead arsenate.

In this study the leaf treatments decreased the apparent photosynthesis and increased the respiration of Baldwin more than McIntosh leaves. The apparent photosynthesis of the untreated leaves was significantly less during the second 6½-hr. period of the day than during the first. Twenty-two references are included.

Relation of drought spot of prunes to boron content of fruit, E. C. BLODGETT and W. E. COLWELL. (Univ. Idaho). (*Phytopathology*, 29 (1939), No. 7, pp. 650, 651).—In this preliminary note drought injury to prunes, especially the spot form, is reported to be common and frequently serious in Idaho. Analyses of spotted and normal fruits indicated a definite correlation between such injury and a low boron content of the fruit and pit tissues.

Papaw mosaic disease, R. E. D. BAKER (*Trop. Agr. [Trinidad]*, 16 (1939), No. 7, pp. 159-163, pls. 4, fig. 1).—A general account (12 references), including symptoms, possible causes (probable virus etiology), work with insects (aleyrodid flies suspected as vectors), and control.

Some observations on psorosis in the light of experience of 25 years, J. C. PERREY (*Calif. Citrog.*, 24 (1939), No. 8, pp. 276, 290, 291, 292, 293).

Root-knot nematode injury restricted by a fungus, M. B. LINFORD and F. YAP. (Hawaii. Pineapple Prod. Expt. Sta.). (*Phytopathology*, 29 (1939), No. 7, pp. 596-609, fig. 1).—Pineapple, *Ananas comosus* (Cayenne var.), slips were grown 15 mo. in pots of sterilized soil infested with *Heterodera marioni* larvae, both with and without cultures of five fungus species found to capture and kill various nematodes on agar. Heavy spontaneous infestations with such fungi (where no cultures had been added) prevented measurements of the full degree of beneficial effects of the introduced fungi, but the root knot injury as measured by leaf and root growth was significantly least where *Dactyliella ellipsospora* had been added. The following fungi proved no more effective than the chance fungus infestation in which *D. ellipsospora* was dominant: *Arthrobotrys musiformis*, *A. oligospora*, *Dactylaria candida*, and *D. thaumasia*. Where added experimentally, each fungus dominated the chance contaminants and was reisolated from a large proportion of the pots after 15 mo.

The resistance of elms to Graphium ulmi [trans. title], G. ARNAUD (*Ann. Epiphyt. et Phytogénét.*, n. ser., 5 (1939), No. 1, pp. 41-49, figs. 3).—Experiments at Versailles are said to confirm the results reported by various investigators and to warrant the following conclusions: At the end of 10 yr. under test, 2 out of 50 seedling trees (*Ulmus campestris* forms) remained healthy under conditions very favorable to infection. The vigorous trees suffered relatively more after infection. Trees attacked only in their upper portions were cured by removal of affected parts and grew again vigorously, indicating that the basal parts were intact. However, such trees may be reinfected, there being no indication of immunity following attack. The role of *Scolytus* in transmitting *G. ulmi* generally accepted by most observers is considered possible, but certain doubts are raised concerning it.

Botrytis blight of Antirrhinum related to trichome disposition, F. P. MCWHORTER. (Oreg. Expt. Sta. and U. S. D. A.). (*Phytopathology*, 29 (1939), No. 7, pp. 651, 652, fig. 1).—In greenhouse plants of two varieties of *A. majus*, glandular trichomes are reported to have served apparently as effective courts

of infection, either because they retained moisture or because of some inherent property rendering them suitable media for the cinereal form of *Botrytis* concerned.

Anthracnose of Lippia. R. C. BAINES and C. B. CUMMINS. (Ind. Expt. Sta.). (*Phytopathology*, 29 (1939), No. 7, pp. 654-656, fig. 1).—*Sphaceloma lippiae* n. sp. is described on *L. lanceolata* collected at North Liberty, Ind. This species resembles *S. menthae* in habit, but has smaller conidia and differs in parasitism as proved by inoculations.

Studies on narcissus mosaic. F. A. HAASIS ([New York] Cornell Sta. Mem. 224 (1939), pp. 22, pls. 2).—This mosaic is said to be widely distributed, and its destructiveness is evidenced by the fact that diseased plants produce low-grade flowers and small, inferior bulbs. It is characterized by stunting, light green to greenish yellow striping, mottling, and marbling of the foliage and flower stem, by epidermal roughening of the foliage and occasionally of the flower stem also, by distortion of the foliage and occasionally of the flower parts, and by opaque, frostlike streaks and spots on the perianth and cup of the flower. Mosaic is due to a virus transmissible by bulb grafts, by mechanically injecting or rubbing sap from leaves of affected plants into or on leaves of healthy plants, and by propagation of mosaicked bulb stock, but probably not by soil contamination, by root contact, or through the seed. Transmission by root mutilation and by cutting or picking the flowers is said to be negligible. The symptom expression varies greatly among narcissus varieties, but intervarietal inoculations indicate that the disease is probably due to a single virus. The virus resists aging in vitro for at least 72 hr., is transmissible at a dilution of 1-100, is inactivated by 70°-75° C., and fails to pass Pasteur-Chamberland filters of grades L₂, L₃, and L₄. Based on morphological symptoms, plants other than narcissuses appear to be highly resistant or immune to this virus. Thus far the most satisfactory control method is to rogue and destroy affected plants or to protect healthy plants from inoculation by means of fine-mesh cheesecloth cages.

Phytophthora stem rot of Viscaria. R. C. BAINES. (Ind. Expt. Sta.). (*Phytopathology*, 29 (1939), No. 7, pp. 652-654, fig. 1).—The author describes the stem rot of *Lychnis viscaria* due to *P. cactorum*, which invades all the stem tissues. The fungus proved nonpathogenic on Grimes Golden apple trees, and thus differs in pathogenicity from the form of *P. cactorum* frequently isolated from apple trees and fruits in Indiana.

The effect of temperature and relative humidity on the powdery mildew of roses. K. LONGERUE ([New York] Cornell Sta. Mem. 223 (1939), pp. 43, figs. 13).—Temperature effects on germination of the pathogen (*Sphaerotheca pannosa*) were studied on spores dusted on dry slides in moist chambers and on detached leaves floating on sucrose solutions. Excellent germination was obtained on slides provided certain strictly controlled humidity conditions were maintained, and it is shown that high germination is a matter of relative humidity and not the result of something peculiar to the leaf. Spore counts after 48 hr. at 18° C. and above and after 4 days below 18° indicated 3°-5° to be the minimum, 21° the optimum, and 33° the maximum for germination. At 3°-5° and at 30°-31° haustoria occasionally developed on detached leaves, but with no further growth, while at 33°-34° none were found. At 6°-10° mycelium was scant, at 11°-23° growth was good, and at 18°-25° it was optimum. No sporulation was found below 9°-10° or above 27°-27.5°. The greatest number of spores per conidiophore occurred at 21°-27.5°, but at 27.5° the number of conidiophores was scant. High germinability was reached at first at 27°-27.5°, but at 18°-19° the period of high germinability on a given leaflet

was longest. No true stimulative effect of temperature changes on germination was found. At 0° germinability was lost after 48 hr. At 21° preservation of germinability of detached spores depended largely on the relative humidity, decreasing rapidly as this was lowered, and in general the results were similar at 33°-34°.

Dusted on slides at 21°, a relative humidity of ± 97 -99 percent gave excellent germination, at 99.8-100 percent it was somewhat lower, at 95 percent it was very low, and at 75 percent there was no germination. Dusted on leaves of rose shoots at constant temperature, germination was reduced as the atmospheric humidity decreased, but, in general, spores on leaf surfaces germinated in what appeared to be a very dry atmosphere. Germination was higher on young than on old leaves, and the under surface was slightly more favorable than the upper. It is believed that cuticular rather than stomatal transpiration is the more important factor in relative humidity at the leaf surface. The evidence indicated that relative humidity at the leaf surface, especially of young leaves, is very high even in a dry atmosphere. As to mycelium on young leaves, decreasing relative humidity resulted in sparser development and fewer conidiophores, paralleling the effect on germination. Old leaves of the susceptible *Excelsa* variety were less susceptible than young leaves, and the upper surface less so than the lower, while old leaves of the *Pernet* variety were resistant under any condition. There was some evidence that the poorer germination of spores immersed in water as compared with those floating on the surface is due at least in part to deficient oxygen.

ECONOMIC ZOOLOGY—ENTOMOLOGY

[Contributions on wildlife research and management] (*U. S. Dept. Agr., Bur. Biol. Survey, Wildlife Res. and Mangt. Leaflets BS-115* (1938), pp. 6; *BS-116*, p. 1; *BS-117*, pp. 5, pl. 1; *BS-118*, pp. 35; *BS-119*, pp. 6; *BS-120*, pp. 2; *BS-121*, pp. 6, pls. 3; *BS-122* (1939), pp. 13; *BS-123*, pp. 15, fig. 1; *BS-124*, pp. 7; *BS-125*, pp. 5; *BS-126*, pp. 7; *BS-127*, pp. [2], pls. 3; *BS-128*, pp. 2, pl. 1; *BS-129*, pp. 4; *BS-130*, pp. 3; *BS-131*, pp. 5, fig. 1; *BS-132*, pp. 5; *BS-133*, pp. 10; *BS-134*, pp. 9; *BS-135*, pp. 8; *BS-136*, pp. 18, figs. 2; *BS-137*, pp. 10, pls. 3).—Further contributions in this series (*E. S. R.*, 80, p. 365) are as follows: Cultural and Other Methods for the Control of Injurious Wildlife, by D. A. Spencer (*BS-115*); Suggestions for Control of Coccidiosis in Rabbits, by E. L. Vail (*BS-116*); Protecting Orchard Trees From Deer, by E. M. Mills (*BS-117*); Abstract of Fur Laws, 1933-39, by F. G. Grimes (*BS-118*); The Coordination of Mosquito Control With Wildlife Conservation, by C. Cottam (*BS-119*); Botulism, a Recurring Hazard to Waterfowl, With Notes on Recent Outbreaks in the United States, Canada, and Australia, by E. R. Kalmbach (*BS-120*); Two Home-Made Traps for English Sparrows (*BS-121*); Big-Game Inventory of the United States, 1937 (*BS-122*); Crow Damage to Fall Grain Crops in Oklahoma in 1937, With a Comparison of Field and Questionnaire Methods of Appraisal, by R. H. Imler and E. R. Kalmbach (*BS-123*); Factors in Nesting Losses of the California Valley Quail, by E. E. Horn (*BS-124*); Natural Plantings for Attracting Waterfowl to Marsh and Other Water Areas (*BS-125*); History and Significance of American Wildlife—II, Trends From Exploitation to Restoration, by H. life-Forest Relationships, by E. E. HORN (BS-132); A Preliminary Investigation of the Food Habits of the Mourning Dove in Alabama, by W. ROSENE, JR. (BS-133); A Summary of the Gray Squirrel Investigation in Southeastern Ohio, by F. B. CHAPMAN (BS-134); Personnel in Federal Game-Law Enforcement, by W. E. CROUCH and C. A. LEICHHARDT (BS-135); The Waterfowl Situation, 1938-39 (BS-136); and Fall and Winter Food Habits of Deer in North-eastern Minnesota, by S. E. ALDOUS and C. F. SMITH (BS-137).

The recent mammals of Idaho, W. B. DAVIS (*Caldwell: Caxton Printers, 1939, pp. 400, [pls. 2], figs. 33*).—The author recognizes 141 kinds of mammals, representing 6 orders, 20 families, and 55 genera, as found in Idaho. Fifty-seven percent of the forms recognized are rodents. Each form is treated separately as to name, type locality, distribution, diagnostic characters, and, where known, ecology. A 10-page list of references to the literature cited is included.

Distribution of mammals in the Japanese Empire, N. KUBODA (*Jour. Mammal., 20 (1939), No. 1, pp. 37-50*).—This contribution is presented with a list of 38 references to the literature cited.

A parasitological reconnaissance in Alaska with particular reference to varying hares, C. B. PHILIP (*Jour. Mammal., 20 (1939), No. 1, pp. 82-86*).—A survey made in various points of Alaska during June and July 1937, with a view to detecting the possible occurrence of Rocky Mountain spotted fever virus in the rabbit tick, is reported. In the course of the survey, 172 varying hares were taken at various places in south-central Alaska and at Lake Bennett, Canada. The greatest density of population, "judged by numbers taken per unit of sampling time, appeared to be in the vicinity of Fairbanks. Tularemia was recovered from rabbit ticks in a very limited area near Fairbanks. The general scarcity of rabbit ticks and fleas makes it difficult to see how tularemia could soon be a factor, if at all, in extensive decimation of hares, although there appeared to be near-peak abundance of these animals in most of the areas visited."

Trapping moles, J. J. WOODS (*Canada Dept. Agr. Pub. 622 (1938), pp. 4, figs. 2*).

Reactions of muskrat populations to drought, P. L. EBBERTON. (Iowa Expt. Sta.). (*Ecology, 20 (1939), No. 2, pp. 168-186*).—The author has found that "a large proportion of the muskrats resident in drying out habitats tend to stay in familiar home ranges, and, while they may suffer heavy or even annihilative mortality, they are usually more fortunate than the animals that attempt to go elsewhere. As vicissitudes become intensified, there is a conspicuous increase of intraspecific strife, vulnerability to predation (notably by mink), random and often lethal wandering, and, in winter, losses from hunger and cold."

Fall food habits of the raccoon in central Iowa, L. W. GILES. (Iowa Expt. Sta.). (*Jour. Mammal., 20 (1939), No. 1, pp. 68-70*).

Biographical sketch of Stuart T. Danforth, 1900-1938, A. WETMORE (*Jour. Agr. Univ. Puerto Rico [Col. Sta.], 23 (1939), No. 1, pp. 1-8*).—This biographical sketch includes a bibliography of the ornithological contributions by the late Dr. Danforth, largely based upon collections and observations made in the West Indies, compiled by the author and H. Friedmann.

The birds of Guadeloupe and adjacent islands, S. T. DANFORTH (*Jour. Agr. Univ. Puerto Rico [Col. Sta.], 23 (1939), No. 1, pp. 9-46*).—Of the 91 forms of birds known from the Guadeloupe and adjacent islands 88 are recorded from Guadeloupe, 2 for the first time.

The birds of Monserrat, S. T. DANFORTH (*Jour. Agr. Univ. Puerto Rico [Col. Sta.]*, 23 (1939), No. 1, pp. 47-66).—From the island of Monserrat, 11 miles long and 7 miles wide and situated about 35 miles southeast of Guadeloupe, 58 species are recorded, 14 for the first time.

Food of some uncommon North American birds, C. COTTAM and P. KNAPPEN. (U. S. D. A.). (*Auk*, 56 (1939), No. 2, pp. 138-169).—This contribution presents such data as are available in the food habits laboratory of the U. S. D. A. Bureau of Biological Survey on the food of nearly 50 uncommon, vanishing, or extinct species of North American birds, with a bibliography of 44 titles.

Foods of bob-white in Wisconsin, P. L. ERRINGTON. (Iowa State Col.). (*Auk*, 56 (1939), No. 2, pp. 170-173).—The stomach contents of 58 bobwhites (*Colinus virginianus*) that were collected in Dane, Sauk, and Columbia Counties of Wisconsin between April 4 and November 23, 1930 and 1931, are reported upon. A report of earlier studies of the foods of the bobwhite in the north-central United States made during the winter months has been noted (E. S. R., 75, p. 804).

The comparative ability of the bob-white and the ring-necked pheasant to withstand cold and hunger, P. L. ERRINGTON. (Iowa Expt. Sta.). (*Wilson Bull.*, 51 (1939), No. 1, pp. 22-37).—Field and experimental data from Iowa and Wisconsin, chiefly obtained between 1929 and 1934, are said to indicate that susceptibility to cold attending decrease in weight was usually much more pronounced in bobwhites than in ring-necked pheasants, and that the latter were also better able to retard and to endure starvation as well as to recover after temporary food crises. A list is given of 20 references to the literature cited.

The food of the giant toad (*Bufo marinus* (L.)) in Trinidad and British Guiana, with special reference to the ants, N. A. WEBER (*Ann. Ent. Soc. Amer.*, 31 (1938), No. 4, pp. 499-503).—The results of examinations of the stomach contents of 26 specimens of *B. marinus* from Trinidad and British Guiana are reported. Thirty-five ant forms and 21 animals other than ants were identified.

The animals associated with edible fungi, C. A. THOMAS. (Pa. Expt. Sta.). (*Jour. N. Y. Ent. Soc.*, 47 (1939), No. 1, pp. 11-37).—An annotated list, presented with a bibliography of seven pages.

[Notes on economic insects and their control] (*Jour. Econ. Ent.*, 32 (1939), No. 3, pp. 467-470).—The contributions presented (E. S. R., 81, p. 539) are: Corrodentia as Pests of Ground Feed, by J. Hawkins (p. 467) (Maine Expt. Sta.); Introduced Pine Sawfly [*Acantholyda erythrocephala* (L.)], by C. L. Griswold (pp. 467, 468) (U. S. D. A.); Observations on the Potato Psyllid [*Paratrioxa cockerelli* (Sulc.)] in Southwest Texas, by M. J. Janes (p. 468) (Tex. Sta.); Notes on the Biology and Control of the Greenhouse Stone Cricket [*Tachycines asymmorus* Adel.], by I. G. Bue and J. A. Munro (p. 468) (N. Dak. Agr. Col.); New Mosquito Records from Key West, Fla., by F. W. Fisk (p. 469); Cryolite Dips as a Control Measure for the Corn Root Webworm on Newly Set Tobacco Plants, by L. B. Scott and J. Milam (p. 469) (U. S. D. A.); Transmission of the Narcissus Mosaic Virus by Aphids [Bean Aphid, Potato Aphid, *Marcosiphum rosae* (L.) and *Myzus convolvuli* (Kalt.)], by F. S. Blanton and F. A. Haasis (pp. 469, 470) (U. S. D. A. and Cornell Univ.); Distances Traveled by Newly Hatched Codling Moth Larvae, by L. F. Steiner (p. 470) (U. S. D. A.); and Fixation Method for Distinguishing Dead and Live Black Scale on Citrus, by J. F. Kagy, C. O. Persing, and K. E. Maxwell (p. 470) (Calif. Citrus Sta.).

[Contributions on economic insects and insect control] (*Peninsula Hort. Soc. [Del.] Trans.*, 52 (1938), pp. 68-76, 88-98, 103-120, 136-141, fig. 1).—Contributions presented December 1938 included the following: What the Orchard Survey Disclosed in 1938, by E. N. Cory and C. Graham (pp. 68-76) (Md. Expt. Sta.); The Relation of Copper Fungicides to Lead Arsenate-Lime and Fixed Nicotine-Oil Sprays—1938 Results, by K. J. Kadow, S. L. Hopperstead, and M. W. Goodwin (pp. 88-98) (Univ. Del.); Spraying Experiences in 1938, by L. A. Stearns, D. MacCreary, and R. L. Pierpont (pp. 103-114) (Del. Sta.); and Spray Injury Studies in Maryland, by H. S. McConnell (pp. 115-117). Résumé of Japanese Beetle Retardation Work in Maryland for 1938, by G. S. Langford (pp. 118-120), and Practical Aspects of Pea Aphid Control, by L. P. Ditman (pp. 136-141) (all Md. Sta.).

Florida entomological conditions in 1938, J. R. WATSON (*Citrus Indus.*, 20 (1939), No. 2, pp. 11, 14).

[Work in economic zoology, entomology, and parasitology by the Hawaii Station] (*Hawaii Sta. Rpt.* 1938, pp. 43, 44, 75-82, 92-95, figs. 2).—Reporting for the year (E. S. R., 79, p. 502) the work referred to includes a host list of the principal crop insects of Hawaii, by F. G. Holdaway; studies on the liver fluke *Fasciola gigantica* of cattle, with the longevity of liver-fluke cysts, the development of liver fluke in the final host, the life cycle of the intermediate snail host *Fossaria ollula*, and the longevity of liver fluke in cattle, all by J. E. Alicata, effects of liver flukes on milk production and body weight of dairy cows and prenatal infection of calves with liver flukes, both by G. W. H. Goo, L. A. Henke, and S. H. Work, treatment of fluke-infected cattle with Distol and with Kamala, both by Goo and Alicata, and treatment of a heifer with extract of male fern (*Oleoresin of Aspidium*), by Goo; prevalence of parasites in swine, by Alicata; poultry parasites, including relation of nutrition to ascarid infection and life history of the tapeworm *Hymenolepis exigua*, both by Alicata and Chang, and intermediate hosts of the cecal fluke *Postharmostomum gallinum*, additional intermediate hosts for the gizzard worm *Ochetospirura hamulosa*, and parasites of pigeons in Hawaii, all by Alicata; and rodent control, including poison bait, trap, and rat migration studies, by H. J. Spencer.

[Work in entomology by the Idaho Station] (Partly coop. U. S. D. A.) (*Idaho Sta. Bul.* 229 (1939), pp. 28-30).—The work of the year reported upon (E. S. R., 80, p. 70) relates to pyrethrum dust for *Lygus* control on alfalfa seed, rotenone for control of garden insects, dust and trap crops for pea weevil control, control of insects by parasites, codling moth control, identification of spider mites, and wireworm investigations.

[Contributions on economic insects and insect control] (*Ill. State Hort. Soc. Trans.*, 72 (1938), pp. 177-197, 385-395, 501-511, figs. 4).—Contributions presented at conventions held in November 1938 and January 1939 include the following: 1938 Experiments in Codling Moth Control in the Eastern States, by W. P. Flint (pp. 177-182) (Ill. Expt. Sta. et al.); New attacks on the Plum Curculio and Peach Borer, by S. C. Chandler (pp. 182-197); Apple Leafhopper, Leafroller, and Curculio Control in Apple Orchards, by W. P. Flint (pp. 385-395) (Ill. et al.); and 1938 Results with Lead Arsenate Substitutes, by M. D. Farrar, S. C. Chandler, D. Powell, and W. P. Flint (pp. 501-511).

[Work in economic zoology and entomology by the Indiana Station] O. W. FORD, G. A. FIGHT, G. E. GOULD, G. E. MARSHALL, J. J. DAVIS, B. E. MONTGOMERY, P. LUGENBILL, E. V. WALTER, L. F. STEINER, J. E. FAHEY, and G. C. ODERKIRK. (Partly coop. U. S. D. A.). (*Indiana Sta. Rpt.* 1938, pp. 10, 50, 51, 52-58).—Reference is made (E. S. R., 79, p. 649) to work of the year with the codling moth, European corn borer, cutworms, potato insects, tarnished plant

bug, cucumber beetles, cabbage insects, oriental fruitworm and parasites, apple leafhopper, cockroaches, hessian fly, white grub, corn earworm, forest insect survey, deciduous fruit insect investigations, and rodent control.

[Work with insects by the Nebraska Station] (*Nebraska Sta. Rpt.* [1938], pp. 11, 12).—The work of the year reported upon (E. S. R., 79, p. 504) includes control of the chinch bug, hessian fly, and flatheaded apple tree borer; and grasshopper control.

[Contributions on economic insects in British Columbia] (*Ent. Soc. Brit. Columbia, Proc.*, No. 35 (1939), pp. 5-8, 11-13, 15-19, 23-30, figs. 3).—Among contributions presented (E. S. R., 80, p. 367) are the following: Insects Attacking Forest Products and Shade Trees in Washington and Oregon in 1937, by R. L. Furniss (pp. 5-8) (U. S. D. A.); A Note on Brine Flies in British Columbia (Ephydriidae: Diptera), by I. J. Ward (pp. 11-13); Ectoparasites of Deer in British Columbia, by G. J. Spencer (pp. 15-19); The Scale Insects of British Columbia, by E. P. Venables (pp. 23, 24); Some Food Plants of Lepidopterous Larvae—List No. 6, by J. R. J. Llewellyn Jones (pp. 24-27); Phenomenal Infestation of Ectoparasites on Marmot, Weasel, and Packrat, by G. P. Holland (pp. 27, 28); and Notes on the Occurrence of *Grylloblatta campodeiformis* Walker in the Kalmoops District, by J. D. Gregson (pp. 29, 30).

Report on the entomological division for the year 1937, L. D. CLEARIE (*Brit. Guiana Dept. Agr., Div. Rpts.*, 1937, pp. 83-88).—This report relates particularly to work of the year with insects affecting sugarcane and means for their control (E. S. R., 80 p. 797).

Pests and parasites, J. C. F. FRYER and H. W. MILES (*Jour. Roy. Agr. Soc. England*, 99 (1938), pp. 380-414).—Report is made on the important insect enemies of cereal, vegetable, and fruit crops and the progress of work with insecticides. A list is given of 101 references to the literature.

Observations on parasitism and superparasitism (Lepid.: Sphingidae; Hymen.: Braconidae, Chalcididae), C. B. WORTH (*Ent. News*, 50 (1939), No. 5, pp. 137-141).—In observations of parasitism at Swarthmore, Pa., the catalpa sphinx was found attacked by *Apanteles congregatus* to the extent of 83 percent in a single case. Likewise, "in a single case, larvae of *A. congregatus* were parasitized by a species of Chalcididae to the extent of 50 percent. *A. congregatus* usually lays about 60 eggs. The mortality of *A. congregatus*, before completing the reproductive cycle, is estimated at 94.3 percent. The species of Chalcididae mentioned is estimated to (1) experience a mortality twice as great as that of the braconid, or (2) lay only half as many eggs, or (3) lay half its eggs in caterpillars which have not been parasitized by braconids, or (4) be partially eliminated in some other way."

The influence of the quality of the food on the egg-production in some insects, J. K. DE JONG (*Treubia [Buitenzorg]*, 16 (1938), No. 4, pp. 445-468, figs. 4).—Report is made of experiments with *Epilachna*, *Helopeltis*, *Tinotius*, and *Diacrisia*. A list is given of 11 references to the literature.

Growth of insects with reference to progression factors for successive growth stages, F. H. HARRIES and C. F. HENDERSON. (U. S. D. A.). (*Ann. Ent. Soc. Amer.*, 31 (1938), No. 4, pp. 557-572, figs. 4).

An analysis of insect growth curves, L. C. WOODRUFF (*Jour. N. Y. Ent. Soc.*, 47 (1939), No. 1, pp. 47-55, figs. 4).

Additional observations on the sleep of insects, P. RAU (*Ann. Ent. Soc. Amer.*, 31 (1938), No. 4, pp. 540-556, figs. 9).—This contribution is presented with a bibliography of 107 titles.

The longevity of insects during complete inanition, N. S. R. MALUF (*Amer. Nat.*, 73 (1939), No. 746, pp. 280-285).

Ageing of insects, L. O. HOWARD (In *Problems of Ageing: Biological and Medical Aspects*, edited by E. V. COWDRY. Baltimore: Williams & Wilkins Co., 1939, pp. 53-70).—This discussion is accompanied by a list of 42 references to the literature.

Insect aerial populations, H. E. MCCLURE (Iowa State Col.). (*Ann. Ent. Soc. Amer.*, 31 (1938), No. 4, pp. 504-513, figs. 5).—The results of collections made daily with a net on the fender of an automobile from May 3, 1934, to May 11, 1935, in an attempt to determine the relative abundance of insects in the air at Horse Cave, Ky., and Danville, Ill., are reported.

The distribution of insects, spiders, and mites in the air, P. A. GLICK (*U. S. Dept. Agr., Tech. Bul.* 673 (1939), pp. 151, pls. 5, figs. 13).—A report is made of collections of insects in the air by means of special traps fitted to the wings of various types of airplanes during the 5-yr. period from August 1926 to October 1931. During this period the traps were in operation for 1,007 hr. in 1,314 flights around Tallulah, La., and 44 flights around Tlahualilo, Durango, Mexico. Insects and spiders to the number of 30,083 were taken at altitudes ranging from 20 to 15,000 ft. Though taken in every month of the year, they were caught most abundantly in May, with the fewest number being taken in January and December. "Eighteen orders of insects and the orders of spiders and mites were collected. There were represented in the Louisiana collections 216 families, 824 genera, 4 new genera, 700 species, and 24 new species. The order Diptera was the most abundant order in the air, and nearly three times as many specimens were taken as of any other order. Coleoptera followed next after Diptera in the numbers taken. Homoptera and Hymenoptera were taken at 14,000 ft., the highest altitude at which insects were found. The highest altitude at which any specimen was taken was 15,000 ft., at which a spider was caught. The numbers of insects taken at different altitudes in 10 min. of collecting in the daytime were as follows: At 200 ft., 13.03 specimens; 1,000 ft., 4.70; 2,000 ft., 2.41; 3,000 ft., 1.35; and 5,000 ft., 0.64 specimens. For the night collections the figures are: At 500 ft., 15.31 specimens; 1,000 ft., 5.73; 2,000 ft., 2.52; 3,000 ft., 1.11; and 5,000 ft., 0.89 specimens. . . .

"There is much evidence to support the conclusion that many of the insects taken in the upper air were alive at the time they were collected. Many specimens were alive when removed from the screens. Among the most interesting of these was 1 mosquito, *Aedes vexans*, and a cicadellid, *Graphocephala versuta*, taken alive at 5,000 ft., a coccinellid, *Coleomegilla floridana*, at 6,000 ft., an aphid at 7,000 ft., and a small dermestid larva (*Trogoderma* sp.) at 9,000 ft. . . .

"Flights made over the flooded area of 1927 at Tallulah showed definitely that fewer insects were in the air at the lower altitudes. However, the numbers taken at 1,000 ft. and above were approximately the same as over non-flooded territory, indicating that insects flew or drifted in.

"In the airplane collections of insects in Mexico the pink bollworm moth was found as high as 3,000 ft. This and other studies all indicate that the pink bollworm moths are carried in the upper air currents for considerable distances.

"Modern aircraft offer a new source of danger in the dispersal and distribution of diseases and dangerous insect pests. During the 5 yr. of flying to collect insects many insects were found in the cockpits of the planes used, even during flight."

A list is given of 79 references to the literature cited.

Insects found on aircraft at Miami, Fla., in 1938, E. V. WELCH (*Pub. Health Rpts. [U. S.]*, 54 (1939), No. 14, pp. 561-566).—A summary of insects found on aircraft arriving at Miami, Fla., from Central America, South America,

and Mexico from January 1 to December 31, 1938, is presented. It is pointed out that the inspection of all incoming aircraft from these countries, especially South America, is made primarily for the purpose of detecting the presence of live mosquitoes, particularly the yellow-fever mosquito.

Vapor-heat treatment for the control of narcissus bulb pests in the Pacific Northwest, R. LATTA (*U. S. Dept. Agr., Tech. Bul.* 672 (1939), pp. 54, figs. 34).—The development of the vapor-heat method for Mediterranean fruitfly control in Florida led to work at Sumner in the Puyallup Valley of Washington to determine the adaptability of this method for the thermal treatment of narcissus bulbs for pest control in the Pacific Northwest as an alternative to the hot-water method.

"In the experimental work it was determined that a treatment temperature of 110° to 111° F. was the most favorable. This temperature has been used as a standard in the hot-water treatment also. The minimum durations at this temperature necessary for complete mortality of the insects and mites were determined as follows: Narcissus fly 1½ hr., lesser bulb flies 1½ hr., bulb scale mite ½ hr., [and] bulb mite ½ hr. In the experimental results thus far obtained almost complete control of the bulb nematode has been produced by 8-hr. treatments at 110° to 111° during the earlier part of the storage season. When bulbs are intended for greenhouse-flower production, satisfactory results may be obtained by treating the bulbs for not more than 2 hr. at 110° to 111° for insect and mite control, during the first half of August, after at least 3 weeks of drying. Attention must be given to varietal differences in tolerance. Poetaz, poeticus, polyanthus, and tazetta types respond favorably only to early-season treatments. Bulbs intended for field planting for bulb production tolerate treatments of long duration, and the effect on flowers is not associated with the effect on bulb increase. Although the period during which treatments may be given with satisfactory results was found to be extensive, the prelim-

inary results obtained in the nematode-control studies indicate that treatment should be given soon after the bulbs are dug. For planting stocks the 8-hr. duration at 110° to 111° necessary for nematode control is desirable as a protective measure. Bulbs may be treated in consecutive seasons without fear of detrimental effects. Ceresan treatment for control of basal rot is compatible with vapor-heat treatment. When properly applied, vapor-heat treatment of planting stocks may be expected to result in vigorous growth and an above-normal increase in bulb production."

Preparation of calcium arsenates of low solubility, O. A. NELSON. (U. S. D. A.). (*Jour. Econ. Ent.*, 32 (1939), No. 3, pp. 370-372, fig. 1).—Investigations reported reveal that by proper control of conditions calcium arsenates can be prepared that are uniform in composition, basicity, and soluble As_2O_3 .

Terpene ethers in pyrethrum and rotenone fly sprays, R. L. PIERPONT (*Delaware Sta. Bul.* 217 (1939), pp. 59, figs. 18).—Following a brief introduction and description of materials report is made of toxicity tests (pp. 8-55) conducted, the details of which are given in 33 tables and 18 figures, and of physiological tests (pp. 56, 57), of ethylene glycol ether of pinene. The most effective of the various synthetic terpene ethers investigated, namely, ethylene glycol ether of pinene (D. H. S. Activator), was found to be relatively toxic to houseflies and also an effective activator for pyrethrum and rotenone in fly sprays and can be safely and economically included in commercial fly sprays. "A marked increase in the insecticidal action of solutions containing 50, 75, 100, 125, and 150 mg. pyrethrins, respectively, per 100 cc. in a petroleum oil base was obtained by the addition of 2.5, 5, 7.5, and 10 percent of D. H. S. Activator. The 'kill' was increased approximately 10 percent for each 2.5 percent of Activator added. Combinations of pyrethrum and D. H. S. Activator display the rapid, toxic action of both ingredients, there being no significant mortality after 24 hr. D. H. S. Activator reduced the 'knockdown' time of pyrethrum in sprays in relation to the amount added, that is, the more Activator, the quicker the knockdown. A straight pyrethrum fly spray (100 mg. pyrethrins per 100 cc.) in a petroleum oil base and the same spray containing various amounts of D. H. S. Activator were stored in airtight tin cans at room temperatures ranging from 70°-80° F. for a period of 22 mo. without any loss in toxicity or reduction in the activation effect. . . . The insecticidal action of solutions containing 50 and 100 mg. rotenone, respectively, per 100 cc. and 7.5 percent safrole in a petroleum oil base was also increased by the addition of 2.5, 5, 7.5, and 10 percent of D. H. S. Activator. The increases were less than with pyrethrum fly sprays, approximating 5 percent for each 2.5 percent of Activator added. The 24-hr. mortality for rotenone fly sprays was increased by the addition of D. H. S. Activator without any significant reduction in the 24- to 48-hr. mortality characteristic of them. As with pyrethrum fly sprays, D. H. S. Activator reduced the knockdown time of the rotenone-safrole combinations in relation to the amount added, that is, the more Activator the quicker the knock-down."

Studies with dinitro-o-cyclohexylphenol, A. M. BORCE, J. F. KAGY, C. O. PERSING, and J. W. HANSEN. (Calif. Citrus Expt. Sta.). (*Jour. Econ. Ent.*, 32 (1939), No. 3, pp. 432-450, figs. 3).—Studies of dinitro-o-cyclohexylphenol, which has been used in insecticide investigations in California since 1935, and particularly certain of its physical and chemical properties that may concern its use on citrus and certain other plants, are reported. "A satisfactory colorimetric method of analysis has been developed. The solubility of the dinitro-o-cyclohexylphenol in various organic solvents, including petroleum spray oils, and in water has been determined. The solubility of the compound in

water increases with a rise in pH. The distribution of the compound between the oil and aqueous phases of spray emulsions has been investigated. In acidified emulsions (pH 3.5 to 5.0) over 90 percent of the compound remains in the oil phase at equilibrium. In alkaline waters (pH 8.0 to 11.0) less than 5.0 percent of the compound remains in the oil phase. The phase distribution of dinitro-*o*-cyclohexylphenol greatly affects the toxicity of emulsions containing this compound to the eggs of the citrus red mite (*Paratetranychus citri* (McG.)) and to the eggs of the plant bug *Lygaeus kalmii* Stal. Field investigations have shown that certain oil emulsions containing dinitro-*o*-cyclohexylphenol are effective in the control of the black scale (*Saissetia oleae* (Bern.)), the citricola scale (*Coccus pseudomagnoliarum* (Kuw.)), the citrus red mite (*P. citri*), the citrus whitefly (*Dialeurodes citri* Ashm.), the European elm scale (*Gossyparia spuria* (Mod.)), the walnut scale (*Aspidiotus juglans-regiae* Comst.), and the frosted scale *Lecanium prunosum* Coq.

"An investigation concerned with the use on citrus of dinitro-*o*-cyclohexylphenol in certain water-insoluble organic solvents other than petroleum oil has shown that emulsions of these solutions are appreciably toxic to the black scale. Tree-tolerance experiments showed that there was a direct relation between the boiling point of the solvent and the degree of injury resulting from these spray mixtures on citrus. The effectiveness of aqueous solutions of dinitro-*o*-cyclohexylphenol for the control of the black scale on citrus has been investigated during the last 2 yr. In this connection the sodium and triethanolamine salts have offered promise. Physical properties and methods of preparation of these salts as related to field usage have been studied. Field results indicate that aqueous sprays containing 0.085 percent dinitro-*o*-cyclohexylphenol in solution as the sodium or triethanolamine salt will afford satisfactory control of the black scale on citrus. Colloidal dispersions of this compound prepared and used in several ways have afforded high mortalities of the black scale and of eggs of the citrus red mite. A dust mixture which contains 1 percent of this compound incorporated in either walnut-shell flour or redwood-bark flour has proved to be an effective acaricide for the control of the citrus red mite on citrus and the common red spider (*Tetranychus telarius* (L.)) on Persian walnuts. Experiments on the control of the orange tortrix (*Argyrotaenia citrana* (Fern.)), the citrus thrips (*Scirtothrips citri* (Moul.)), the greenhouse thrips (*Heliothrips haemorrhoidalis* (Bouché)), and red scale *Aonidiella aurantii* (Mask.), have shown that the compound is toxic to these insects, but for various reasons its use is not likely to be practical under field conditions. Considerable attention has been directed to the phytocidal action of this compound when applied to citrus and other plants under a wide range of meteorological conditions in various insecticidal combinations. Although dinitro-*o*-cyclohexylphenol may cause injury to citrus and other subtropical plants under certain conditions, the indications are that it can be used with comparative safety on these plants, especially in dust mixtures and possibly in aqueous dispersions. The relation of dinitro-*o*-cyclohexylphenol to public health has been considered. Available evidence does not indicate the existence of a problem in this regard."

Dinitro-*o*-cyclohexylphenol in the control of mites on citrus and Persian walnuts, A. M. BOYCE, D. T. PRENDERGAST, J. F. KAGY, and J. W. HANSEN. (Calif. Citrus Expt. Sta.). (*Jour. Econ. Ent.*, 32 (1939), No. 3, pp. 450-467, figs. 6).—Work on the chemical control of mites, conducted in connection with that above noted, is reported, the details being given in tables and charts. In field work in 1937 "a properly prepared solvent-mix dust consisting of 1 percent dinitro-*o*-cyclohexylphenol in walnut-shell flour gave promising results for control of the citrus red mite. . . . A proprietary product registered in California

as DN Dust was made available for limited commercial usage in April 1938. Over 1 million pounds have been applied commercially by the manufacturer under a wide variety of conditions. Improved dusting equipment was devised to insure more thorough application of dust insecticides on citrus. The dosage of DN Dust for a mature tree varies in accordance with the presence of fruits that are approximately one-half of full size or larger, the presence of moisture on the trees at the time of application, and the density of tree foliage. A dosage of 1 lb. of DN Dust per tree when only young fruit is present appears adequate under most conditions. In the presence of larger fruit the dosage must be increased to 1.5 or 2 lb. per tree. If moisture is present at the time of application, this dosage may be reduced by approximately 25 percent. When the foliage is less dense, particularly in the case of lemons, the dosage must be increased. A program consisting of two properly synchronized applications is most dependable in effecting control, although one application has, in some localities, afforded very satisfactory control for periods of several months and longer.

"It has been found that DN Dust can be used with comparative safety on citrus. The most important factor relating to injury appears to be the incidence of high temperatures occurring within a period of 2 days after application. By not applying the DN Dust when temperatures above 95° F. are forecast, this injury has been of negligible economic importance. . . . DN Dust has been used on peaches and almonds infested with common red spider and the clover mite (*Bryobia praetiosa* Koch), high mortalities having been obtained in all instances. No injury to the trees has been observed. . . . There appears to be no significant public health hazard involved in the use of this preparation either to the operators who apply the dust or to the consumers of treated fruits."

Agar-agar, a new activator for nicotine sprays, S. S. SHARP. (La. Expt. Sta.). (*Jour. Econ. Ent.*, 32 (1939), No. 3, pp. 394, 395).—In experiments with the pea aphid it was shown that "agar-agar trebled the effectiveness of nicotine sprays on the pea aphid. The activation by agar-agar was equal to that produced by karaya gum. Both agar-agar and karaya gum are difficult to disperse in water and are unsatisfactory for general use in sprays. The dispersal of karaya gum is materially assisted by the use of alcohol and light mineral oils, whereas agar-agar is best dispersed by boiling in water."

Fluorine spray residue removal with dilute solutions of hydrochloric acid, boric acid, and sodium chloride, E. H. KARR (*Jour. Econ. Ent.*, 32 (1939), No. 3, pp. 423-430, figs. 2).—In work reported it was found that in the removal of "fluorine spray residues from apples with a single process, overhead flood-type fruit washer, the presence of 2 percent boric acid in a 1.5 percent solution of hydrochloric acid at a temperature of 100° F. was only slightly, if at all, more effective than the hydrochloric acid solution alone. The effectiveness of a 1.5 percent solution of hydrochloric acid containing 2 percent boric acid was reduced considerably by the presence of 1 percent sodium chloride at a solution temperature of 100°. When the temperature of the hydrochloric-boric acid solution containing 1 percent sodium chloride was increased to 110°, the depressing action of the sodium chloride was prevented."

Effect of insect residues and other factors on removal of spray residues from apples, H. C. MCLEAN and A. L. WEBER. (N. J. Expt. Stas.). (*Jour. Econ. Ent.*, 32 (1939), No. 3, pp. 357-360).—In many New Jersey orchards residue removal has been frequently found to be more difficult from certain apples than from others, even though the fruit had been similarly sprayed and contained equal amounts of residue. Two important factors are responsible for these variations—(1) insect residues and (2) differences in the conditions of the foliage on the trees. Another factor influencing removal of spray residues is the

sticker and spreader used in the spray mixtures, especially when an oil plus lead arsenate spray schedule is followed. Investigations in a number of orchards have shown that fungus growth occurring on the honeydew secreted by insects, especially leafhoppers, caused difficulty in the removal of lead residues from apples. For a given spray treatment the apples from trees with heavy, luxuriant foliage were much easier to wash than those from trees with light foliage. "The spreader and sticker employed with lead arsenate, especially in summer oil spray mixtures, have an important influence on the spray residue removal from the picked fruit. Of several materials compared as to their relative effects on deposits and retention of lead arsenate, as well as their influence on removal of residues, Orthex had the desirable qualities of producing a heavy coating and of being removed without difficulty in washing."

Psocids in dwellings, E. A. BACK. (U. S. D. A.). (*Jour. Econ. Ent.*, 32 (1939), No. 3, pp. 419-423).—A practical summary, including notes from correspondence relating to psocids in various parts of the country.

The biology of the American cockroach, G. E. GOULD and H. O. DEAY. (Ind. Expt. Sta.). (*Ann. Ent. Soc. Amer.*, 31 (1938), No. 4, pp. 489-498, fig. 1).—Observations made under ordinary room conditions, which extended over a 3-yr. period, are reported.

Painting for determination of grasshopper flights, H. B. WILLIS (*Jour. Econ. Ent.*, 32 (1939), No. 3, pp. 401-403).—Trials to determine the migratory habits, including the direction, distance, and time of flights, of *Diosotera longipennis* (Thos.) and *Melanoplus mexicanus* (Sauss.), first carried on with *D. longipennis* in Colorado in 1937 and with *M. mexicanus* in Montana in 1938, are reported. A lacquer paint which had additional amyl acetate added at the rate of four parts to one of paint used was found to be satisfactory in marking grasshoppers without injuring them or retarding their flight movement. It is concluded that there are definite directions of flights of these species, and that "these directions, distances, and times involved for covering these distances can be determined by painting large numbers of grasshoppers in their hatching grounds and following their migrations through tracing the captured specimens."

The white fungus disease (*Beauveria bassiana*) among red locusts in South Africa and some observations on the grey fungus disease (*Empusa grylli*), E. E. SCHAEFER (*Union So. Africa [Dept. Agr. and Forestry]*, *Sci. Bul.* 160 (1936), pp. 28, pls. 11).—A report of work with two important entomogenous fungi.

Two new Thysanoptera from Florida, J. R. WATSON and J. R. PREER. (Fla. Expt. Sta.). (*Fla. Ent.*, 22 (1939), No. 1, pp. 1-5, figs. 2).—*Sophiothrips bicolor* and *Eurythrips robustisetis*, both from dead leaves under live oaks, are described as new.

Thysanoptera from northern New Jersey, with descriptions of new species, J. C. CRAWFORD. (U. S. D. A.). (*Jour. N. Y. Ent. Soc.*, 47 (1939), No. 1, pp. 69-81).—A list given of 71 forms of thrips known to occur in New Jersey is followed by descriptions of 4 new species.

Notes on some thrips collected in the vicinity of Babylon, Long Island, N. Y., F. S. BLANTON. (U. S. D. A.). (*Jour. N. Y. Ent. Soc.*, 47 (1939), No. 1, pp. 83-94).—Species collected near Babylon during the course of investigations of the spread of a virus disease of narcissus are noted.

Notes on pamera populations on various types of plant communities in the vicinity of Plant City, J. W. WILSON (*Fla. Ent.*, 21 (1938), No. 2, pp. 28-30).—Notes are presented on three species of lygaeids, namely, *Orthaea longulus* (Dallas), *O. vineta* (Say), and *O. bilobata* (Say), found on strawberry plants and

other vegetation that forms a heavy growth near the ground in the strawberry-growing section near Plant City, Fla. Of the three species, *O. bilobata* was by far the most abundant.

Biological notes on *Blissus iowensis* Andre (Hemiptera—Lygaeidae). G. C. DECKER and F. ANDRE. (Iowa Expt. Sta.). (*Ann. Ent. Soc. Amer.*, 31 (1938), No. 4, pp. 457-466, figs. 2).—It is concluded that since *B. iowensis* feeds largely upon a wild grass (*Andropogon scoparius*), which is no longer abundant or of great economic value, the species is not likely to assume a position of economic importance.

The use of heavy naphtha in bed-bug disinfestation. B. T. J. GLOVER (*Jour. Roy. Sanit. Inst.*, 59 (1939), No. 11, pp. 671-682).—Commercial heavy naphtha was found to be effective in the eradication of bedbugs from empty dwelling houses, a second application having been necessary in but 6 out of 1,491 dwellings thus treated for the destruction of the eggs and the adults.

A new froghopper pest of sugar-cane. A. PICKLES (*Trop. Agr. [Trinidad]*, 16 (1939), No. 4, p. 84).—A severe outbreak of the froghopper *Tomaspsis guppyi* in Trinidad in January 1939 is reported. Its injury was quite severe on Co. 213 cane, which is generally resistant to attack by the common froghopper.

Three new species of psyllids and the description of the allotype of *Livia opaqua* Cald. (Homoptera: Psyllidae). J. S. CALDWELL. (Ohio State Univ.). (*Ann. Ent. Soc. Amer.*, 31 (1938), No. 4, pp. 442-444, fig. 1).

The toxicity of derris to larvae of the citrus whitefly. L. L. ENGLISH. (Ala. Expt. Sta.). (*Jour. Econ. Ent.*, 32 (1939), No. 3, pp. 360-363, figs. 6).—In the experiments reported, dilute oil emulsions were shown to be effective supplements for derris applied against larvae of the citrus whitefly. "The efficiency of the emulsions for this purpose varied greatly with the emulsifying agent used. With an 83 viscosity oil, powdered skim milk produced a more effective emulsion than diglycol laurate, but a greater proportion of the kill obtained with the skim milk emulsion was due to the oil itself, rather than to the derris. An experiment with extracted and unextracted derris showed that derris was a true toxic agent to citrus whitefly larvae. The data also indicated that derris may be physically antagonistic to the insecticidal action of dilute emulsions."

A further contribution to the ecology of *Aleurodes brassicae* Walk. (Hemiptera). C. G. BUTLER (*Roy. Ent. Soc. London, Proc., Ser. A*, 13 (1938), No. 10-12, pp. 161-172, fig. 1).—A contribution mainly concerned with the relationship of *A. brassicae* and the physical factors of its environment.

Food-plant catalogue of the aphids of the world, including the Phylloxeridae. E. M. PATCH (*Maine Sta. Bul.* 393 (1938), pp. 35-431).—This is a compilation from aphid literature of the known food plants of Aphididae of the world. The aphid forms appear under the plant families in alphabetical order, each followed by a reference to the literature and the host species. The food plant catalog includes a bibliography (pp. 266-320), an index to plant families (pp. 321-327), and an index to aphids (pp. 329-430).

The digestive system of *Macrosiphum solanifolii* (Ash.) (Aphidae: Homoptera). C. F. SMITH. (Ohio State Univ.). (*Ohio Jour. Sci.*, 59 (1939), No. 1, pp. 57-59, figs. 4).—A study of the internal anatomy of this aphid.

Studies on pea aphid control. L. P. DITMAN. (Univ. Md.). (*Canning Trade*, 61 (1939), No. 40, p. 7).—A brief report is made of the progress of a 5-yr. experiment, commenced in 1933 at Ridgely, Md., primarily to determine the extent of pea aphid infestations on the Eastern Shore and the practicability of annual treatment for the insect.

Aphids of the genus *Kakimia* infesting ribes (Homoptera). G. F. KNOWLTON and M. W. ALLEN. (Utah Expt. Sta.). (*Ent. News*, 50 (1939), No. 6, pp.

166-170, figs. 2).—Seven species of the aphid genus *Kakimia* H. and F. that attack currants and gooseberries, one of which, *K. muesebecki*, from Redwood Canyon, Calif., is new to science, are considered.

Distribution of intermediate-winged aphids in the family and its bearing on the mode of their production, A. F. SHULL (Univ. Mich.). (*Amer. Nat.*, 73 (1939), No. 746, pp. 256-269, figs. 2).

Spraying woodlands with an autogiro for control of the gypsy moth, S. F. PORTS (U. S. D. A.). (*Jour. Econ. Ent.*, 32 (1939), No. 3, pp. 381-387, figs. 5).—This contribution is based upon spraying experiments with an autogiro at Freetown, Mass., in 1936 in control of the gypsy moth, the data being given in table form. The work "demonstrated the possibility of using this type of aircraft for the control of certain leaf-eating forest insects where the contour and regularity of the land is favorable."

The sources of *Ephestia* infestation of stored cacao in Ceylon, M. FERNANDO (*Trop. Agr. [Ceylon]*, 92 (1939), No. 3, pp. 141-155).—Report is made of methods employed and results obtained in an investigation of the sources of *Ephestia* infestation of stored cacao in Ceylon.

Larva of *Ephestia kuehniella* [kuehniella] in the egg of a hen, F. R. BEAUMITE (N. J. Expt. Stas.). (*Indian Vet. Jour.*, 15 (1939), No. 4, p. 365).

Cankerworms, T. H. JONES (U. S. Dept. Agr. Leaflet 183 (1939), pp. 8, figs. 5).—A practical account.

The cherry casebearer (*Coleophora pruniella* Clem.) in Oregon, T. Y. HSIAO and D. C. MOTE (Oreg. State Col.). (*Jour. Econ. Ent.*, 32 (1939), No. 3, pp. 363-365).—A brief account of the cherry casebearer, first discovered in Oregon in the spring of 1937, since which time it has become the source of rather heavy damage in apple orchards near Salem. In the course of cage observations the two hymenopterous parasites *Eurydinota holdicorpus* Gir. and *Microbracon pygmaeus* (Prov.) were reared.

The tomato leaf miner and its control, M. COHEN (*Jour. Min. Agr. [Gt. Brit.]*, 45 (1938), No. 5, pp. 460-462, pl. 1).—A brief account is given of observations made in 1937 of *Liomyza solani*, Macq., which first appeared in British greenhouses in 1926, as reported by E. R. Speyer,⁴ and is causing some injury to tomatoes in the British Isles.

The metabolism of the corn ear worm.—II, Glycogen and moisture, L. P. DETMAN and G. S. WEILAND (Univ. Md.). (*Ann. Ent. Soc. Amer.*, 31 (1938), No. 4, pp. 578-587, figs. 6).—A continuation (E. S. R., 79, p. 510).

The effects of neutral copper fungicides on tank-mix nicotine-bentonite in control of the codling moth, L. F. STEINER and J. E. FAHEY (U. S. D. A.). (*Jour. Econ. Ent.*, 32 (1939), No. 3, pp. 365-369, fig. 1).—Of five neutral copper compounds tested in the Midwest where they are necessary for the control of certain apple diseases, each reduced the resistance of nicotine deposits to the weathering effects of heavy rains and also reduced the effectiveness of "tank-mix-nicotine-bentonite in codling moth control. There was also evidence that at least one substantially depressed the toxicity of the nicotine deposit. All five copper compounds produced very serious foliage injury, and two used early in the season caused severe russetting and cracking of Grimes fruit. Foliage injury from copper, however, was also produced in 1938 by applications of $\frac{3}{4}$ -1½-100 Bordeaux mixture with lead arsenate."

Distribution of codling moth worms on apple trees as influenced by banding, A. M. WOODSME (Va. Expt. Sta.). (*Va. Fruit*, 27 (1939), No. 3, pp. 22, 24, fig. 1).—It was found in 1938 upon removal of codling moth bands from

⁴ Expt. and Res. Sta., Cheshunt, Herts, Ann. Rpt., 23 (1936), p. 70.

apple trees in a heavily infested orchard near Staunton that about 70 percent of the worms cocooned on banded apple trees cocooned in the bands. More than 50 percent of the worms on the branches were in pruning wounds and in cracks in dead wood. Splintered stumps of broken branches harbored many of these. In a tree on which 321 worms and cocoons were found, more than 200 were in pruning scars and stumps of broken branches. The indication that about three-fourths of the worms on the older trees are to be found on the branches emphasizes the importance of scraping those parts as a control measure.

Trapping codling moth larvae with treated corrugated paper bands, A. M. WOODSIDE. (Va. Expt. Sta.). (*Better Fruit*, 33 (1939), No. 11, pp. 3, 8, 14, 15, fig. 1).

Relation of number of European corn borers per infested corn plant to percentage of plants infested, L. H. PATCH. (U. S. D. A.). (*Jour. Econ. Ent.*, 32 (1939), No. 3, pp. 387-393, fig. 1).—Data presented give the estimated numbers of European corn borer larvae per infested cornstalk in fields of dent corn surveyed in each of the annual State surveys to determine the abundance of the borer in Ohio, Michigan, and New York from 1926 to 1936, inclusive. "When 2 percent of the stalks were infested the number of borers per infested stalk ranged from 0.8 to 2.2 and averaged 1.34. Comparable data when 25 and 62 percent of the stalks were infested showed that the numbers of borers ranged from 1.17 to 2.80 and from 1.7 to 3.9 and averaged 1.89 and 2.81, respectively."

A contribution to the knowledge of the mosquitoes of Owens Valley, Inyo County, Calif., T. H. G. ATKEN. (Univ. Calif.). (*Jour. Econ. Ent.*, 32 (1939), No. 3, pp. 407-412).—This contribution relates to observations on seven species present or approximately in Owens Valley, namely, *Anopheles maculipennis* Meig., *A. punctipennis* (Say), *A. pseudopunctipennis* Theob., *Theobaldia inornata* (Will.), *T. macrackenae* (Dyar & Knab), *Culex tarsalis* Coq., and *Aedes dorsalis* (Meig.).

A design of flushing siphon for control of anopheline breeding, G. MACDONALD (*Jour. Malaria Inst. India*, 2 (1939), No. 1, pp. 63-69, pls. 4, fig. 1).—A description is given of the design of a flushing siphon, used in control of anopheline breeding, which gives an automatic discharge of 475 gal. of water a minute.

The effect of certain chemicals on the hatching of mosquito eggs, C. M. GJULLIN, W. W. YATES, and H. H. STAGE. (U. S. D. A.). (*Science*, 89 (1939), No. 2319, pp. 539, 540).—The authors' findings indicate that the amino acids and proteins present in vegetation may be the stimulants which cause the hatching of mosquito eggs when flooded in nature.

New Jersey Mosquito Extermination Association, twenty-fifth annual meeting (*N. J. Mosquito Extermin. Assoc. Proc.*, 25 (1938), pp. 11-48, 51-57, 79-100, 106-197, 209-232, pls. 7, figs. 4).—Contributions presented at the annual meeting of the association held at Atlantic City in March 1938 (*E. S. R.*, 79, p. 367) include the following: Summary of Mosquito Control Work in New Jersey in 1937, by T. D. Mulhern (pp. 11-48) (N. J. Expt. Stas.); Comparison of Mosquito Repellency Tests Under Laboratory and Field Conditions, by P. Granett (pp. 51-57) (Rutgers Univ.); Review of Advances in Practical Methods of Mosquito Control, by F. A. Relley and R. L. Vannote (pp. 79-84); Review of Advances in Scientific Mosquito Knowledge, by J. G. Lipman (pp. 84-88), and Review of Economic Results of Mosquito Control, Work Accomplished, [and] Benefits Derived From the Mosquito Association, by T. J. Headlee (pp. 88-100) (both N. J. Stas.); New Developments in Mosquito Control in Connecticut, by R. C. Botsford (pp. 106-108) (Conn. [New Haven] Sta.), in Rhode Island, by M. H. Price (pp. 111-115), in Delaware County,

Pa., by R. L. Mentzer (pp. 125-130), and in Delaware, by W. S. Corkran (pp. 130-137); Mosquito Control in Massachusetts During 1937, by G. R. Stratton (pp. 108-111), in Greater New York, by S. Pincus (pp. 115-121), in Suffolk County, N. Y., by B. M. Mitchell (pp. 121-124), and in the Pacific Northwest, by H. H. Stage (pp. 188-197) (U. S. D. A.); Data Compiled for Mosquito Work in Virginia, by R. E. Dorer (pp. 137-139); Mosquito Control as Related to Marsh Conservation, by J. L. Clarke (pp. 139-147); Economic Importance of Malaria Control, by L. L. Williams, Jr. (pp. 148-152); A Review of Mosquito Work Throughout the World in 1937, by F. C. Bishopp and J. L. Webb (pp. 152-176) (U. S. D. A.); Mosquito Suppression Work in Canada in 1937, by A. Gibson (pp. 176-185); Problems of Mosquito Control in the Passaic Valley, by A. R. Cullimore and R. L. Vannote (pp. 185-188); Factors Affecting the Vegetative Cover of Delaware Marshes, by F. C. Daigh, D. MacCreary, and L. A. Stearns (pp. 209-216) (Del. Sta.); The Coordination of Mosquito Control with Wildlife Conservation, by C. Cottam (pp. 217-227) (U. S. D. A.); and Heartworm in Dogs—A Mosquito-Borne Menace in New Jersey, by T. C. Nelson and M. L. Morris (pp. 227-232) (Rutgers Univ. et al.).

Report of the Suffolk County Mosquito Extermination Commission, L. W. RULAND ET AL. (Riverhead, N. Y.: Suffolk Co. Mosquito Extermin. Comm., 1938, pp. 31, [figs. 10]).—A report of control work with mosquitoes in Suffolk County, Long Island, N. Y.

Ammonium sulphate as a combined fertilizer and mosquito larvicide, C. J. H. BRINK and D. K. DAS CHOWDHURY (*Jour. Malaria Inst. India*, 2 (1939), No. 1, pp. 111, 112).—Experiments conducted led to the general conclusion that while solutions of ammonium sulfate in strengths of 0.75 percent and over will prevent mosquito breeding, the recurring cost of the method renders it unsuitable for use in large irrigation areas.

A new gall midge on rhododendron, E. P. FELT (*Jour. N. Y. Ent. Soc.*, 47 (1939), No. 1, pp. 41, 42).—Under the name *Giardomyia rhododendri* a description is given of a new gall midge reared by the New Jersey Experiment Stations from larvae commonly infesting the young tips of rhododendron in a nursery at Huntington Station, Long Island, N. Y.

A new juniper midge (Diptera: Cecidomyiidae), E. P. FELT (*Ent. News*, 50 (1939), No. 6, pp. 159, 160).—Under the name of *Oontarima juniperina*, the author describes a new species which caused serious injury to juniper twigs in the Midwest during the summer of 1938.

On flies as intermediate hosts of *Syngamus trachea*, P. A. CLAPHAM (*Jour. Helminthol.*, 17 (1939), No. 2, pp. 61-64).—Flies, including the housefly and the sheep blowfly *Lucilia sericata*, reared from larvae that had ingested rabbit flesh infected with gapeworm eggs, were fed both as grown larvae and as adults to chickens that were 6 days old. "When samples from each group were dissected, it was found that the eggs had been taken up and were still alive. The larvae had found their way to the fat body surrounding the gut where they were lying loosely coiled apparently without any cyst. This condition contrasts with that found in the earthworm where a cyst is developed, but is probably due to the short time which elapsed between infection and examination, as the cyst is almost certainly produced by the host and not by the parasite. The vitality of the maggot did not appear to be impaired by the presence of the parasite, but infected adult flies tended to be somewhat sluggish and would normally be easy prey for birds in the natural state. Of 12 maggots and 12 flies so examined, all the maggots were infected, each with a single larva and 10 of the flies each again with a single larva. Feeding experiments to 12 chickens showed that most of the unexamined larvae and

imagines must also have been infected, for of 6 birds fed 20 maggots each, all developed 'gapes'—the number of pairs recovered post mortem being 1, 3, 4, 4, 4, and 8. Of the half-dozen birds fed on 20 flies each, 5 became infected, there being 2, 3, 5, 5, and 7 pairs, respectively, in the tracheae. The experiments described above are only preliminary and the beginning of a large scale group, but they prove definitely that some flies both in the larval and in the imaginal states may act as intermediate hosts for *S. trachea*. The *Syngamus* larva can apparently withstand the physical and physiological changes which accompany metamorphosis and still remain infective to chickens."

It is suggested that since many kinds of invertebrates must ingest the ova accidentally with their food, some may be ingested by wild birds with earthworms feeding mainly on pasture and woodland and become infected with a strain of gapeworm that can only complete its life cycle by means of an annelid. "Other birds in a more domestic environment which have easy access to dung, with its abundant insect fauna, will come to be definitive host to a strain of the same species needing an arthropod vector. It is quite likely that in the course of many generations the present species *S. trachea* will develop into a number of new varieties or even species each with their own individual vectors. A number of intermediate hosts which have been added accidentally to its economy may thus provide conditions favorable to the evolution of distinct species in different definitive hosts."

Empusa infections of the house-fly in relation to moisture conditions of northern Idaho, C. C. YEAGER. (Univ. Idaho). (*Mycologia*, 31 (1939), No. 2, pp. 154-156).—It is concluded that the prevalence of *E. muscae* infections of the housefly vary directly with the amount of rainfall.

Housefly control, F. C. BISHOPP (U. S. Dept. Agr. Leaflet 182 (1939), pp. 6, figs. 5).—A practical account.

Observations on the bionomics of the ox warble-fly (*Hypoderma lineatum* DeVillers), B. N. SONI (*Indian Jour. Vet. Sci. and Anim. Husband.*, 8 (1938), No. 4, pp. 375-380, figs. 3).—Over 50 percent of the hill bulls purchased for experimental purposes were infested with warble grubs (*H. lineatum*). Nearly 51 days were required for the larvae to mature after their first appearance in the subcutaneous tissues of the animal's back.

Speed of *Cephenemyia*, C. H. T. TOWNSEND (*Jour. N. Y. Ent. Soc.*, 47 (1939), No. 1, pp. 43-46).—A discussion of the speed of male deer botflies of the tentatively determined species *C. pratti*.

Volatile oils as ovicides for the screwworm (*Cochliomyia americana* C. & P.), R. C. BUSELAND. (U. S. D. A.). (*Jour. Econ. Ent.*, 32 (1939), No. 3, pp. 430, 431).—Tests were made of 37 volatile oils as ovicides for the screwworm, the eggs of this fly being divided into two classes according to age. "Oils of anise, bitter almond, cassia, fennel seed, mustard, parsley, pennyroyal, rue, saffron, and sweet birch killed all eggs in the two classes. Oils of caraway seed, clove, and lemon grass, although they did not entirely prevent hatching of the older eggs, caused the larvae to die almost immediately after hatching. The younger eggs were more easily destroyed than the older eggs, for in addition to all the oils mentioned above, oils of bay, bergamot, cajuput, citronella, coriander, cumin seed, lavender, lemon, peppermint, pine needle, rosemary, savin, spearmint, sweet orange, verbena, and wormwood were completely effective against the younger eggs."

The Amazon fly *Metagonistylum minense* Towns. in British Guiana, L. D. CLEARE (*Bul. Ent. Res.*, 30 (1939), No. 1, pp. 85-102, fig. 1).—This report deals with the work undertaken in British Guiana, including the receipt from Brazil of the tachinid parasite *M. minense* (known as the Amazon fly), its rearing

from the initial shipments, and the subsequent rearing of large numbers for the colonization of the sugar estates of the colony, which extended over the period from September 1933 to April 1935. The work reported includes its bionomics, species of *Diatraea* attacked, colonization in British Guiana, cost of introduction, parasitism of *D. saccharalis* in rice and other host plants, status in 1937, and shipments of the parasite to the West Indies. A list of 19 references to the literature is included.

Note on Paratheresia introduction in Louisiana, C. H. T. TOWNSEND (*Jour. N. Y. Ent. Soc.*, 47 (1939), No. 1, p. 38).—Brief reference is made to the introduction of sugarcane borer parasites of the genus *Paratheresia* in Louisiana, not of the genus *Theresia* as previously reported (*El. S. R.*, 80, p. 366).

Dexia rustica Fabr., a parasite of the cockchafer *Melolontha vulgaris* in Denmark [trans. title], P. BOVIER and N. BOLWIE (*Tidsskr. Planteavl*, 48 (1939), No. 5, pp. 801-818, figs. 11; *Eng. abs.*, pp. 816, 817).—The parasitism of white grubs by *D. rustica* in Denmark was found to vary from 0 to about 50 percent. The grubs are attacked during the autumn of the year following hatching, with the highest parasitism occurring in the third and fourth years.

A review of the muscoid genus *Eumacronychia*, with key and descriptions of new species (Diptera), H. J. REINHARD. (*Tex. Expt. Sta.*). (*Jour. N. Y. Ent. Soc.*, 47 (1939), No. 1, pp. 57-68).—Thirteen species of the tachinid genus *Eumacronychia* are recognized, of which 6 are described as new to science.

Sarcophaga aldrichi Parker as a parasite of *Malacosoma disstria* Hbn., A. C. HODSON. (*Minn. Expt. Sta.*). (*Jour. Econ. Ent.*, 32 (1939), No. 3, pp. 396-401, figs. 4).—Field observations and cocoon examinations have demonstrated that the dipterous parasite *S. aldrichi* attacks the forest tent caterpillar at a time when the caterpillars are constructing their cocoons and pupating. "The life cycle of the parasite is adjusted in such a manner that the flies are ready to larviposit when the first cocoons appear in the field. They produce only one generation a year because of a long period of dormancy after leaving the host. They attack perfectly normal larvae and pupae in their cocoons and are not limited to parasitized or diseased hosts. *S. aldrichi* enters into direct competition with the other parasites and destroys them when they chance to occur in the same host. This species will breed in carrion, mashed caterpillars, and other organic material. From the above evidence it may be classed as a facultative parasite which is bridging the ground between a specialized parasite and an exclusive scavenger."

Poison bait checks cherry fruit fly, S. C. JONES. (*Oreg. State Col.*). (*Better Fruit*, 33 (1939), No. 10, p. 6).—A poisoned bait spray consisting of 0.5 lb. of lead arsenate, 2 qt. of molasses, and water to make 10 gal. has been found effective in combating the white-banded cherry fruitfly in Oregon. "Since the fly spends approximately 10 days feeding on liquid substances on the foliage before laying eggs, the first spray is recommended as soon as the flies begin to emerge to kill early emerging flies before they lay their eggs. . . . Three sprays are usually sufficient to control the fly if no rains occur. The spray should be applied at weekly intervals dating from the time the first spray was applied. Rains will dissipate the spray, and the application should be repeated."

Two new species of *Agromyza* from South America (Dipt.: *Agromyzidae*), S. W. FROST. (*Pa. State Col.*). (*Ent. News*, 50 (1939), No. 4, pp. 97-100).—*A. braziliensis* from São Paulo, Brazil, and *A. ecuadorensis* from Baños, Ecuador, are described as new.

The reaction of the orange fruit to the autumn attack of the Mediterranean fruit fly and its economic status, E. RIVNAY, M. NADEL, and F. LITTAUER (*Hadar*, 11 (1938), No. 11, pp. 317, 318, 321-323, fig. 1).—A report contributed from the agricultural research station at Rehovoth.

Hippoboscid flies from North American doves, J. BEQUAERT (*Science*, 89 (1939), No. 2308, pp. 267, 268).—It is concluded that *Microlychnia pusilla*, which has been found by H. de Beaurepaire-Aragão⁵ to transmit *Haemoproteus columbae* from pigeon to pigeon in Brazil, is the most likely natural vector of dove *Haemoproteus*.

Survival of the tropical rat flea in United States, R. L. ROUDABUSH (*Science*, 89 (1939), No. 2300, pp. 79, 80).—A discussion of the occurrence and probable survival of the oriental rat flea in several of the northern States.

Growth and survival of Japanese beetle larvae reared in different media, D. LUDWIG and H. FOX (*Ann. Ent. Soc. Amer.*, 31 (1938), No. 4, pp. 445-456, fig. 1).—In attempts to rear Japanese beetle larvae in a variety of media, comprising molds derived from *Andropogon*, *Carex*, and *Osmunda*, dead *Sphagnum*, and such terrigenous products as soil and peat, only the mold derived from *Andropogon* furnished sufficient food for complete development and metamorphosis.

Preliminary notes on a method for the prevention and control of white grub infestations in nursery soils, H. L. MITCHELL (*Black Rock Forest Papers*, 1 (1939), No. 14, pp. 95-97).—An apparently satisfactory preventive measure which also proved effective in the control of existing May beetle (*Phyllophaga* sp.) infestations in nursery soils is described. It was found that treatment of white pine nursery beds immediately after planting with a solution consisting of 0.8 percent acetic acid at the rate of 0.75 qt. per square foot of seedbed to control damping-off is effective against white grubs. In every case one or at most two applications of the acetic acid rid the soil of grubs as well as earthworms and other insect life.

Notes on Pennsylvania flea beetles in tobacco fields (Coleoptera: Chrysomelidae), H. C. HALLOCK. (Pa. Expt. Sta.). (*Ent. News*, 50 (1939), Nos. 5, pp. 121-124; 6, pp. 156-159).—These notes relate to 11 species of flea beetles found in Pennsylvania upon tobacco or upon other plants growing either in the tobacco fields or in adjoining fields. "The most abundant species during April, May, and June was *Epitrix cucumeris*. This species caused severe injury to the foliage of tobacco plants that were growing in seedbeds and that had been recently transplanted. During the same period heavy feeding by *E. cucumeris* was also observed in potatoes and young tomato plants."

Investigations on wireworms and their control (*Univ. Manchester, Ent. Res. Sta., Warburton, Cheshire, Rpt.*, 1 (1937), pp. 31, figs. 8).—Observations of wireworm attack on farm crops in Britain and on the soil, the biology and ecology of wireworms, and investigations on their control, contributed by H. W. Miles, M. Cohen, and R. Stewart, are reported.

Nutrition of certain wood-boring Coleoptera, H. E. SAVELY, JR. (*Jour. Mlisha Mitchell Sci. Soc.*, 54 (1938), No. 2, pp. 195, 196).—A brief report is made of observations in which 22 species of beetles were found to confine their feeding to the phloem of freshly cut pine logs.

On the biology of the Cerambycidae (Coleopt.), C. F. C. BEESON and R. M. BHATIA (*Indian Forest Rec.*, n. ser., *Ent.*, 5 (1939), No. 1, pp. IV-235, pls. 8, figs. 17).—This contribution includes a catalog of trees, shrubs, and woody climbers serving as host plants of Indian Cerambycidae (pp. 202-226).

⁵ Brazil Med., 30 (1916), Nos. 45, pp. 353, 354; 46, pp. 361, 362.

Notes on elm twig crotch injuries produced by *Scolytus multistriatus* Marsham, D. O. WOLFENBARGER and W. D. BUCHANAN. (U. S. D. A.). (*Jour. Econ. Ent.*, 32 (1939), No. 3, pp. 377-381, figs. 9).—These notes are based upon data and observations made over the 5-yr. period 1933-37, in the course of which the crotches of thousands of twigs from several hundred elm trees were examined for injuries.

The preservation of timber against the attacks of the powder post borer *Lyctus brunneus* Stephens by impregnation with boric acid, J. E. CUMMINS (*Jour. Council Sci. and Indus. Res. [Austral]*, 12 (1939), No. 1, pp. 30-44, figs. 3).—The results of laboratory tests have shown that boric acid, borax, or mixtures of boric acid and borax in low concentrations in wood prevented infestation by this borer.

New method of using paradichlorobenzene for seed treatment to control sweetpotato weevil, H. L. DOZIER (*Jour. Econ. Ent.*, 32 (1939), No. 3, pp. 372, 373).—Experiments reported have demonstrated that paradichlorobenzene gas is very slow to penetrate the sweetpotato and requires a long time to kill the weevil under the most favorable conditions. It was shown that a 100-percent kill can be obtained in 13 days, with the possibility that this period can be slightly reduced by a few days.

Life history notes on the cowpea curculio (*Chalcodermus aeneus* Boh.), J. M. LANGSTON. (Miss. Expt. Sta.). (*Jour. Econ. Ent.*, 32 (1939), No. 3, pp. 374-377, fig. 1).—From observations on the biology of this weevil, two generations were reared in each of the years 1935 and 1937 and three in 1936. Most of the adults that emerged on or before September 20 commenced laying eggs the same year, and probably continued the following year. "There are four larval instars, three and part of the fourth being passed in the seed and the remainder of the fourth in the soil. Under favorable conditions adults will emerge in about 20 to 30 days after egg deposition. With the exception of the last generation, which delays oviposition until the following spring, adults begin laying eggs about 10 days after emergence."

Races of bees for Iowa, O. W. PARK. (Iowa Expt. Sta.). (*Philippine Jour. Anim. Indus.*, 5 (1938), No. 6, pp. 611-622).

Methods of destroying red harvester ant nests, R. G. DAHMS and F. A. FENTON. (Okla. A. and M. Col.). (*Pests*, 7 (1939), No. 4, pp. 12-14).

Chalcid flies attacking noxious beetles in India and New Guinea, C. FERREIRE (*Bul. Ent. Res.*, 30 (1939), No. 1, pp. 163-168, figs. 3).—Notes are presented largely on eight species of chalcid parasites of the cotton stem weevil *Pemphera affinis* Fst. in South India, of which four are described as new.

The effect of host size upon the sex ratio of hymenopterous parasites and its relation to methods of rearing and colonization, C. P. CLAUSEN. (U. S. D. A.). (*Jour. N. Y. Ent. Soc.*, 47 (1939), No. 1, pp. 1-9).—A discussion of some of the factors responsible for the fluctuations in the sex ratio of a species, particularly of the parasitic Hymenoptera, and their bearing upon biological control work.

A parasite of the Puerto Rican mole-cricket, G. N. WOLCOTT. (P. R. Col. Expt. Sta.). (*Science*, 89 (1939), No. 2318, pp. 508, 509).—The successful establishment in Puerto Rico of *Larra americana*, a specific wasplike parasite of the changa or Puerto Rican mole cricket *Scapteriscus vicinus* Scudd., following its introduction from Brazil, is reported.

Ecological notes on the *Sirex* wood wasps and their parasites, H. S. HANSON (*Bul. Ent. Res.*, 30 (1939), No. 1, pp. 27-65, pls. 6).—Report is made of a study commenced in 1927. A brief outline of the life cycle of *Sirex* and the parasites is given. The difference in the method of attack by the parasites on

the host is described, and some points of interest in connection with insect behavior are discussed.

The outbreak of the European spruce sawfly in Canada and some important features of its bionomics, R. E. BALCH (*Jour. Econ. Ent.*, 32 (1939), No. 3, pp. 412-418).—Information is given on the life history, number of generations, diapause, reproduction, flight, feeding habits, evidence of European origin, comparison of Canadian and European forms, present distribution, degree of infestation, damage, and future development of outbreak of the European spruce sawfly in Canada.

Effective control of culture mites by mechanical exclusion, H. N. HANSEN and W. C. SNYDER. (Univ. Calif.). (*Science*, 89 (1939), No. 2311, p. 350).—A description is given of a method of controlling mycophagous mites that invade test tubes and destroy pure cultures or contaminate them with other fungi or bacteria. The method, which is based on the positive exclusion of the mites from test-tube cultures by mechanical means, has the advantage over older methods of being effective, nontoxic to fungi, inexpensive, and easily applied.

The seasonal and annual incidence of the sheep tick *Ixodes ricinus* in Britain, J. MACLEOD (*Bul. Ent. Res.*, 30 (1939), No. 1, pp. 103-118, figs. 12).—A report of the work conducted during the years 1930-38 in one or more of the principal tick-infested areas of Scotland and England.

The genera *Dermacentor* and *Otocentor* (Ixodidae) in the United States, with studies in variation, R. A. COOLEY (*U. S. Pub. Health Serv., Natl. Inst. Health Bul.* 171 (1938), pp. V+89, pls. 31, figs. 8).—The author recognizes and gives detailed descriptions and illustrations of seven species of ticks of the genus *Dermacentor*, namely, the American dog tick (*D. variabilis*), *D. andersoni* Stiles, the Pacific coast tick (*D. occidentalis*), *D. hunteri* Bishopp, *D. parumapertus* Neum., *D. halli* McIntosh, and the winter tick (*D. albipictus*), and one of the new genus *Otocentor*, namely, *O. (Dermacentor) nitens* (Neum.).

Amblyomma philipi, a new tick from Texas and Mexico, with a key to known species of *Amblyomma* in the United States (Acarina: Ixodidae), R. A. COOLEY and G. M. KOHLIS (*Pub. Health Rpts. [U. S.]*, 54 (1939), No. 2, pp. 44-47, pls. 2).—Under the name *A. philipi* description is given of a new species of tick collected from the cottontail, jack rabbit, and coyote in Texas.

Variation in *Moniezia expansa* Rudolph, S. R. WILLIAMS (*Ohio Jour. Sci.*, 39 (1939), No. 1, pp. 37-42, figs. 2).—A report of a morphological study of this important cestode parasite of sheep and cattle.

An ecological study of Wyoming spruce-fir forest arthropods with special reference to stratification, E. FICHTER. (Univ. Nebr.). (*Ecol. Monog.*, 9 (1939), No. 2, pp. 183-215, figs. 8).—An account is given of the region, habitat, and methods employed to study the animal population, and quantitative studies of arthropods occurring in a Wyoming spruce-fir forest, accompanied by a list of 36 references. A list of arthropods taken in the spruce-fir forest from June 29 to August 24, 1936, is given in an appendix.

ANIMAL PRODUCTION

[Experiments with livestock in Hawaii] (*Hawaii Sta. Rpt.* 1938, pp. 62-64, 68-74, 83, 84).—Studies for which results are reported include the relative palatability of nine species of native grasses, by R. A. Lyman and J. C. Ripper-ton; the value of cane molasses, soybean oil meal, and fish meal as supplements to pasture for beef cattle, by L. A. Henke, S. H. Work, and A. W. Burt; the use of relatively cheap local feeds in steer fattening rations, the value of pineapple bran for fattening pigs, and the value of roasted soybeans as a protein supplement in swine rations, all by Henke and Work; and the digestibility

of local feeding stuffs, and the utilization of urea nitrogen by swine, both by Work. From tests with poultry results are noted on the use of cane molasses and algarroba bean meal in laying rations, the results of using a laying ration composed entirely of local feeding stuffs, breeding for high egg production and resistance to disease, and temperature conditions in all-steel or semisteel poultry houses, all by C. M. Bice.

[Livestock investigations in Idaho] (*Idaho Sta. Bul.* 229 (1939), pp. 6-10, 12-14, 26, 27, 34, 35, 37-39).—Included are brief progress reports on the seasonal changes in the calcium and phosphorus content of range plants, the phosphorus requirements of steer calves and of growing and fattening lambs, the efficiency of farm-grown feeds in supplying phosphorus for lambs, the returns secured from fattening cut-back yearling steers on pasture, the relative economy of adding protein concentrates to the rations of calves and of yearling steers, a comparison of various protein concentrates in lamb rations, the value of cull potatoes in wintering rations for ewe lambs, and the tonnage of chopped alfalfa hay. From poultry experiments results were noted on the carotene requirements of laying hens, the carotene content of commercial dehydrated alfalfa, the influence of various levels of carotene intake on the carotene content of egg yolks, the relative effectiveness for hens of vitamin A in natural cod-liver oil and in cod-liver oil concentrate, the value of soybean oil meal in turkey growing rations, and the possibility of decreasing mortality of poultry through selective breeding.

[Livestock investigations in Indiana] (*Indiana Sta. Rpt.* 1938, pp. 33-37, 80-83, 90, figs. 2).—Studies for which results are briefly reported include the value of grinding ear corn for steers, mixed-protein v. single-protein concentrates for steers, and rations for raising winter calves, all by F. G. King; the use of supplements of nonleguminous roughages for breeding ewes, and the value of cutting hay for fattening lambs, both by C. Harper; the shrinkage, fill, and yield of hogs trucked to market, and factors affecting the carcass grade of hogs, both by J. R. Wiley; supplemental protein mixtures for growing and fattening hogs, and processed soybeans in brood sow and pig rations, both by C. M. Vestal; the effect of soybeans and soybean products on the quality of pork, the nutritive value and mineral deficiencies of soybeans and soybean products, the effect of hominy feed on the quality of pork, and various factors involved in the production of quality pork, all by C. L. Shrewsbury and Vestal; and the carotenoid pigments contained in farm crops and feeding stuffs, with special reference to their nutritive properties, by H. R. Kraybill, Shrewsbury, and F. P. Zschelle.

Reports of poultry investigations include the reduction of protein in rations for chicks, returns from fine, medium, and coarse ground corn in chick rations, wheat as a substitute for corn in poultry rations, the use of soybean oil meal in broiler rations, by R. E. Roberts and C. W. Carrick; the response of Leghorn pullets to artificial lighting, and wheat v. corn with scratch grains for layers, both by Carrick; the effects of varying ventilation, heat, and humidity conditions in poultry houses, by Carrick and I. D. Mayer; breeding for a specific body size in turkeys, and genetic influence on rate of growth in chickens, both by E. E. Schnetzler; and various phases of poultry management at the Moses Fell Annex Farm.

[Livestock experiments in Louisiana] (*Louisiana Sta., Rice Sta. Bien. Rpt.* 1937-38, pp. 28-32).—Results are briefly reported on the response of permanent pastures in southwestern Louisiana to fertilizer, by R. H. Lush and J. L. Fletcher; and the value of rice byproducts and molasses for fattening beef cattle and lambs, and rations for wintering beef cattle in the rice area, both by M. G. Snell.

[Livestock investigations in Nebraska] (*Nebraska Sta. Rpt.* [1938], pp. 36, 37, 39, 40, 48, 49, 51, 52).—Results are briefly reported for the following studies: Sorghum grains v. corn for fattening steers; a comparison of alfalfa hay, prairie hay, and silage in steer fattening rations; the effect of bonemeal and cottonseed cake as supplements to prairie hay on the blood calcium and phosphorus levels of breeding cattle; silage plus mineral supplements v. alfalfa hay and grain for wintering calves; the relative value of cottonseed cake, soybean oil meal, and tankage as supplements to sand hill meadow hay for wintering range calves; the value of sorghum grains and a comparison of whole alfalfa hay v. cut alfalfa hay for fattening lambs; corn v. sorghum grain when self-fed to pigs in dry lot; the need of protein supplement when grain sorghums are fed to pigs; returns from hogging off grain sorghum; and the value of Sudan grass pasture for pigs.

Reports of poultry investigations include the manganese requirements of growing poults, the value of complex mineral mixtures in a poultry ration, the optimum amount of salt for chicks, the value of grain sorghums for poultry, certain factors affecting the carotene content of poultry feeding stuffs, the effect of applying heat to poultry rations, and genetic differences existing in turkey flocks.

Studies on growth and early maturity, G. H. HART. (Univ. Calif.). (*Vet. Med.*, 34 (1939), No. 4, pp. 212-216).—A review.

Retarded growth, life span, ultimate body size, and age changes in the albino rat after feeding diets restricted in calories, C. M. McCAY, L. A. MAYNARD, G. SPELTING, and L. L. BARNES. (Cornell Univ.). (*Jour. Nutr.*, 18 (1939), No. 1, pp. 1-13, figs. 4).—In an attempt to verify earlier findings (E. S. R., 74, p. 241), rats were retarded in growth for periods of 300, 500, 700, and 1,000 days by providing rations complete except for calories before being allowed to grow to maturity. Those retarded for even 300 days never became as large as those which matured normally. After 1,000 days of retardation, only part of the rats were able to resume growth when adequate energy was provided. However, even at this extreme, males grew to larger size than females. The maintenance of constant body weight did not check the growth of bones. These increased slowly in length and responded to realimentation in all cases after 700 days' retardation, but in only part of the cases after 1,000 days.

Chemical and pathological changes in aging and after retarded growth, C. M. McCAY, G. H. ELLIS, L. L. BARNES, C. A. H. SMITH, and G. SPELTING. (Cornell Univ.). (*Jour. Nutr.*, 18 (1939), No. 1, pp. 15-25, figs. 4).—Certain chemical and pathological changes accompanying aging were studied in the above-described rats. The calcium content of the eye tended to increase in proportion to the time a rat had lived without regard to the degree of retardation of growth, with a rapid deposit of calcium in the eye after animals were 900 days of age. Eye calcium was not correlated with either changes in the bones or with calcification of other tissues. A few animals had intact teeth at very advanced ages, females showing more damage to the teeth than males even though the females had never reproduced. Calcification of the coastal cartilages was much more marked in normal rats than in those of like age that had been retarded in growth. There was a higher incidence of calcification of the aortas in the retarded animals. Limited evidence indicated that retarded animals were less susceptible to lung diseases at 1 yr. of age than normals, also that there was lower incidence of tumors in the retarded ones.

Experiments with the filtrate factor, T. H. JUKES. (Univ. Calif.). (*Jour. Biol. Chem.*, 128 (1939), No. 1, pp. 35-43, fig. 1).—Employing essentially the same methods of assay as previously described (E. S. R., 78, p. 231), further

studies were made to determine certain properties of the filtrate factor. It was found to be destroyed in alkaline solution at 100° C. and by the action of potassium permanganate in acid solution. It was not destroyed in alkaline solution at room temperature or by the action of bromine in acid or alkaline solution. Attempts to form insoluble compounds of the factor with silver, mercury, copper, or cadmium were unsuccessful. Autoclaving yeast or rice bran extract at 120° for 5 hr. had a destructive action on the factor. Other reactions of the factor indicated it to be a comparatively strong organic acid which is dissociated almost completely at pH 6.0.

Growth-stimulating action of ferric chloride-treated wheat germ oil, H. M. EVANS and G. A. EMERSON. (Univ. Calif. et al.). (*Soc. Expt. Biol. and Med. Proc.*, 41 (1939), No. 1, pp. 170-172).—Wheat germ oil treated with ferric chloride so that it contained about one-tenth of the vitamin E activity of the original oil was nearly as effective as the untreated oil in stimulating growth in female rats which had plateaued in weight on the vitamin E-low diet. These findings suggest that the growth-stimulating effect of wheat germ oil is attributable to some constituent other than vitamin E.

Use of liver extract in place of yeast in low fat diets, J. M. MCKIBBIN, J. J. OLESON, C. A. ELVEHJEM, and E. B. HART. (Wis. Expt. Sta.). (*Soc. Expt. Biol. and Med. Proc.*, 41 (1939), No. 1, pp. 25-29).—In the course of a study of deficiencies resulting from low fat diets for rats, it was found that the use of liver extract as a source of the vitamin B complex instead of ether-extracted yeast resulted in earlier and more acute deficiency and hence in a greater growth response when fat was added to the diet.

Radioactive phosphorus as an indicator of phospholipid metabolism.—V, On the mechanism of the action of choline upon the liver of the fat-fed rat, I. PERLMAN and I. L. CHAIKOFF. (Univ. Calif.). (*Jour. Biol. Chem.*, 127 (1939), No. 1, pp. 211-220, figs. 2).—Continuing these studies (E. S. R., 81, p. 88), the rate of phospholipid turn-over was compared in the livers of rats receiving choline (by stomach tube) and untreated rats on the same basal diet with the aid of a radioactive isotope of phosphorus. The administration of choline increased the rate of phospholipid metabolism in the liver, the increase being proportional to the amount ingested within the range tested (0 to 30 mg. of choline chloride per rat). The increased phospholipid metabolism appeared approximately 1 hr. after administration of choline, and its effect disappeared in about 10 to 12 hr. thereafter.

Composition of common California foothill plants as a factor in range management, A. GORDON and A. W. SAMPSON. (Coop. U. S. D. A.). (*California Sta. Bul.* 627 (1939), pp. 95, figs. 25).—This report of an extensive study on the San Joaquin Experimental Range of the U. S. D. A. Forest Service deals with the chemical composition of the chief grass species, the grasslike species, and the broadleaved herbs, shrubs, and arborescents; certain phylogenetic relations; the influence of habitat and season on composition; and the general application of the findings to range management.

Most of the species of grasses, grasslike plants, and broadleaved herbs showed a continuous and rather orderly decline in crude protein, silica-free ash, calcium, phosphorus, and potassium from early growth to plant maturity, while crude fiber increased with advance of season. The levels of protein in these three groups at corresponding growth stages were similar, and the variation in chemical values in the entire life cycle of plants of a given species was greater than between the various species at any single stage of growth. The deciduous shrubs and trees showed the highest average protein level of all the groups, with a gradual downward trend with advance of season.

The deciduous half-shrubs and nondeciduous shrubs had the lowest protein level of the several groups, but showed relatively little change with advance of season. The calcium : phosphorus ratio showed characteristic behavior in the respective plant groups. In grasses the ratio remained at approximately 1 : 1 at all growth stages, while in the other groups there was a marked widening of the ratio with approach of maturity, especially in the deciduous shrubs and trees. A marked consistency in the composition of all constituents within a species through the growth cycle from year to year was evident. The application of these findings in appraising the value of ranges and in range management is fully discussed.

Results of pasture fertilization at Lafayette, Louisiana, R. H. LUSH and J. L. FLETCHER (*Louisiana Sta. Bul. 304 (1939), pp. [1]+21, fig. 1*).—Pasture fertilization experiments were conducted on the rolling prairie soils of southwestern Louisiana over a 10-yr. period, the returns being measured in hay yields and/or by grazing with dairy cattle. Heavy applications of lime without other treatment slightly increased hay yields but decreased grazing returns as compared with untreated areas. Over a 5-yr. period yields were increased 31.4 percent by an annual application of 200 lb. each of nitrate of soda and superphosphate, 26.3 percent by 200 lb. of nitrate of soda, and 26.8 percent by 100 lb. each of muriate of potash, superphosphate, and nitrate of soda, all as compared with yields from untreated areas. An application of 140 lb. of ammonium sulfate decreased the yield 35.6 percent by inhibiting the growth of clovers. Annual applications of 150 lb. of Cyanamid plus two applications of 150 lb. of Ammophoska during the period increased hay yields an average of 66.7 percent. In 1 yr. a 500-lb. application of basic slag gave a 71.7 percent increase in yield. Hay yields on old pasture were more than doubled by a 200-lb. application of nitrate of soda and more than trebled by application of 200 lb. each of nitrate of soda and superphosphate.

In grazing trials with milking cows the feed replacement value from pastures on the basis of prevailing feed prices was \$41.52, \$45.16, \$55.53, and \$58.54 per acre from the untreated pasture and from those receiving complete fertilizer and lime, Cyanamid, and nitrate of soda plus superphosphate, respectively. The composition of the grass as affected by advance of season and by the various fertilizer treatments is indicated. Under the conditions of this experiment a judicious fertilization of pastures is concluded to be a sound and economical practice.

[Pasture fertilization tests in eastern Louisiana] (*Louisiana Sta., Fruit and Truck Sta. Bien. Rpt. 1937-38, p. 22*).—Results are briefly noted.

Commercial feeding stuffs—reports on inspection, 1938, E. M. BAILEY (*Connecticut [New Haven] Sta. Bul. 425 (1939), pp. 99*).—This is the usual report of the guaranteed and found analyses of 888 samples of feeding stuffs collected for official inspection during the calendar year 1938 (E. S. R., 80, p. 84); assays of 55 vitamin D carriers, by R. B. Hubbell and Bailey; and 86 samples examined for poisons, by C. E. Shepard.

Commercial feeding stuffs, L. S. WALKER, E. F. BOYCE, and L. E. DAVIS (*Vermont Sta. Bul. 447 (1939), pp. 48*).—This is the usual report of the analyses for protein, fat, and fiber of 2,046 samples of feeding stuffs collected for official inspection during December 1938 (E. S. R., 81, p. 89).

Cattle fodder and human nutrition, with special reference to biological nitrogen fixation, A. I. VIRTANEN (*Cambridge, Eng.: Univ. Press, 1938, pp. [7]+108, pls. [8], figs. [17]*).—This book comprises four lectures delivered at the Universities of London and Reading in November 1937. The lectures dealt with the mechanism of the biological N-fixation; the symbiosis of the leguminous

plants with the legume bacteria; the production of vitamins in agriculture, with special reference to human nutrition; and the A. I. V. method for the preservation of fresh fodder and its importance in agriculture.

Some effects of the species and stage of maturity of plants on the forage consumption of grazing steers of various weights, W. P. GARRIGUS and H. P. RUSK (*Illinois Sta. Bul. 454* (1939), pp. 441-508, figs. 8).—In the trials reported, the amount of forage consumed by grazing steers was estimated by collection of the feces (collection bags and harness described), determining the dry matter content of the feces, and estimating the forage consumption on the basis of a predetermined ratio between dry matter ingested and dry matter defecated. The relative accuracy of this method with other previously used methods is discussed. A total of 27 grazing trials were conducted on six types of forage with steers ranging from 400 to 1,000 lb. in weight. Expressing the amount of forage consumed in terms of percentage of the net energy maintenance requirement of the steers, the amount consumed by steers on Kentucky bluegrass approximately 5 weeks old was 227-313 percent, on red clover in the $\frac{3}{4}$ -bloom stage 215-259, on red clover on which three-fourths of the blooms had turned brown 199-249, on young second-growth reed canary grass 142-222, on bromegrass in the late-fall-growth stage 116-162, and on alfalfa in the $\frac{3}{4}$ - to full-bloom stage 124-134 percent. The statistical significance of these differences is indicated. The species of forage exerted a greater influence than the size of steers on the rate of forage consumption when expressed as a percentage of net energy maintenance requirements.

Wool growth and quality as affected by certain nutritional and climatic factors.—III, Results and conclusions, J. E. BOWSTEAD and P. LAROSE (*Canad. Jour. Res.*, 16 (1938), No. 12, Sect. D, pp. 361-374).—Continuing these reports (E. S. R., 80, p. 284), a summary of the results indicates that variations in the environmental temperature and humidity had little influence on wool growth and quality. Early-sheared fleeces were slightly coarser and stronger than late-sheared ones. Feeding a submaintenance ration to pregnant ewes during the winter seriously reduced the amount and quality of wool produced. Ewes maintained in fair condition produced fleeces regarded as normal, while heavy feeding slightly increased fleece weight over the normally fed lot. Other variations in dietary regime studied had little influence on wool development.

The relative importance of sow and litter during the growth of suckling pigs: A comparison of fostered with normally reared pigs, H. P. DONALD (*Empire Jour. Expt. Agr.*, 7 (1939), No. 25, pp. 32-42).—In experiments at the University of Edinburgh, paired litters of pigs farrowed at approximately the same time were each divided into two groups, one of which was left with its own mother and the other transferred to the second sow in exchange for a comparable group. Results from 20 litters reared in this way showed an equal and significant variation in growth of pigs up to 3 weeks between litters as born and litters as raised. The weight of pigs at 8 weeks of age was influenced considerably by the sow, but when adjusted for variation in weight at 3 weeks the effect of the litters as born was no longer significant, leading to the conclusion that under these conditions the milk production of the sows is the most important factor in the growth of suckling pigs. The applicability of this method to other investigations concerning suckling pigs is discussed.

[Studies on animal proteins for swine, I, II] (*Meld. Norges Landbr. Høiskole*, 18 (1938), No. 6, pp. 393-459, fig. 1; *Eng. abs.*, pp. 438-444, 457-459).—These studies were conducted at the Institute of Animal Nutrition of the Royal Agricultural College of Norway.

I. *The influence of herring meal and other feeds of animal origin on the quality of pork*, M. Husby (pp. 394-444).—The effects of herring meals of high and low salt content, herring cake, herring oil, a herring-molasses mixture, whale meal, dogfish meal, and tankage on the firmness, color, taste, and odor of pork are reported. The tankage at all levels tested resulted in an excellent quality of pork, while the fish products had to be carefully limited in level of intake to avoid quality defects. Safe levels for the various fish products are indicated. The fat content of the various fish products appeared to be of vital importance in affecting the firmness, color, and taste of the pork.

II. *Content of acids in pig fat*, K. Haug (pp. 444-459).—A comparison of the composition of fat from pigs on high and low levels of herring meal showed that a high level of feeding resulted in a marked increase in the amount of the highly unsaturated acid $C_{20}H_{38}O_2$. The close quantitative relation between herring taste and the content of highly unsaturated C_{20} acids suggests that these acids may be the cause of the herring flavor.

Brewers' grains (fresh) as a pig food: Results of experiments at Wye, V. C. FISHWICK (*Jour. Inst. Brewing*, 45 (1939), No. 3, pp. 119, 120).—In trials comparing the rate and efficiency of gain of groups of pigs (initial weight about 85 lb.) receiving a standard ration for bacon pigs with a comparable group receiving 2 parts of the above ration plus 1 part of fresh brewers' grain, the former group made average gains of 88.8 lb. per pig and consumed 4.03 lb. of meal per pound of live weight gain, while the latter group averaged 82.4 lb. of gain per pig and consumed 3.72 lb. of meal plus 1.83 lb. of brewers' grain per pound of gain. None of the carcasses from the lots receiving the brewers' grain were graded as soft, indicating that, when properly balanced, brewers' grain had no detrimental effect on the quality of the fat.

Nicotinic acid in swine nutrition, L. C. MADISON, R. C. MILLER, and T. B. KEITH. (Pa. State Col.). (*Science*, 89 (1939), No. 2317, pp. 490, 491).—A case is cited of a herd of pigs, weighing from 20 to 45 lb. each, which had become generally unthrifty and was affected with diarrhea and a dermatitis on the body and ears while receiving a ration of corn, oats, wheat middlings, and tankage with some skim milk and access to good grass pasture. Administration of nicotinic acid at the rate of 50 mg. daily per head for 2 weeks caused a marked and rapid improvement in these pigs. Ground alfalfa and cod-liver oil were then included in the ration and within 6 weeks the entire herd had completely recovered and normal growth had been resumed.

Individual and breed variations in pigs on rations devoid of vitamin D, D. W. JOHNSON and L. S. PALMER. (Minn. Expt. Sta.). (*Jour. Agr. Res.* [U. S.], 58 (1939), No. 12, pp. 929-930).—Trials were conducted during three successive winters to determine the vitamin D requirements of growing pigs, representatives of the Chester White, Duroc-Jersey, Hampshire, and Poland China breeds being used during the course of these trials. The basal ration fed throughout contained 0.64 percent of phosphorus and had a calcium : phosphorus ratio of about 1.65 : 1. All trials started in late December or early January, with the pigs confined in heated houses in the complete absence of sunshine. The results gave conclusive evidence that pigs require added vitamin D after their body stores of this vitamin have been depleted. All colored pigs (except two Duroc-Jerseys) which had access to the outside prior to starting on test had vitamin D stores sufficient to protect them from rickets for only from 4 to 8 weeks. White pigs of the Chester White breed and one nearly white Hampshire pig raised under the same conditions prior to the test were protected for approximately twice as long. Following vitamin D depletion, the blood calcium of the pigs fell from a normal of from 10 to 12

mg. per 100 cc. of blood plasma to below 6 mg. When low blood-calcium values were reached tetany occurred, and the reduction was accompanied by a gradual loss of appetite, rough coat, emaciation, and usually lameness.

The Alabama standard for canned dog food, C. J. KOEHN and W. D. SALMON. (Ala. Polytech. Inst.). (*Vet. Med.*, 34 (1939), No. 5, pp. 314-318).—Based on the results of analyses and tests to determine the nutritive value of canned dog foods (E. S. R., 81, p. 408), a standard for canned dog food as described in this article was officially adopted in July 1938.

Seasonal fox rations and quantities to feed, C. F. BASSETT. (U. S. D. A.). (*Amer. Fur Breeder*, 12 (1939), No. 1, p. 20).—Practical rations for adult males, adult vixens, and weaned pups for various seasons of the year are described.

Protein requirements of chickens at various stages of growth and development, A. E. TEPPER, R. C. DUBGIN, and T. B. CHARLES (*New Hampshire Sta. Bul.* 312 (1939), pp. 20).—In two extensive tests to determine the optimum levels and sources of protein intake for chickens during the various stages of growth and production, 12 rations were compared. Protein levels of 15, 17, and 19 percent were used with fish meal, meat scrap, and dried skim milk, each separately and the three in combination, constituting the main source of protein. As the percentage of protein increased a definite increase in body weight of the chicks occurred. Those groups receiving the protein mixture or fish meal alone were definitely heavier at 12 weeks than those on comparable protein levels supplied by meat scrap or dried skim milk. During the growing period (12-23 weeks) the groups on the lower protein levels were most efficient in feed utilization. The groups receiving fish meal as the sole source of animal protein produced a greater number of eggs per bird, had the lowest feed cost per dozen eggs produced, and were earliest in sexual maturity as measured by average days to first egg. The percentage protein in the rations did not significantly influence age at sexual maturity nor size of egg laid. No significant relationship was observed between mortality and the source of animal protein fed. The maximum amount of protein which could be supplied by meat scrap or dried skim milk was definitely lower than in the case of fish meal. A ration containing 13 percent of fish meal (19 percent total protein) did not adversely affect the odor or flavor of either meat or eggs.

Factors affecting manganese utilization in the chicken, H. S. WILGUS, JR., and A. R. PATTON. (Colo. Expt. Sta.). (*Jour. Nutr.*, 18 (1939), No. 1, pp. 35-45).—A more comprehensive report of research noted (E. S. R., 81, p. 410).

Studies on phosphorus metabolism in normal and rachitic chickens with a radioactive phosphorus isotope.—III, The distribution of the injected phosphorus in the organs, especially in the different parts of the leg bones, M. J. L. DOLS, B. C. P. JANSEN, G. J. SIZOO, and G. J. VAN DER MAAS (*K. Nederland. Akad. Wetensch., Proc.*, 42 (1939), No. 6, pp. 499-505, pl. 1).—A more comprehensive report of research previously noted (E. S. R., 81, p. 560).

A study of blood and bone phosphatase in chick perosis, A. C. WIESE, B. C. JOHNSON, C. A. ELVEHJEM, E. B. HART, and J. G. HALPIN. (Wis. Expt. Sta.). (*Jour. Biol. Chem.*, 127 (1939), No. 2, pp. 411-420, figs. 2).—In a further report (E. S. R., 80, p. 674) a revised method for measuring the blood and bone phosphatase activity is described. It was found that the blood and bone phosphatase activity of chicks with perosis was definitely lower than that of non-perotic chicks. In a series of in vitro experiments to determine the effect of various ions on the activity of bone phosphatase it was found that manganese had an activating influence on the enzyme, while calcium and phosphorus ions depressed the activity. Magnesium, which caused some activation of the enzyme, failed to exert a curative effect against perosis in chicks.

The stability of carotene and vitamin A in a mixed ration, R. M. BETHKE, P. R. RECORD, and O. H. M. WILDER. (Ohio Expt. Sta.). (*Poultry Sci.*, 18 (1939), No. 3, pp. 179-187).—The stability of vitamin A in cod-liver oil and carotene in dehydrated alfalfa leaf meal, each incorporated in a mixed ration and stored at approximately room temperature, was determined by chick bio-assays. When either the oil or the meal was incorporated in an ordinary-type ration containing meat scrap and dried skim milk, approximately 75 percent of the vitamin A or carotene was lost after 6 months' storage, although significant amounts of these added factors were still present. When casein replaced meat scrap and dried skim milk in the basal mixture, the rate of vitamin A or carotene loss during storage was markedly reduced, suggesting that the destruction of these factors is influenced by the fat or free fatty acid content of the ration. Addition of 0.1 percent of hydroquinone to the diluted cod-liver oil solution before incorporation in the meat scrap-dried skim milk ration did not decrease the loss of vitamin A during storage.

The vitamin B₂ complex and allied factors: Avian factors, J. R. O'BRIEN (*Cur. Sci. [India]*, 6 (1938), No. 10, pp. 490-493).—A review, with 56 references to the literature.

The ascorbic acid content of blood plasma of laying hens, A. D. HOLMES, F. TRIPP, and G. H. SATTERFIELD. (Univ. N. C. et al.). (*Poultry Sci.*, 18 (1939), No. 3, pp. 192-200).—Following a similar study with chicks (*E. S. R.*, 80, p. 672), the ascorbic acid content of the blood plasma of laying hens was determined. Seven groups of birds were used, the assay on group 1 being made at the beginning of the trial (20 weeks of age); group 2 at 30 weeks of age (10 weeks' egg production); group 3 at 36 weeks (16 weeks' egg production); groups 4, 5, and 6 at 72 weeks (1-yr. egg production); and group 7 at 86 weeks (66 weeks' egg production). The average ascorbic acid content of the plasma was 1.836, 1.129, 1.628, 1.061, 1.288, 1.073, and 1.906 mg. percent for groups 1 to 7, respectively. Individual birds varied widely to give a considerable range within each group. These data reveal very little correlation between the ascorbic acid of the plasma and the egg production, body weight, feed intake, or age of the birds.

Nature and partial synthesis of the chick antidermatitis factor, D. W. WOOLLEY, H. A. WAISMAN, and C. A. ELVEHJEM. (Univ. Wis.). (*Jour. Amer. Chem. Soc.*, 61 (1939), No. 4, pp. 977, 978).—Continuing this line of investigation (*E. S. R.*, 80, p. 673), it was found that a preparation rich in the chick antidermatitis factor could be readily inactivated by treatment with alkali. β -alanine could be isolated from the alkali-inactivated concentrates, and the acidic part of the alkali-inactivated material could be reactivated by coupling with synthetic β -alanine in the manner described. It appeared from these experiments that the chick antidermatitis factor is a hydroxy acid in amide linkage with β -alanine and is very similar in properties to pantothenic acid.

Pantothenic acid and the filtrate factor (chick anti-dermatitis) factor, T. H. JUKES. (Univ. Calif.). (*Jour. Amer. Chem. Soc.*, 61 (1939), No. 4, pp. 975, 976).—Preliminary chick feeding trials in which a heated (filtrate factor deficient) basal diet was supplemented with varying levels of a calcium pantothenate preparation gave evidence that this preparation was markedly active in protecting against chick dermatitis at the 10-mg. level. Comparison with the positive control diet indicated that this preparation had a minimal activity of approximately 8,400 filtrate factor units (*E. S. R.*, 78, p. 281) per gram. A ratio of approximately 5:1 exists between Williams yeast pantothenic acid unit and the chick filtrate factor unit.

Nutritional gizzard lesions in chicks, W. B. ESSELEN, JR. (Mass. Expt. Sta.). (*Poultry Sci.*, 18 (1939), No. 3, pp. 201-209, fig. 1).—A comparison of eight different diets with reference to their effect on the gizzard linings of young chicks showed that the unsupplemented basal diet of Almquist and Stokstad (El. S. R., 77, p. 676) was most effective in producing nutritional gizzard lesions, the lesions being produced within 2 weeks when starting with day-old chicks. The Massachusetts State College chick ration (control) gave practically complete protection against this disorder. The addition of a mixture of 15 percent each of wheat bran, wheat middlings, and oat groats, and 4 percent of alfalfa leaf meal to the Almquist diet gave good protection against the lesions. There appeared to be little correlation between the rate of growth and the severity of the gizzard lesions. In curative trials, dried pork lung, alfalfa leaf meal, soybean meal, oat groats, and wheat middlings were all effective to some degree. Chicks fed an adequate diet for 1 or 2 weeks soon developed gizzard lesions when placed on the deficient basal diet, indicating that very little of the protective factor is stored by the chick. Turkey poults appeared either unsusceptible to this disorder or much more resistant to it than chicks.

Nutritional encephalomalacia in chicks and certain related disorders of domestic birds ([Connecticut] Storrs Sta. Bul. 229 (1939), pp. 121, pls. 20, figs. 8).—This monograph is a comprehensive presentation of accumulated facts which appear to establish nutritional encephalomalacia of chicks as a definite entity in the group of deficiency diseases.

The several chapters discuss the Clinical Picture, by A. M. Pappenheimer and M. Goettsch (pp. 9-14); Pathology, by A. M. Pappenheimer, A. Wolf, and M. Goettsch (pp. 15-24); Brain Weight and Moisture Content, by M. Goettsch and A. M. Pappenheimer (pp. 25-30); Blood Volume, by A. M. Pappenheimer and S. Graff (pp. 31-37); Non-infectious Character of the Disease, by A. M. Pappenheimer (pp. 39-42); Comparison of Natural Foods Diets and Diet 108, by M. Goettsch (pp. 43-48); Protective Experiments With Natural Food Stuffs, by M. Goettsch and A. M. Pappenheimer (pp. 49-58); Preventive Effect of Vegetable Oils and Their Fractions, by M. Goettsch, H. B. Gillespie, and A. M. Pappenheimer (pp. 59-67); The Occurrence of Encephalomalacia in the Field, by El. Jungherr and K. C. Seeger (pp. 69-79); Nutritional Myopathy in Ducklings, by A. M. Pappenheimer and M. Goettsch (pp. 81-88); Nutritional Myopathy of the Gizzard in Turkeys, by El. Jungherr, K. C. Seeger, and A. M. Pappenheimer (pp. 89-96); and Various Forms of Leg Weakness in Chicks: Differential Diagnosis, by El. Jungherr and A. M. Pappenheimer (pp. 97-112).

The general discussion stresses the fact that chicks, ducks, and turkeys develop entirely different pathological symptoms when fed the same deficient diet, the lesions being confined to the brain in chicks, to the skeletal muscles in ducks, and to the smooth muscle of the gizzard in turkeys. Complete protection against chick encephalomalacia is obtained by administering a vitamin E concentrate or α -tocopherol, thus indicating that only one factor is concerned in this disease. A bibliography of 130 references is appended.

Failure of "vitamin K" excess to heal encephalomalacia of chicks, H. C. MASON. (Univ. Ill.). (*Soc. Expt. Biol. and Med. Proc.*, 41 (1939), No. 1, pp. 50, 51).—Experiments at the University of Illinois, in which healthy chicks were fed the Pappenheimer and Goettsch deficiency ration No. 108, gave evidence that nutritional encephalomalacia in chicks is not prevented by the administration of an excess of vitamin K.

Dry skim milk in rations for growing, laying, and breeding fowls, W. H. OTT, H. C. KNADEL, and R. V. BOUCHER. (Pennsylvania Sta. Bul. 381 (1939),

pp. 30, figs. 6).—In three series of experiments eight all-mash rations varying in content of dried skim milk from 0 to 8.75 percent, by 1.25 percent increments, were fed to groups of White Leghorn chickens from 1 day to 72 weeks of age. All groups received 16.9 percent protein starting rations to 12 weeks and 14.4 percent protein rations thereafter. The rate of growth during the first 2 weeks was directly related to the level of dried skim milk in the ration, and total feed consumption and total gain in body weight to 24 weeks increased with increasing levels of milk in the ration, although all groups grew at approximately equal rates from 10 to 24 weeks. The most efficient gains in body weight on the basis of dried skim milk intake were made by the chicks receiving the 1.25 and 2.5 percent levels. Age at sexual maturity decreased with increasing amounts of milk, while body weight at sexual maturity and percentage hatchability of fertile eggs increased with increasing milk levels. From the standpoint of egg production, egg weight, and hatchability the most efficient performance by laying pullets occurred at the 2.5 and 5 percent levels. Results at the 2.5 and 3.75 percent levels were essentially as satisfactory as the higher levels.

Factors influencing market quality and consumer value in poultry meat stock, W. A. MAW (*U. S. Egg and Poultry Mag.*, 45 (1939), No. 4, pp. 204-206, 244).—In studies at Macdonald College, Canada, analysis of carcasses of different breeds of chickens and of the different sex and weight classes within breeds gave evidence that significant differences occur in the edible portion of the carcass within these various groups. Significant differences also existed in the relation of amount of body fat to edible meat, the percentage waste in dressing and drawing, and losses in cooking, all of which affect the use of the carcasses in the home for cooking and serving purposes.

The value of periodical trap-nesting, M. W. OLSEN. (U. S. D. A.). (*Poultry Sci.*, 18 (1939), No. 3, pp. 232-235, figs. 2).—An analysis of first-year trap-nest records of 500 White Leghorn and 390 Rhode Island Red pullets gave evidence that the use of 1-day-a-week records would permit an estimation of actual production with a high degree of efficiency, the standard error of estimates being 18.6 in case of White Leghorns and 19.4 in case of Rhode Island Reds. Testing this method against the actual records of 100 pullets (not used in developing the equations), it was found that 44 percent of the calculated records were within 10 eggs, 58 percent within 15 eggs, and 85 percent within 25 eggs of the actual production. Using 1-day-a-week records through August 31 plus daily records for the remainder of the laying year only slightly improved the accuracy of estimation. The plan of trap-nesting 1 day a week is proposed as a serviceable basis for selecting the most prolific layers for practical poultrymen and progressive farm-flock owners.

The alternate white and yellow layers of yolk in hens' ova, R. M. CONRAD and D. C. WARREN. (Kans. Expt. Sta.). (*Poultry Sci.*, 18 (1939), No. 3, pp. 220-224, figs. 2).—A study of the ovum growth rate throughout the day showed a very slight decrease in rate during the early morning hours, but not enough to indicate any very significant change in the rate of yolk metabolism. By using feeds of different xanthophyll content at different periods of the day alternate white and yellow bands were produced in the egg yolk of hens, while hens receiving a uniform diet throughout the day produced eggs of uniform color, indicating that the visible white and yellow bands frequently observed are the result of periodic intake of varying amounts of xanthophyll and not due to a variation in the rate of metabolism.

High-quality eggs for Illinois markets, H. H. ALP (*Illinois Sta. Cir.* 494 (1939), pp. 31-[1], figs. 23).—This circular offers practical suggestions for the

production, holding, packaging, and marketing of eggs. Principal topics of discussion are the chief causes of small and light eggs; the effect of rations on shell quality; problems concerning egg white, egg yolk, off-flavor, and other common defects; measurement of egg quality; candling technic; farm storage rooms and coolers; grading and packing eggs for market; and ways of preserving market quality.

The measurement of freshness of unbroken eggs, R. H. CARR. (Ind. Expt. Sta.). (*Poultry Sci.*, 18 (1939), No. 3, pp. 225-231, figs. 2).—A test for freshness of whole eggs based on the difference in buoyancy weight of fresh and stale eggs is reported. A special adaptation of the Jolly balance for determining differences in buoyancy weight and the significance of the "Jolly" egg number are fully described. The Jolly number of normal fresh eggs ranging from 50 to 70 gm. was found to be dependent on the dry weight of the yolk and the shell and membrane. The condition of the thick white had a very important effect on the Jolly number. Normal-sized eggs having a Jolly number of only from 25 to 45 are probably old eggs, with evidence that eggs undergo loss of about 1 Jolly number per day.

Storage of shell eggs, T. L. SWENSON. (U. S. D. A.). (*Food. Res.*, 3 (1938), No. 6, pp. 599-608, figs. 5).—A study was made of the effect of oil-treating eggs on their keeping quality. Eggs which were oiled under reduced air pressure showed a marked reduction in permeability (CO_2 evolution), and also markedly less decrease in percentage of thick white and less change in pH during storage as compared with untreated eggs. A large-scale experiment was conducted in which four lots of 200 eggs each were treated as follows: (1) No treatment, (2) oiled in an open immersion pan, (3) oiled as in (2) in oil charged with CO_2 , and (4) oiled by the vacuum- CO_2 method. Half of each lot was put in cold storage immediately, while the other half was transported a considerable distance and then placed in cold storage. The decrease in grade during storage was very high in the untreated lots, considerably lower in lots 2 and 3, and markedly lower in lot 4, over two-thirds of the eggs in the latter group remaining in the two top grades.

The occurrence of mold on egg containers in storage at a Chicago plant, E. TOOP (*U. S. Egg and Poultry Mag.*, 45 (1939), No. 7, pp. 397-399, 448).—An examination of 349 cars of eggs held at 31°F . and 87 percent relative humidity for an average of 8 mo. showed that approximately 49 percent of these cars had some mold development, while the remaining 51 percent showed no evidence of mold. Only 6 percent of the cases were affected by mold at various stages of development. A similar inspection of 50 cars held at 31.5° and 86 percent relative humidity showed 14 percent of all cases attacked by mold. In no case was mold growth noted until after 5 mo. of storage. The variety of wood used in the construction of egg cases was an important factor in this regard, Sitka spruce proving most resistant to mold, while cottonwood was moderately resistant, and tupelo gum quite susceptible. The handling of egg cases prior to placement in storage and actual storage conditions were important considerations.

The vitamin D requirement of young turkeys, T. H. JUKES and T. D. SANFORD. (Univ. Calif.). (*Jour. Nutr.*, 18 (1939), No. 1, pp. 71-85, figs. 2).—In a series of experiments to determine the vitamin D requirement of young turkeys, the bone ash content of the tibia at 4 weeks of age as influenced by various levels of vitamin D in the diet was measured. Maximum bone ash values approximated 50 percent. U. S. P. reference cod-liver oil and a fish oil blend were used as sources of vitamin D. The blend contained about 450 units of vitamin D per gram as determined by chick assays based on the value of 95 units per gram for the reference cod-liver oil. The fish oil blend was more effective,

chick unit for chick unit, than the cod-liver oil as a source of vitamin D for poults, the efficacy ratio being about 1.4:1. Satisfactory growth and calcification in the complete absence of sunlight were produced when turkeys received 0.4 gm. of the fish oil blend per 100 gm. of diet, while significantly poorer calcification resulted when 0.3 gm. was used. Growth rate of poults was markedly influenced by the vitamin D content of the diet. While the vitamin D requirement of turkeys cannot be precisely stated in terms of A. O. A. C. chick units, the value of 200 chick units per 100 gm. of diet was approximately the amount required to support normal development of turkeys to 4 weeks of age.

The use of artificial lights for turkeys, H. L. WILCKE. (Iowa Expt. Sta.). (*Poultry Sci.*, 18 (1939), No. 3, pp. 236-243, figs. 3).—Experiments extending over four seasons gave evidence that turkey females may be brought into earlier egg production by the use of artificial lights either in the morning and evening or all night. It required approximately 6 weeks for turkeys to reach a reasonably high level of production after the lights were turned on. The total number of eggs per bird to the end of June was increased by artificial lighting, while egg weight was not affected. Neither lighting nor heating had any significant influence on fertility or hatchability of the eggs. Total feed consumption was not affected by the use of either heat or light, but heating resulted in a much higher consumption of mash in proportion to grain as compared with the unheated groups.

DAIRY FARMING—DAIRYING

[Experiments with dairy cattle in Hawaii] (*Hawaii Sta. Rpt.* 1938, pp. 65-68).—Included are brief results of feeding tests on the value of algarroba bean meal for dairy cattle, and Sudan grass v. panicum grass or Rhodes grass as roughages for dairy cattle, by L. A. Henke and G. W. H. Goo.

[Experiments with dairy cattle and dairy products in Idaho] (*Idaho Sta. Bul.* 229 (1939), pp. 10, 11).—Progress results are briefly noted on the improvement in the average milk and butterfat production of Jersey and Holstein herds from the continuous use of proved sires and the influence of various factors on the solids-not-fat content of milk.

[Investigations with dairy cattle and dairy products in Indiana] (*Indiana Sta. Rpt.* 1938, pp. 10, 11, 43-48, fig. 1).—Included are brief reports of studies on the vitamin A requirements of cows for the production of butterfat with maximum vitamin A value, the effect of the vitamin A-suppressing factor in soybeans on the transference of the vitamin A per se from the ration to milk fat, and methods for the removal of the vitamin A-suppressing factor from soybean oil, all by S. M. Hauge, J. H. Hilton, and J. W. Wilbur; the influence of input to output in milk production (coop. U. S. D. A.), and the effect of feeds on the fat tests of milk, by Wilbur, Hilton, R. W. Bratton, and W. F. Epple.

Studies with dairy products, by E. H. Parfitt, W. H. Brown, B. E. Horrall, J. C. Crane, Epple, and Hilton, include the cause and remedies of some abnormal flavors in milk, particularly cappy flavor; the physical, chemical, and bacteriological factors affecting body, texture, and quality of ice cream; variations in the lecithin content of milk and its products; factors affecting the quality of Indiana butter; the effect of H-ion concentration, types of micro-organisms, and season on keeping quality of butter; the enzymes in sweet and sour farm-skimmed cream as related to keeping quality of the butter; and comparative studies of methods used in washing and sterilizing milking machines.

Marketing studies, by V. C. Manhart, K. C. Boxell, and Horrall, relate to the effects of quality and associated factors on returns secured by the producer of milk and cream, and consumer reaction to graded butter.

[Experiments in dairying at the North Louisiana Substation], R. H. LUSH (*Louisiana Sta., North Louisiana Sta. Bien. Rpt. 1937-38, pp. 30-32*).—Results are briefly noted on dairy-herd performance, returns from grazing dairy cattle on both winter and summer annual crops, the use of sweetpotatoes in dairy rations, the feeding value of dried sweetpotato pulp, and the response of permanent pastures to fertilization.

The effect of feeding a vitamin A supplement to dairy cattle, J. G. ARCHIBALD and C. H. PARSONS (*Massachusetts Sta. Bul. 357 (1939), pp. 14*).—In an extensive trial extending over 22 mo., the experimental herd of dairy heifers and cows was divided into two comparable groups, one of which received a vitamin A supplement in the form of cod-liver oil concentrate incorporated in the grain mixture while the other group under the same conditions of feeding and management received no supplement. There was no significant difference in the growth rate of heifers (past calfhood stage) in the two groups. There was only a slight difference in the reproductive efficiency of the two groups, but considering all phases the trend was in favor of the supplemented lot. The supplemented group had some advantage in milk production, expressed mainly by greater persistency in milk flow. The average butterfat content of milk was not significantly affected. The vitamin A content of the composite milk samples was higher for the supplemented group, although the transfer of this vitamin from feed to milk was very low in all cases. The addition of a vitamin A concentrate to the ration of dairy cattle is recommended as insurance against trouble due to a deficiency of this vitamin, particularly when the roughage was of poor quality.

Carotene in the nutrition of dairy calves, C. C. FLORA, R. EL. WARD, S. I. BECHDEL, N. B. GUERBANT, and R. A. DUTCHER. (Pa. Expt. Sta.). (*Jour. Dairy Sci.*, 22 (1939), No. 5, pp. 321-323, figs. 2).—Young growing calves fed a ration of skim milk, a low vitamin A concentrate mixture, and poor-quality timothy hay developed vitamin A-deficient symptoms in a relatively short period. The addition of fresh carrots, artificially dehydrated alfalfa hay, or a commercial carotene concentrate to the basal ration was effective in preventing and curing the avitaminosis A. Calves receiving a ration high in cottonseed meal exhibited symptoms similar to those on the low vitamin A diet without cottonseed meal, although the former group developed the deficient symptoms in a much shorter time. This type of malnutrition was also readily corrected when carotene concentrate was added to the diet. The relative amount of vitamin A in the liver tissues corresponded closely to the quantity of carotene supplement administered.

The reproductive efficiency of dairy cattle, A. SPIELMAN and I. R. JONES. (Oreg. Expt. Sta.). (*Jour. Dairy Sci.*, 22 (1939), No. 5, pp. 329-334).—A numerical method of expressing the reproductive efficiency of dairy cattle is described. By applying this method to the breeding records of 368 cows, including four breeds, marked differences were found to exist in the reproductive efficiency of various cow groups and between breeds. The coefficient of correlation between the reproductive efficiency of foundation cows and the mean reproductive efficiency of their respective female descendants was found to be 0.546 ± 0.118 , indicating the importance of selecting foundation cows with high reproductive efficiency.

The partition of the serum globulins of the dairy goat, E. P. REINEKE, V. EL. PETERSON, and C. W. TURNER. (Mo. Expt. Sta.). (*Jour. Biol. Chem.*, 128 (1939), No. 1, pp. 1-7, figs. 3).—Both arterial and venous samples of plasma from dairy goats were treated with a graded series of sodium sulfate solutions, ranging in concentration from 14 to 24 percent, to precipitate the globulins.

All precipitations were carried out at a dilution of 1 : 31. Solubility curves are presented, indicating the changes in solubility of the serum globulins at the various concentrations. Distinct breaks in the curve occurred at the concentrations of 15, 18.5, and 22.5 percent, indicating the partition of the globulin into fractions designated as euglobulin, pseudoglobulin I, and pseudoglobulin II at these respective concentrations. By narrowing the interval between sulfate concentrations, additional breaks in the curve were observed in the vicinity of 16.5 to 17 and at 20 to 21 percent. These are considered to represent subdivisions of pseudoglobulin I and pseudoglobulin II.

[Abstracts of papers presented at the 84th annual meeting of the American Dairy Science Association] (*Jour. Dairy Sci.*, 22 (1939), No. 6, pp. 411-436, 437-458, 459-465, 471-473, 477, 478).—Following are listed the titles and authors of papers pertaining either to dairy manufacturing or dairy production, presented at the annual meeting of the association (E. S. R., 80, p. 94) held at Pullman, Wash., and Moscow, Idaho, June 27-30, 1939: The Use of Sodium Metaphosphate For the Preparation of Soft-Curd Milk, by C. Schwartz, K. K. Jones, T. W. Mack, and R. W. Vance (p. 411); Effect of Certain Sodium Salts Upon the Curd Tension of Milk, by P. H. Tracy and W. J. Corbett (pp. 411, 412) (Univ. Ill.); Further Studies of "Curd Surface" in Relation to the Digestibility of Milk, by L. A. Chambers, I. J. Wolman, and A. P. Hands (p. 412); Photochemical Study of the Irradiation Process of Producing Vitamin D in Milk, by M. J. Dorcas (p. 413); Effect of Concentrating Milk in the Vacuum Pan on the Development of Oxidized Flavors, by W. J. Corbett and P. H. Tracy (p. 413) (Univ. Ill.); Rates of Corrosion in Milk of Certain "White-Metal" Copper Alloys and Their Influence on the Flavor of Milk, by C. L. Roadhouse and J. L. Henderson (pp. 413, 414), and The Rate of Destruction of Vitamin C in Milk as an Index of the Solubility of Copper From Copper-Nickel Alloys, by J. L. Henderson and C. L. Roadhouse (p. 414) (both Univ. Calif.); The Effect of Winter and Summer Rations, and Cod-Liver Oil on the Oxidized Flavors and Vitamin C in Milk, by E. S. Guthrie (p. 415) (Cornell Univ.); Studies on Rancid Milk—Relation of Surface Tension of Rancid Milk to Its Acid Coagulation, by N. P. Tarassuk and F. R. Smith (pp. 415, 416) (Univ. Calif.); A Study of Some Factors Affecting the Viscosity of Market Cream, by F. M. Skelton and H. B. Ellenberger (pp. 416, 417) (Vt. Expt. Sta.); A Comparative Evaluation of an Ice Cream Supply as It Reaches the Consumer, by L. K. Crowe and P. A. Downs (pp. 417, 418) (Univ. Nebr.); Measuring the Quality of Ice Cream, by W. H. Martin, F. E. Nelson, and W. J. Caulfield (p. 418) (Kans. Sta.); Consumer Preference for Individual Chocolate Varieties, by P. S. Lucas and I. A. Gould (pp. 418, 419) (Mich. State Col.); The Use of the Petrographic Microscope in Studying the Different Types of Lactose Crystals as They Occur in Sandy Ice Cream, by W. S. Arbuckle, C. W. Decker, and W. H. E. Reid (p. 419), and The Use of Motion Pictures in Studying the Influence of Several Factors Upon the Stability of Ice Creams and Sherbets, by W. H. E. Reid, W. S. Arbuckle, and C. W. Decker (p. 420) (both Mo. Sta.); A Microscopic Technique for Studying Fat Globules in Dairy Products and Other Oil in Water Emulsions, by W. C. Cole and F. R. Smith (pp. 420, 421) (Univ. Calif.); The Effect of the New Standard Agar on the Plate Counts of Dairy Products, by F. E. Nelson (pp. 421, 422) (Kans. State Col.); The Development on New Standard Milk Agar of Certain Organisms of Importance to the Dairy Industry, by V. D. Foltz and F. E. Nelson (pp. 422, 423) (Kans. Sta.); Regulatory Legislation and Its Relationship to Research in Manufactured Dairy Products, by C. S. Trimble (p. 423) (U. S. D. A.); Studies With the Rollerless Churn, by W. B. Combs and S. T. Coulter (p. 424)

(Univ. Minn.); The Effect of the Ration on Butter Fat Constants, by A. H. Kuhlman and W. D. Gallup (p. 424) (Okla. A. and M. Col.); Some Observations on the Iodine, Reichert-Meissl, and Polenske Values of Milk Fat Produced During the Winter in Three Sections of Oregon, by R. E. Stout and G. H. Wilster (pp. 424, 425), and A Preliminary Report on Investigations to Overcome Crumbly and Sticky Texture in Butter Made During the Winter in the Irrigated Sections of Eastern and Southern Oregon, by G. H. Wilster, R. W. Stein, and R. E. Stout (pp. 425, 426) (both Oreg. State Col.); Copper in Butter, by B. E. Horrall and W. F. English (pp. 462, 463) (Idaho Sta.); Are Urea and Other Simple Nitrogen Compounds Useful in Dairy Feeding? by E. B. Hart, G. Bohstedt, H. J. Deobald, and M. I. Wegner (pp. 463, 464) (Univ. Wis.); The Relation of the Rate of Disappearance of Milk Curd From the Calf's Abomasum to the Apparent Digestibility of Its Protein, by H. C. Dickey, D. Espe, and O. Y. Cannon (pp. 464, 465) (Iowa Sta.); Factors Affecting the Reactions of the Esophageal Groove of Dairy Calves, by G. H. Wise (p. 465) (S. C. Sta.); The Use of Various Oils and Fats for Calf Feeding, by T. W. Gullickson and F. C. Fountaine (pp. 471, 472) (Univ. Minn.); The Influence of Fineness of Grinding on the Digestion Coefficients of Oats for Dairy Cows, by G. C. Wallis, T. M. Olson, and T. A. Evans (p. 472) (S. Dak. Sta.); The Effect of Changes in Environmental Temperature on Water Consumption of Producing Dairy Cows, by W. M. Reagan and S. W. Mead (pp. 472, 473) (Univ. Calif.); Utilization of Proved-Sire Records and Herd-Analysis Data, by J. F. Kendrick (p. 477) (U. S. D. A.); and Utilization on State and County Basis, by W. Gifford (pp. 477, 478) (Mo. Sta.).

Proceedings, thirtieth annual meeting, November 29th and 30th, 1938 (*Amer. Butter Inst., Proc. Ann. Mtg., 30 (1938), vol. 2, pp. [91], pl. 1, figs. 38*).—The following listed papers are published in full in these proceedings: Copper

Contamination, by E. H. Harvey; The Physical State of Milk Fat in Relation to Behavior of Milk Products, by P. F. Sharp (Cornell Univ.); Application of the Phosphatase Test to Creamery Butter, by G. W. Shadwick, Jr.; Temperature's Relation to the Serving Quality of Butter, by W. H. E. Reid (Univ. Mo.); Significance of Mold Mycelia in Butter, by E. H. Parfitt (Purdue Univ.); and Bacteriological Defects of Butter, by B. W. Hammer (Iowa State Col.).

Standard methods for the examination of dairy products: Bacteriological, bioassay, and chemical (*New York: Amer. Pub. Health Assoc., 1939, 7. ed., pp. XI+190, [pl. 1], figs. 22*).—Publication of the seventh edition (E. S. R., 51, p. 579) of this well-known handbook is noted. The body of the text includes a historical introduction and sections on bacteriological methods, bio-assay of vitamin D milk, and chemical methods. An appended section on proposed phosphatase methods for the determination of pasteurization is also included.

An evaluation of the various procedures for making phosphatase tests, L. H. BURGWARD and E. M. GIBBSON. (Ohio State Univ.). (*Jour. Milk Technol., 1 (1938), No. 7, pp. 11-24, fig. 1*).—A series of comparative tests gave evidence that the Kay and Graham, Gilcreas and Davis, and Scharer New York Laboratory tests are all nearly equal in effectiveness for detecting underpasteurization of milk, providing, however, that the standard for the New York Laboratory test is taken as 0.9 p. p. m. of phenol instead of 0.5 p. p. m. as recommended by Scharer. The time and cost of making tests favored the latter. The Scharer Improved Field test proved nearly as effective as any of the laboratory tests and had a distinct advantage of time and cost in its favor. The use of a photometer improved the ease and accuracy of reading the test. It is considered unlikely that bacteria affect its accuracy. Samples could be held 4 or 5 days at refrigeration temperature without noticeably affecting the test.

Application of the rapid phosphatase test to dairy by-products, II. SCHARER (*Jour. Milk Technol., 2 (1939), No. 1, pp. 16-20*).—Detailed directions are given for applying the rapid phosphatase test for efficiency of pasteurization to cream, butter, cheese, and ice cream.

The practical application of the phosphatase test, D. M. ROGER (*Jour. Milk Technol., 2 (1939), No. 1, pp. 21-25*).—Evidence is presented to indicate that the Scharer Rapid Field test when properly applied is highly effective in detecting inefficient pasteurization of milk.

A note on the suitability of various lots of dye for use in the resazurin reduction test, F. E. NELSON. (Kans. Expt. Sta.). (*Jour. Dairy Sci., 22 (1939), No. 5, pp. 335, 336*).—A comparison of four brands of resazurin dye showed marked differences in solubility, color in stock solution and in acid and alkaline solutions, and color changes in milk. These findings suggest the need of standardization of the dye and of certification of different lots of dye by a responsible agency.

The relationship between fat content of fresh milk and its apparent acidity, K. W. LINES. (Univ. Ariz.). (*Jour. Dairy Sci., 22 (1939), No. 5, pp. 337-344*).—The data reported were obtained by determining the titratable acidity and butterfat content of daily individual cow samples of milk over a 4-mo. period. Cows of the Holstein, Guernsey, and Jersey breeds were included, and a total of some 1,300 samples were run. In general, the milks increased in apparent acidity as the fat content increased up to 6 percent, while above that level the acidity decreased. The titratable acidity of the milk tended to decrease with advance of the season from late February to July. Cows in advanced lactation and sick cows produced milk abnormally low in acidity, while cows in the first 30 days of lactation produced milk abnormally high in

acidity. An adjustment of the tolerance limits of acidity in market milk to account for the influence of fat content on apparent acidity is recommended.

Oxidized flavor in milk.—VII, Studies of the effect of carotene and ascorbic acid in the feed of the cow on the susceptibility of the milk to metal-induced oxidized flavor, W. C. BROWN, A. H. VANLANDINGHAM, and C. E. WEAKLEY, JR. (W. Va. Expt. Sta.). (*Jour. Dairy Sci.*, 22 (1939), No. 5, pp. 345-351, figs. 5).—Continuing this series (E. S. R., 81, p. 270), the carotene and ascorbic acid contents and susceptibility to oxidized flavor development were determined on individual milk samples from six cows during periods in which the cows were fed (1) the basal low-carotene ration, (2) basal plus fresh lemon juice or crystalline ascorbic acid, and (3) basal plus carotene concentrate. Adding ascorbic acid to the ration at the rate of 1 gm. per cow daily significantly reduced the tendency for metal-induced oxidized flavor to develop, but did not materially increase the ascorbic acid content of the milk. Adding 350 mg. of carotene per cow daily greatly reduced the tendency for oxidized flavor to develop and also markedly increased the carotene content of the milk. Adding carotene to the ration slightly increased the ascorbic acid in the milk, and, conversely, the ascorbic acid in the ration tended to increase the carotene content of the milk. The mechanism whereby oxidized flavor spontaneously develops is influenced apparently by some factor or factors other than a low carotene level in the ration.

Expulsion of air proposed to prevent destruction of vitamin C and development of oxidized flavor in milk, E. S. GUTHRIE, D. B. HAND, and P. F. SHARP. (Cornell Univ.). (*Milk Plant Mo.*, 28 (1939), No. 4, pp. 26-28).—Tests on a large number of samples of fresh milk from individual cows showed a range from 7 to 41 mg. of ascorbic acid per liter (average 22.2). Similar tests on raw commercial milk samples about 3 days of age showed a range in ascorbic acid of from 0 to 19 mg. per liter (average 8.5), while pasteurized milk showed a similar range but an average of only 2.9 mg. Season and feed of the cow exerted little effect on ascorbic acid content of fresh milk, and pasteurization exerted little accelerative effect on this factor when other modifying variants were eliminated. There was a rather definite relationship between factors which accelerated the rate of oxidation of ascorbic acid and the production of oxidized flavor. Both the destruction of ascorbic acid and oxidized flavor development were largely or completely prevented by removing the dissolved oxygen from the milk.

Problems related to homogenized milk, F. J. DOAN. (Pa. Expt. Sta.). (*Jour. Milk Technol.*, 1 (1938), No. 6, pp. 20-25).—The effect of homogenization of milk on the size of fat globules, curd tension, susceptibility to tallowy flavor development, sediment, bacterial count, color, and other properties is discussed.

The relation of streptococcal mastitis to certain phases of milk sanitation, C. S. BRYAN. (Mich. Expt. Sta.). (*Jour. Milk Technol.*, 2 (1939), No. 1, pp. 32-40, figs. 6).—The relation of streptococcal udder infections of dairy cows to the public milk supply and the need of proper milk ordinances to control this problem are discussed.

A glass milk bottle with narrow pouring lip and minimum drip, L. ARNOLD. (Univ. Ill.). (*Jour. Milk Technol.*, 1 (1938), No. 6, pp. 5-14, figs. 4).—This article describes a standard pouring machine for milk bottles and a standard technic for determining the behavior of milk poured from glass bottles. Tests were conducted on a wide variety of pouring-lip designs on the amount of drip and bacterial contamination from bottles measured. A type of pouring lip giving a minimum drip during the pouring process is described.

Sanitation of paper milk containers, J. R. SANBORN and R. S. BREED. (N. Y. State Expt. Sta.). (*Milk Dealer*, 28 (1939), No. 7, pp. 36, 37, 88-91, figs. 3; obs. in *Milk Plant Mo.*, 28 (1939), No. 5, p. 29).—This discussion deals with the extent to which single-service milk and cream containers are used and the sanitation problems involved in their manufacture and use. Studies in a large number of milk plants indicated that single-service paper containers when made from essentially sterile stock and properly waterproofed and sterilized should be able to meet a standard of freedom from pathogenic organisms even more severe than those enforceable for our present milk containers.

Some factors influencing the amount of mold mycelia in butter, J. ADAMS and E. H. PARFITT. (Ind. Expt. Sta.). (*Jour. Dairy Sci.*, 22 (1939), No. 5, pp. 367-374).—It was found that about 20 to 30 percent of the mold mycelia present in cream was retained in the butter made from that cream. Of various manufacturing operations studied, none had a significant influence on the mold mycelia content of butter. The mold mycelia fragments in butter serve as an index of the length of the holding time, temperature of storage, and oxygen relationships of the cream from which butter is made, but not as a direct index of the organoleptic quality of the cream.

The influence of hydrogen ion concentration and salt on the surface flora of Limburger cheese, C. D. KELLY and J. C. MARQUART. (N. Y. State Expt. Sta.). (*Jour. Dairy Sci.*, 22 (1939), No. 5, pp. 309-320, figs. 2).—Yeast and *Bacterium linens* were previously found to be the predominating types of organisms in the slime of ripening Limburger cheese (E. S. R., 77, p. 693). Yeast was found to grow within a pH range of 3.5 to 8.5 (optimum 6.5), while *B. linens* grew within a pH range of 5.85 to 9.5 (optimum 6.5). In the early stages the surface pH of Limburger cheese falls to 5.0 or lower, which supports yeast but not *B. linens*. Yeast, acting on both protein and lactic acid, soon raises the pH above 5.85, at which time *B. linens* becomes established. A lower pH of the interior of the cheese and also lack of oxygen limits the growth of *B. linens* to the surface. The high concentration of surface salt evidently tends to inhibit the growth of organisms other than yeast and *B. linens*.

Studies on the control of gas in Limburger cheese, C. D. KELLY. (N. Y. State Expt. Sta.). (*Jour. Dairy Sci.*, 22 (1939), No. 5, pp. 299-307, figs. 6).—Results of this investigation reveal that gas production in Limburger cheese, which is a serious problem, is due to the growth of *Escherichia coli* and *Aerobacter aerogenes* bacteria. Because of the relatively high temperature at which the cheese is held for the first 6 hr., the ratio of coliform organisms to other types increases rapidly so that a small number of these organisms in milk may cause excessive gas production in the cheese. Efficient pasteurization, either by the holding method or short-time, high-temperature method, effectively prevented the development of gas. Good quality cheese could be made from the pasteurized milk.

Water sorption by dry milk solids.—I, The effect of processing treatments on volume contraction, E. L. JACK. (Univ. Calif.). (*Jour. Dairy Sci.*, 22 (1939), No. 5, pp. 353-361, figs. 4).—The volume contraction of dry milk solids prepared in various ways when immersed in an unlimited amount of water was measured at 20° C. in a dilatometer. The solids from milk preheated to 76.7° for 30 min. before drying showed greater volume contraction than comparable lots preheated at 60°, 71.1°, 82.2°, or 93.3°. Dry milk solids manufactured by the spray process showed greater volume contraction than those manufactured by the roller process. In general, the volume contraction was completed in from 20 to 22 hr. for spray-process and in from 24 to 28 hr. for roller-process samples. The significance of these findings is fully discussed.

The separation of fat in evaporated milk, B. H. WEBB and G. E. HOLM. (U. S. D. A.). (*Jour. Dairy Sci.*, 22 (1939), No. 5, pp. 363-366, fig. 1).—A study of the effect of certain manufacturing processes and storage time on the separation of fat in evaporated milk gave evidence that high single-stage homogenization pressure or 2-stage homogenization with a high initial pressure and control of the sterilization process to give a heavy-bodied milk were effective in retarding the separation of fat during storage at 28° C.

Preparation of ice cream mixes for home consumption, W. J. CORBETT and P. H. TRACY. (Univ. Ill.). (*Food Res.*, 3 (1938), No. 6, pp. 637-645).—In an effort to develop an ice cream mix which would have a satisfactory body and flavor after canning and sterilization, 15 experimental mixes were prepared, processed, canned, and sterilized. The effect of temperature of sterilization, the relation of composition of the mix and homogenization pressures to heat coagulation, the effect of stabilizers and of egg yolk on heat coagulation, and the effect of storage temperature on certain physical and chemical properties of the sterilized mix were each studied. It was found that by preparing a mix from fresh high-quality dairy products, limiting the total solids to 36 percent and the serum solids to 9 percent, homogenizing at about 2,000-2,500 lb. on the first valve plus 500 lb. on the second, and using a short-time, high-temperature sterilization method, a satisfactory product resulted. Mixes properly flavored and sterilized had only a slightly cooked flavor. Preliminary offerings indicated a favorable consumer acceptance of such a product.

VETERINARY MEDICINE

Draft of an international list of animal diseases (Pretoria: Govt., 1938, pp. 80).—A tabular list arranged systematically under 18 headings, compiled by the South African National Committee of the Veterinary Research Institute at Onderstepoort, including P. J. du Toit, H. O. Mönnig, C. Jackson, and S. W. van Rensburg, at the request of the general secretary. An exhaustive index of 23 pages is included.

Infectious diseases of the domestic animals, L. PANISSET (*Traité des maladies infectieuses des animaux domestiques*. Paris: Vigot Bros., 1938, pp. [4]+562, [fig. 1]).—The more important infectious diseases of livestock are dealt with in this work.

Complex infections, R. E. SHOPE (*Arch. Pathol.*, 27 (1939), No. 5, pp. 915-932).—Discussions of blackhead of turkeys (pp. 914-917), swine influenza (pp. 921-925), type III coryza of fowl (pp. 925-927), and infectious myxomatosis of rabbits (pp. 928-931) are included in this contribution.

[Work in animal pathology by the Idaho Station] (*Idaho Sta. Bul.* 229 (1939), pp. 11, 24-26).—The work of the year reported upon (El. S. R., 80, p. 101) relates to the treatment and prevention of streptococcal mastitis in dairy cows by the use of sulfanilamide (El. S. R., 80, p. 822) and tests for the detection of pullorum disease in poultry.

[Work in animal pathology by the Indiana Station], L. P. DOYLE, A. L. DELEZ, F. L. WALKER, R. A. CRAIG, and C. EL. NEWTON (*Indiana Sta. Rpt.* 1938, pp. 84-87, fig. 1).—Reference is made (El. S. R., 79, p. 679) to studies in 1938 of the transmission of paralysis and leucosis in chicks and of the death loss in newborn pigs; infectious abortion; abortions in clean herds; brucellosis studies in bulls; examination of cats for *Brucella* infection; laboratory diagnoses of poultry and livestock; agglutination tests for Bang's disease (brucellosis) and pullorum disease; and hog cholera serum and virus tests.

[Work with animal diseases by the Nebraska Station] (*Nebraska Sta. Rpt.* [1938], pp. 33-35).—The work of the year reported upon (El. S. R., 79, p.

535) relates to immunity studies of hog cholera and the nature of certain phases of swine erysipelas and the feasibility of simultaneous serum-culture inoculations in its prevention.

Live stock diseases report, No. 14, H. G. BELSOINER (*N. S. Wales Dept. Agr., Livestock Diseases Rpt., 14* (1938), pp. 31).—A report of control work during the year ended June 30, 1938 (E. S. R., 80, p. 250).

Bactericidal efficiency of certain aniline dyes, F. W. TILLEY (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 58 (1939), No. 12, pp. 941-946).—The results of experimental work on the bactericidal efficiency of several aniline dyes against *Eberthella typhi*, *Escherichia coli*, *Salmonella pullorum*, *S. suispestifer*, and *Staphylococcus aureus* are reported, the details being given in tables. The findings indicate that "the addition of phenol or orthocresol to solutions of crystal violet or methyl violet 2B greatly increases their bactericidal efficiency against Gram-negative bacteria. There is little or no increase in efficiency against Gram-positive bacteria. The addition of phenol or orthocresol to solutions of brilliant green or malachite green has little or no effect on their bactericidal efficiency. The addition of sodium carbonate to aqueous solutions of crystal violet markedly increases bactericidal efficiency. The addition of sodium borate or disodium phosphate to such solutions produces little or no effect. In contaminated hog-blood mixtures kept at incubator temperature, crystal violet (1-2,000) with 0.02 M sodium carbonate appears to be uniformly ineffective, with 0.02 M disodium phosphate usually effective, and with 0.02 M sodium borate uniformly effective, in killing the contaminating bacteria."

Some observations on the toxicology of linseed plant (*Linum usitatissimum* Linn.), K. N. BAGCHI and H. D. GANGULI (*Indian Jour. Vet. Sci. and Anim. Husb.*, 9 (1939), No. 1, pp. 61-66).—It was found that flax flowers with immature seeds, a fairly common source of cattle poisoning in Bengal and Bihar, contain the maximum amount of the cyanogenetic glucoside (producing as much as 0.69 percent of free hydrocyanic acid) and may be regarded as most potent cattle poisons. A half a pound of these flowers is sufficient to kill a bullock.

"Actinomycosis" and actinobacillosis in animals in India, M. Y. MANGRULKAR (*Indian Jour. Vet. Sci. and Anim. Husb.*, 8 (1938), No. 4, pp. 271-291, pls. 6).—Included in this discussion is a description of a few cases from the bullock, buffalo, and dog in India.

Some experiments on the extra-corporeal hatching of the eggs of *Ascaris suum*, D. W. FENWICK (*Jour. Helminthol.*, 17 (1939), No. 2, pp. 69-82).—Temperature, osmotic pressure, pH, and alkali were not in themselves sufficient to cause hatching of the eggs of *A. suum*. The digestive enzymes were incapable of inducing hatching, at least in vitro. "Agitation of the eggs cannot be considered as a biological method of inducing hatching, and it is therefore improbable that they throw any light on the process."

Comparative results of tube and plate tests for Bang's disease on suspicious animals, C. ELDER (Mo. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 95 (1939), No. [748], pp. 38-43).—Comparative results on 12,006 blood samples, most of which had originally been found suspicious to the tube test, showed a rather close agreement when the results of the tube and plate methods were studied. "Comparative results did not show either test to be greatly superior in reducing the number of suspects, but a slightly smaller number of suspicious reactions were obtained by the plate method of testing. If readings in all cases with the plate method had been taken at the end of 8 min. instead of final readings, where delayed or slow reactions were observed, the number of suspects by this method would have been larger. On this particular group of samples studied,

a larger number of reactors were found with the plate method than by the tube method of testing. It was found, when comparing the two tests, that there was a great difference if one reported incomplete 1:50 reactions as non-reactors or as suspicious. The difference between results when incomplete 1:50 reactions are classified as nonreactors, as compared with results when they are classified as suspects, may in part account for some of the apparent variations in the agglutination test when reported by various laboratories. This study further illustrates the importance of uniform methods of testing and reporting results."

Accomplishments and difficulties in the control of Bang's disease, R. R. BIRCH (*Cornell Vet.*, 29 (1939), No. 2, pp. 173-181).

Immunobiological studies on *Brucella abortus* Bang for establishment of a serviceable allergic diagnostic means, N. PLUM and C. RUSSEFF (*Skand. Vet. Tidsskr.*, 29 (1939), No. 1, pp. 31-53, figs. 5; *Dan. abs.*, p. 52).—A contribution from the State Veterinary Serum Laboratory, København (Copenhagen).

Treatment of *Brucella abortus* infection with Fouadin and Prontosil, A. P. THOMSON (*Brit. Med. Jour.*, No. 4060 (1938), pp. 884, 885; *abs. in Vet. Rec.*, 50 (1938), No. 52, p. 1780).—Report is made of five cases of *B. abortus* infection in man, three of which were treated with Fouadin, a Bayer preparation containing a detoxicated complex salt of trivalent antimony and pyrocatechin, and four with Prontosil. All five showed high agglutination titers in their blood before treatment. The titer fell after treatment with Prontosil, and all apparently showed some benefit. The findings indicate that in the treatment of this disease both Prontosil and Fouadin are of value, and that Prontosil may prove to be a simple specific remedy when the patient can tolerate it in moderate doses (about 3 gm. daily) for a week.

Cheilospirochaeta centrocerci, a new nematode from the sage grouse (*Centrocercus urophasianus*), F. SIMON. (*Wyo. Expt. Sta.*). (*Amer. Micros. Soc. Trans.*, 58 (1939), No. 1, pp. 78-80, figs. 3).

The effect of X-ray on the coccidia of the rabbit, R. F. HONESS. (*Univ. Wyo.*). (*Science*, 89 (1939), No. 2317, p. 486).—A brief report is made of experiments which indicate that laboratory animals as well as valuable stock and pets may be freed from coccidia by the use of X-rays.

Avian hosts of eimerian coccidia, D. C. BOUGHTON and J. J. VOLK. (*Univ. Ga.*). (*Bird-Banding*, 9 (1938), No. 3, pp. 139-153, fig. 1).—The authors present a classified list of avian hosts with the respective species of the coccidian genus *Eimeria*. The host list includes 37 species of birds, which represent 31 genera, 13 families, and 8 orders. "For each of the 34 species of *Eimeria* which have been reported from these hosts brief notes are given on the following: Oocyst characteristics, tissue stages, prevalence and geographical distribution, pathogenicity, host specificity, and pertinent references. Of the 37 species of birds 4 are reported here for the first time as hosts of *Eimeria* sp. These are *Columba leucocephala*, *Zenaidura macroura carolinensis*, *Melopelia a[statica] asiatica*, and *Oreopeleia chrysis*."

A bibliography of 42 titles is included.

Foot-and-mouth disease in man, A. FLAUM (*Acta Pathol. et Microbiol. Scand.*, 16 (1939), No. 2, pp. 197-213, pl. 1, fig. 1).—This is a report of four cases of foot-and-mouth disease in man confirmed by animal experiments, presented with a list of 24 references to the literature.

Species of helminth parasites of domestic animals in Texas, H. L. VAN VOLKENBERG. (*Tex. A. and M. Col.*). (*Vet. Med.*, 34 (1939), No. 8, pp. 465-467).

The effects of number and age of worms on development of primary and secondary infections with *Hymenolepis diminuta* in rats and an investiga-

tion into the true nature of "premunity" in tapeworm infections, A. C. CHANDLER (*Amer. Jour. Hyg.*, 29 (1939), No. 3, Sect. D, pp. 105-114).—The results of experimental work with *H. diminuta* are reported.

A study of the rate of reproduction in the avian malaria parasite *Plasmodium cathemerium*, G. H. BOYD. (Univ. Ga.). (*Amer. Jour. Hyg.*, 29 (1939), No. 3, Sect. C, pp. 119-129, figs. 3).—Observations on 30 infections of canaries with *P. cathemerium*, with information on the number of merozoites produced by the schizonts of this parasite in their process of schizogony and upon the rate of destruction of the parasites in these infections, are reported.

Mastitis: What do we know about it? E. C. McCULLOCH. (Wash. State Col.). (*Wash. State Col., Inst. Dairying Proc.*, 11 (1938), pp. 127-130).—

Myiasis in domestic animals, E. W. LAAKE. (U. S. D. A.). (*Jour. Amer. Vet. Med. Assoc.*, 95 (1939), No. [748], pp. 47-49).—A practical discussion which includes measures of prevention and treatment.

A new prophylaxis for wound myiasis in domestic animals, M. A. STEWART (Univ. Calif.). (*Jour. Econ. Ent.*, 32 (1939), No. 3, pp. 404-407).—The author has found that "a mixture composed of 25 percent acid free, dehydrated Stockholm pine-tar oil with a specific gravity of 1.075, 12.5 percent amorphous paraffin wax with a U. S. P. melting point of from 160°-170° F., and 62.5 percent viscous oil with the following specifications: Flash point Cleveland 540° maximum, viscosity at 100° Saybolt universal 144,200, viscosity at 210° Saybolt universal 2,900-3,200, pour point +50° maximum, color A. S. T. M. 2.0 maximum, carbon Conradson 0.5 percent maximum, sulfur bomb 0.5 percent maximum, and Sligh test 1.0 maximum, applied to wounds over an oakum substratum when a sinus is present and where a sinus is not present after the wound has been dried by the application of motor ether or tannic acid, affords efficient protection against myiasis and also greatly stimulates tissue repair in the wounds. Its prophylactic efficiency is based upon both a chemical repellent and a mechanical barrier, and wound drainage is not inhibited."

The viability of rinderpest goat blood virus at incubator temperatures, P. G. MAHKANI (*Indian Jour. Vet. Sci. and Anim. Husband.*, 9 (1939), No. 1, pp. 39-47, figs. 4).—The author has found that citrated rinderpest goat blood virus alone is viable on the sixth day of incubation at 37° C.; when mixed with Voges Proskauer's solution and kept at 39°, it was viable on the fifteenth day but nonviable on the seventeenth day. Defibrinated blood virus mixed with Voges Proskauer's solution kept at 39° is viable on the thirteenth day but nonviable on the fifteenth.

Reversibility of the alpha and beta phases of *Salmonella typhi*, P. R. EDWARDS and D. W. BRUNER. (Ky. Expt. Sta.). (*Soc. Expt. Biol. and Med. Proc.*, 41 (1939), No. 1, pp. 223, 224).

"Hypo-HCl" treatment of scabies, W. S. PARKER (*Lancet [London]*, 1939, I, No. 17, p. 987).—Reference is made to the so-called hypo-HCl method of treating scabies. The skin is painted with a 25 percent aqueous solution of sodium thiosulfate, commonly known by photographers as "hypo," allowed to dry, and then painted with 5 percent hydrochloric acid. This is repeated, so that a single treatment consists of two alternate applications of hypo and acid, resulting in a very fine deposit of sulfur on the skin. All of the cases treated by the author cleared up after one treatment. The method is entirely free from discomfort or risk and may be applied anywhere.

A brief review of the species of schistosomes of the domesticated animals in India and their molluscan hosts, M. A. R. RAO (*Indian Vet. Jour.*, 15 (1939), No. 4, pp. 349-358).

Studies on the bionomics and control of the bursate nematodes of horses and sheep.—VI, On the lethal effects of some nitrogenous chemicals on the free-living stages of Sclerostomes, I. W. PARNELL (*Canad. Jour. Res.*, 17 (1939), No. 3, Sect. D, pp. 68-86, figs. 9).—This further contribution (E. S. R., 80, p. 102) discusses the effect of 10 chemicals containing a nitrogen radicle on the free-living stages of Sclerostomes. "Chloropicrin is the most lethal chemical yet tested; under the conditions of these tests, one part of chloropicrin will sterilize approximately 2,300 times its weight of feces, but its disadvantages weigh against its practicability for farm use. Aniline will sterilize about 525 times its weight of fresh feces when undiluted and 800 or 900 times its weight as a very weak solution. Calcium cyanide, whose value is also limited by its danger, will sterilize 530 times its weight of fresh feces. Pyridine is slightly more effective when applied undiluted or as a strong or medium strength solution; it will then sterilize about 400 times its weight of fresh feces. Ammonium carbonate will sterilize approximately 50 times its weight of fresh feces. Ammonium chloride, cupric nitrate, and ammonium nitrate will sterilize approximately 30, 25, and 21 times their own weight of fresh feces, respectively. They are, however, more effective if applied as medium strength solution, and cupric nitrate in lesser amounts causes the death of many larvae after they have reached the third stage, although the chemical was added to the fresh feces. Ammonium sulfide, as a 15 percent solution, will sterilize nearly 14 times its weight of fresh feces. Saponin probably has no lethal value against Sclerostomes chemically, although physically it may affect them."

The pathogenic staphylococci, J. E. BLAIR (*Bart. Rev.*, 3 (1939), No. 1, pp. 97-146).—This contribution is presented with a bibliography of 263 titles.

The ticks of domestic animals in Britain, J. MACLEOD (*Empire Jour. Expt. Agr.*, 7 (1939), No. 26, pp. 97-110, pls. 2, figs. 2).—A practical summary of information.

Diseases transmitted by the Indian species of ticks and the possibility of their prevention through biological control, M. SHARIF (*Indian Jour. Vet. Sci. and Anim. Husb.*, 8 (1938), No. 4, pp. 353-366).—Presented in this contribution are lists of species of ticks (1) which are of considerable economic importance in India and attack domestic animals in large numbers, with their usual hosts, (2) which are found on domestic animals, but are of comparatively less economic importance, with their usual hosts, and (3) that have been involved in the transmission of diseases in India or in other countries.

On the presence of a buccal stylet in adult *Trichinella*, and the mode of feeding of the adults, V. D. VAN SOMEREN (*Jour. Helminthol.*, 17 (1939), No. 2, pp. 85-92, fig. 1).—A description is given of a functional buccal stylet occurring in adult male and female *T. spiralis*, and of the mode of feeding of the adults examined immediately on removal from the intestines.

The relative susceptibility of the field-vole to the bovine, human, and avian types of tubercle bacilli and to the vole strain of acid-fast bacillus (Wells, 1937). A. S. GRIFFITH (*Jour. Hyg. [London]*, 39 (1939), No. 3, pp. 244-259).—Report is made of an epizootic disease among field voles (*Microtus agrestis*) in England resembling tuberculosis in its anatomical features but due to an acidfast bacillus different from the tubercle bacilli found in other species of warm-blooded animals. The study has led to the following conclusions: "(1) The vole is susceptible to infection with all the four types of acidfast bacilli used. (2) The bovine tubercle bacillus is the most virulent, and when injected parenterally or introduced by feeding gives rise to generalized progressive tuberculosis which runs a rapid course and is characterized by caseation of the lesions, especially the glandular, and great multiplication of

the bacilli. (3) The human tubercle bacillus can multiply in the tissues of the vole and cause death but does not, except locally and occasionally elsewhere, provoke tuberculous tissue changes leading to the formation of visible lesions. (4) The avian bacillus acts in much the same way as the human bacillus, having little tendency to produce macroscopic lesions. (5) The vole strain of bacillus can infect the vole through abrasions in the skin, or when taken with the food, or injected parenterally. The generalized disease produced experimentally by the vole bacillus is distinguished from that set up by bovine bacilli by its more chronic course and by the occurrence in the areolar tissues of masses of necrotic or caseous substance largely composed of acidfast bacilli. (6) The vole appears to react in a characteristic manner (general lymph-gland caseation) to all strains of bovine tubercle bacilli, whether these are fully virulent for the rabbit or so reduced in virulence for that animal as not to be clearly distinguishable by the rabbit test from tubercle bacilli of the human type. (7) These results suggest that the vole may prove of great value in ordinary typing of tubercle bacilli and for testing strains which, though culturally bovine, have given equivocal results in rabbits."

Spontaneously acquired tuberculosis in rhesus monkeys, K. C. SMITH-BURN (*Amer. Rev. Tuberc.*, 39 (1939), No. 5, pp. 675-682).—In this work 18 strains of tubercle bacilli were isolated from as many cases of spontaneously acquired tuberculosis in rhesus monkeys. In about half the monkeys the primary lesion was apparently in the gastrointestinal tract. Fifty percent of the strains were of bovine type. Evidence was gathered which indicates that a portion, at least, of the animals were tuberculous when imported. The importation of tuberculous monkeys for zoological exhibition may constitute a public health hazard.

Immunity experiments on guinea-pigs with killed tubercle bacilli and BOG, A. S. GRIFFITH and R. E. GLOVER (*Jour. Compar. Path. and Ther.*, 52 (1939), No. 1, pp. 57-68).—In the experiments reported, each of the five vaccines—four of virulent tubercle bacilli killed by heat (60° and 120° C.), formalin, and glycerin, respectively, and one of B. C. G.—raised the resistance of the great majority of the guinea pigs to infection with virulent bovine bacilli. The increase of resistance was not of a high order and was effective in diminishing the extent and severity of the generalized tuberculosis in only 50 percent of the guinea pigs. In about two-thirds of the remainder the vaccine exercised only a slight retarding influence on the progress of the tuberculosis and in the rest none at all. On the whole the best results were given by B. C. G., one animal in this group showing lesions which were confined practically to the seat of injection and the adjacent glands, but there was little to choose between the results with the living vaccine and some of the dead vaccines.

Observations on the bovine blood picture in health and under parasitism, E. DELAUNE. (La. State Univ.). (*Soc. Expt. Biol. and Med. Proc.*, 41 (1939), No. 2, pp. 482, 483).—"Observations made on 6 normal Jersey and Holstein calves between the ages of 2 days and 6 mo. showed an average of 8.70 million red cells, 10,674 white cells per cubic millimeter of blood, and a differential leucocytic count as follows: Lymphocytes 64.4 percent, monocytes 12.2 percent, neutrophils 19.6 percent, [and] eosinophiles 3.3 percent.

"Six counts made on each of 5 adult animals between the ages of 3 yr. and 6.5 yr., which were on range and which were considered to be normal from the standpoint of the absence of disease, revealed an average of 6.39 million red cells and 10,225 white cells per cubic millimeter of blood, with a differential leucocytic count of lymphocytes 53.1 percent, monocytes 8.0 percent, neutrophils 25.9 percent, [and] eosinophiles 7.0 percent."

The bovine kidney in health and disease, R. LANGHAM and E. T. HALLMAN. (Mich. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 95 (1939), No. [748], pp. 22-32, figs. 24).—Observations of the anatomy of the normal and diseased bovine kidney and the theory of kidney function are presented with a list of 11 references to the literature.

Some causes of abortion in cattle free from Bang's disease, H. L. GILMAN (*Cornell Vet.*, 29 (1939), No. 2, pp. 153-165).—Some of the various factors that have been known to interfere with the implantation and development to normal maturity of the bovine fetus, as well as others that were held under suspicion, are briefly considered, accompanied by a bibliography of 32 titles.

Coccidiosis, W. J. GIBBONS and D. W. BAKER (*Cornell Vet.*, 29 (1939), No. 2, pp. 182-191, fig. 1).—Case reports of coccidiosis occurring in 10 herds of cattle are presented.

Three cases of bovine mastitis due to unidentified non-hemolytic streptococci, R. B. LITTLE (*Cornell Vet.*, 29 (1939), No. 2, pp. 100-104).—Report is made of the cultural characters of strains of unidentified (atypical) streptococci which were responsible for three acute cases of mastitis in a self-contained herd in New Jersey.

Experiments on the transmission of bovine contagious pleuro-pneumonia, with a report on a new method of testing immunity following vaccination, R. W. M. METTAM and J. FORD (*Jour. Compar. Pathol. and Ther.*, 52 (1939), No. 1, pp. 15-28, figs. 4).—The authors have found the intrajugular inoculation of agar plugs containing lymph or culture to be an effective and rapid method of producing, experimentally, lesions of contagious pleuropneumonia. In susceptible cattle there are often well-marked clinical symptoms following a period of incubation which averages 1 week. In more resistant animals symptoms are vague or absent even though there may be well-developed lesions in the thorax. "The vaccine test, although used on comparatively few animals, proved satisfactory and deserves a more extended trial. Out of the 10 test animals only 1 showed evidence of having reacted to the inoculation of embolus containing virus. In 2 control tests, 5 out of 10, respectively, showed extensive lesions of contagious bovine pleuropneumonia."

Detectable antibodies in the sera of cows affected with group-B streptococci, D. F. STEWART (*Austral. Vet. Jour.*, 15 (1939), No. 1, pp. 12-14).—Report is made on the presence of antibodies in the sera of cows infected with group-B streptococci, to which no reference in literature has been found by the author.

The potency of synthetic medium tuberculin for use in the double intradermal test in cattle, R. F. MONTGOMERIE and A. THOMSON (*Vet. Rec.*, 50 (1938), No. 52, pp. 1759-1772).—It was found that synthetic medium tuberculin (ammonium sulfate precipitated) as originally prepared in the authors' laboratories was too potent to be used in the double intradermal test. This tuberculin had some tendency to produce pseudo-positive reactions in clean cattle. "Diluted to a potency approximately equal to two-fifths International Standard Tuberculin, as judged by the guinea pig intracutaneous test, it (L. C. tuberculin) appeared suitable for this purpose."

Venereal infections of cattle: Their manner of spread and their eradication, S. H. McNUTT and F. EL. WALSH. (Iowa State Col.). (*Vet. Med.*, 34 (1939), No. 8, pp. 468-473, fig. 1).—The nonspecific venereal infections of cattle are dealt with. A plan for the correction of such infections in individual herds is suggested.

Experiments in calves on immunity conferred by single and double injections of BOG in an oily excipient, J. B. BUXTON and R. EL. GLOVER (*Jour. Compar. Pathol. and Ther.*, 52 (1939), No. 1, pp. 47-56).—In further experi-

ments (E. S. R., 76, p. 849) "the subcutaneous inoculation of three calves with 5 mg. of B. C. G. incorporated in gum acacia and olive oil failed to induce an appreciable immunity to the oral administration of cultures of virulent tubercle bacilli 6 mo. later. When the dose of B. C. G. was increased to 50 mg., a moderate protection was obtained in three calves out of four. A reinforcing inoculation of B. C. G. given under the same conditions 12 mo. after a primary dose induced a partial protection to the same infecting dose administered 6 mo. after the second injection of the vaccine. There were marked individual differences, however, since three calves out of six were completely protected, while in the remainder the lesions were almost as severe as in the controls."

A study of the life-history and pathogenicity of *Cotylophoron cotylophorum* (Fischöeder 1901) Stiles and Goldberger 1910 of Indian ruminants and a biological control to check the infestation, H. D. SRIVASTAVA (*Indian Jour. Vet. Sci. and Anim. Husb.*, 8 (1938), No. 4, pp. 381-385, pls. 4).—A contribution from the Imperial Veterinary Research Institute, Mukteswar-Kumaun.

The destruction of *Lymnaea philippinensis* for the control and eradication of fascioliasis in ruminants, Z. DE JESUS (*Philippine Jour. Anim. Indus.*, 5 (1938), No. 6, pp. 581-595, pls. 6).—Experimental control work with the intermediate snail host of liver flukes, parasitic to cattle and carabaos and abundant in most, if not all, of the larger islands of the archipelago, is reported. It is pointed out that since laboratory and field observations have shown that this snail and its eggs will not withstand desiccation, its destruction may be obtained by draining or by not irrigating its habitat during the dry season in places where there are two distinct seasons of the year.

A new system of anthelmintic control for gastro-intestinal parasites of ruminants, D. W. BAKER (*Cornell Vet.*, 29 (1939), No. 2, pp. 192-197, figs. 2).

A survey of the incidence of surra in Philippine cattle and carabaos by complement fixation test.—Preliminary report, T. TOPACRO and R. A. ACEVEDO (*Philippine Jour. Anim. Indus.*, 5 (1938), No. 6, pp. 597-604, fig. 1).—The results obtained in a preliminary survey of the incidence of surra in cattle and carabaos by the complement-fixation test are reported. They are said to indicate a necessity for further continuance of the work in order that the entire archipelago may be covered to obtain a factual picture of the surra situation in the various localities.

A note on *Anaplasma* and on *Bartonella sturmani* sp. nov. in the buffalo, K. GRINBERG (*Ann. Trop. Med. and Parasitol.*, 33 (1939), No. 1, pp. 31-36).—A description is given of a natural infection in splenectomized buffaloes by a parasite morphologically indistinguishable from *A. marginale*. This parasite from young buffaloes from the Huleh swamps of Palestine was transmitted to calves by direct blood inoculation, the infection in the calf being indistinguishable from natural infections of *A. marginale*. A description is also given of a new species of a *Bartonella* (*B. sturmani*) from a splenectomized buffalo, which can be transmitted by direct blood inoculation from buffalo to buffalo, but not from buffalo to calf.

Notes on a hitherto unreported acarine parasite of carabao in the Philippines, L. M. YUTUC (*Philippine Jour. Anim. Indus.*, 5 (1938), No. 4, pp. 363-367, pls. 5).—A description is given of the acarine parasite *Psoroptes communis bovis*, first observed in the Philippines in 1912 in a shipment of carabaos from Taiwan (Formosa). A brief report is made on its experimental transmission, symptoms, and treatment.

Diseases of breeding ewes, A. LESLIE (*Auckland, New Zeal., and London: Whitcombe and Tombs, 1938, pp. 147, [figs. 17]*).—The subject is dealt with in

three sections under the headings of diseases and disorders of pregnancy (pp. 7-60), parturition (pp. 61-113), and lactation (pp. 114-144).

Investigations on Johne's disease of sheep, A. D. McEWEN (*Jour. Compar. Pathol. and Ther.*, 52 (1939), No. 1, pp. 69-87).—Report is made of an outbreak of Johne's disease in a flock of sheep, the symptoms and lesions of the affected sheep being described. The causative organism resisted cultivation and so differed from the Johne bacillus isolated from cattle. The infection was readily transmitted to lambs, but adult sheep were resistant. Six calves exposed to heavy infection all became infected. Johnin diagnostic tests carried out on sheep and on the experimental cattle were unsatisfactory.

The control of stomach worms in sheep in eastern Canada, W. E. SWALES (*Canada Dept. Agr. Pub.* 639 (1939), pp. 7, figs. 3).

A new technique for counting nematode eggs in sheep faeces, H. M. GORDON and H. V. WHITLOCK (*Jour. Council Sci. and Indus. Res. [Austral.]*, 12 (1939), No. 1, pp. 50-52, fig. 1).—A description is given of a method by which the work of counting nematode eggs in sheep feces is simplified and the time required for each sample reduced about one-half.

Efficacy of commercial phenothiazine in the removal of roundworms from sheep, P. D. HARWOOD, R. T. HABERMANN, and A. C. JERSTAD. (U. S. D. A.). (*Vet. Med.*, 34 (1939), No. 7, pp. 440-443, fig. 1).—In experiments reported, "commercial phenothiazine, which contains about 95 percent of this compound, removed 76.7 percent of the hookworms and 90.9 percent of the nodular worms from eight sheep when the substance was administered at the rate of 0.5 gm. per pound of body weight. Commercial phenothiazine at a dose rate of 0.25 gm. per pound of body weight was much less effective in two animals than when given at a dose rate of 0.5 gm. per pound of body weight. The chemical appears to have been 100 percent effective for the removal of *Ostertagia* and fairly effective for the removal of *Haemonchus*. A practical method for the administration of phenothiazine to sheep has not been developed, but further work in this direction is in progress."

Stiff lamb disease in Michigan, L. B. SHOLL. (Mich. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 95 (1939), No. [748], pp. 108, 109).—Report is made of cases of stiff lamb disease observed in Michigan during the spring of 1939, when losses from this affection were very heavy—some farmers having reported loss of almost 30 percent of the lamb crop. The findings have led the author to conclude that the condition should be prevented by supplying palatable concentrated mixed feed to the lambs rather than allowing them to eat large quantities of hay.

Hog cholera immunization in pigs on low vitamin-B-complex intake, E. H. HUGHES and H. S. CAMERON. (Univ. Calif.). (*Jour. Amer. Vet. Med. Assoc.*, 95 (1939), No. [748], pp. 106, 107).—The experiments reported, although conducted with but few animals, indicated that the immunity produced by serum and virus in pigs on a low vitamin B complex intake was solid where other conditions were satisfactory.

Swine dysentery and Salmonella, W. L. HINDMARSH, D. F. STEWART, and L. HART (*Austral. Vet. Jour.*, 15 (1939), No. 1, pp. 27-30).—Serological evidence presented by the authors indicates that swine dysentery is not due to an infection by *S. cholerae-suis kunsendorf*.

An intermediate host for the swine influenza virus, R. E. SHOPS (*Science*, 89 (1939), No. 2315, pp. 441, 442).—It is pointed out that swine influenza is a disease in which two infectious agents, one a virus and the other a bacterium, are etiologically essential, and that there is no satisfactory explanation of how or where the disease persists during the 8 or 9 mo. elapsing between the yearly epizootics. While the bacterial component of the etiological complex, *Hemo-*

philus influenzae suis, can persist apparently indefinitely in the upper respiratory tracts of some recovered swine, similar persistence of the virus cannot be demonstrated. The origin or source of swine influenza virus responsible for fresh epizootics each autumn has remained obscure, and it is with the epidemiology of these first cases that the experiments here briefly outlined are concerned. The findings are tentatively interpreted in the following way: "Lungworm larvae from pigs with swine influenza harbor swine influenza virus throughout their development both in their intermediate host, the earthworm, and in their definitive host, the swine. The virus apparently lies latent within the lungworm after the parasite has finally migrated to the swine respiratory tract and is only liberated or activated to cause infection when a provocative stimulus is applied. In the experiments just outlined multiple intramuscular injections of *H. influenzae suis* are believed to have supplied the provocative stimulus. *H. influenzae suis* does not, however, appear to be specific or requisite as the provocative agent because, in a preliminary experiment, a single intrapleural injection of calcium chloride solution has served equally well in provoking the swine influenza virus infection."

Quantitative studies on the effect of heat on trichina (*Trichinella spiralis*) larvae, G. F. OTTO and E. ABBAMS (*Amer. Jour. Hyg.*, 29 (1939), No. 3, Sect. D, pp. 115-120).—The experiments reported support previous work in indicating that trichina larvae are not injured by temperatures which could be tolerated by the host, and verify the work of Ransom and Schwartz (*E. S. R.*, 41, p. 684) that 55° C. is the minimal temperature which quickly kills practically all larvae. It is concluded that the Federal requirement of 137° F. (58.3° C.) in the heat-processing of pork offers an adequate margin of safety.

Sulphonamide treatment of facial sinus infection in the horse, J. F. MACDONALD (*Vet. Rec.*, 51 (1939), No. 20, p. 638).—This is a case report of a facial sinus infection of a 6-year-old gelding that was relieved by administration of 30 cc. of a 20 percent solution of sulphonamide subcutaneously daily for 10 days.

Moldy corn poisoning (leucoencephalomalacia) in horses with history of previous attack as well as recovery from virus encephalomyelitis, H. E. BIESTER and L. H. SCHWARTZ. (Iowa State Col.). (*North Amer. Vet.*, 20 (1939), No. 6, pp. 17-19, figs. 2).—A case report of moldy corn poisoning in Iowa.

Notes on the New England outbreak of equine encephalomyelitis, R. RANDALL ([*War Dept. U. S.*], *Off. Surg. Gen., Vet. Bul.*, 33 (1939), No. 2, pp. 87-95).—A brief summary is given of some of the available epidemiological data on equine encephalomyelitis as met with in New England, where its spread through human beings has occurred, as reported by Fothergill et al. (*E. S. R.*, 30, p. 397).

The causative agent of infectious equine encephalomyelitis in Venezuela, V. KUBES and F. A. RÍOS (*Science*, 90 (1939), No. 2323, pp. 20, 21).—Report is made of a study of the causative agent of infectious equine encephalomyelitis conducted at the Laboratories of Veterinary Bacteriology and Parasitology of Venezuela. From the comparative researches conducted both in vivo and in vitro, it is concluded that "the Venezuelan encephalomyelitic virus is wholly different both from the American western virus and from the Argentine virus, with which it has no immunobiological connection; that it also differs immunobiologically from the American eastern strain virus, with which, however, it has some connection on account of its high virulence, pathogenicity, etc.; that the immunizing power of the protective vaccine made from autochthonous virus surpasses by far that of the American bivalent vaccine, prepared from both eastern and western viruses; [and] that the Venezuelan encephalomyelitic serum neutralizes the corresponding specific virus, not only in vivo, but also in vitro."

Transmission of encephalomyelitis in the horse and possible vectors in the human being, J. S. SIMMONS (*New England Jour. Med.*, 220 (1939), No. 23, pp. 956-958).

"Secondary" disease occurring subsequent to infectious equine encephalomyelitis, M. S. SHAHAN, L. T. GLITNER, C. L. DAVIS, and W. T. HUFFMAN. (U. S. D. A.). (*Vet. Med.*, 34 (1939), No. 6, pp. 354-358, fig. 1).—A brief clinical, epizootological, and pathological description is given of the secondary disease which follows infectious equine encephalomyelitis as reported upon by Madsden (El. S. R., 73, p. 108) and Marsh (El. S. R., 78, p. 108). Attempts to produce the disease by inoculation of laboratory animals and horses with tissues from typical clinical or recovered cases were unsuccessful. One of several normal horses injected with encephalomyelitis antiserum developed mild, but apparently typical, clinical evidence of the disease.

Present status of equine encephalomyelitis and its control, B. M. LYON (*Cornell Vet.*, 29 (1939), No. 2, pp. 198-216).—A practical summary of the present status of knowledge of this serious disease. It is pointed out that the vaccine produced by Wyckoff and associates from the diseased chicken embryo, accounts of which have been previously noted (El. S. R., 80, pp. 254, 255), has rendered the diseased horse brain vaccine obsolete because of the greatly increased protection which it induces. "This new 'chick' vaccine has consistently demonstrated 100 percent protection in horses against direct intracerebral virus exposure which killed not only all unvaccinated horses but likewise those vaccinated with the diseased horse brain vaccine. Protection established in horses by 2 doses of the chick vaccine is still complete at the end of 6 mo. against intracerebral virus exposure which is fatal to all unvaccinated horses. From a single dose, horses are temporarily protected by the seventh day following administration but may become infected prior to the seventh day from both natural and artificial exposure. The immunity acquired from a single injection is of short duration, and within 2 mo. animals so vaccinated again become susceptible and succumb to intracerebral exposure as readily as those unvaccinated. Field results with the new chick vaccine during 1938, following the use of well over 1,500,000 doses, correspond directly with the results of experimental tests. The chick vaccine was shown to be a relatively [stable] product at refrigeration temperature but much less so at higher temperatures, thus showing the necessity of constant refrigeration."

Recently acquired knowledge concerning equine encephalomyelitis and its relationship to the problem of control, W. S. GOCHENOUR (*North Amer. Vet.*, 20 (1939), No. 6, pp. 20-25, 26).

Sulfanilamide in the treatment of infectious anemia, W. S. GOCHENOUR, C. D. STEIN, and O. L. OSTERN. (U. S. D. A.). (*Vet. Med.*, 34 (1939), No. 7, pp. 424-430, figs. 2).—A report is made of tests to determine the action of sulfanilamide on normal horses, the effect of large doses of sulfanilamide, and the effect of sodium sulfanilyl sulfanilate.

Studies upon *Strongylus vulgaris*.—I, The incidence of *Strongylus vulgaris* in mid-continental North America and the reaction of the infested ceca, J. H. WHITLOCK and E. E. LEASURE. (Kans. Expt. Sta.). (*Amer. Jour. Hyg.*, 29 (1939), No. 3, Sect. D, pp. 83-87).—It was found in a series of observations upon 174 horses killed at a meat packing house in midwestern North America that 84 percent were infested with *S. vulgaris* in the cecum. Twenty percent of the horses had infestations which were probably extremely harmful to the host.

Treatment of trichostrongylosis in foals, D. W. BAKER, A. G. DANKS, and J. W. BRITTON (*Cornell Vet.*, 29 (1939), No. 2, p. 238).—Report is made of the

success in treating *Trichostrongylus axei* by use of a solution consisting of 1 percent of copper sulfate and 1 percent of nicotine sulfate. From 300 to 325 cc. was administered through a stomach tube to foals that had been starved for 12 hr. No toxic effects of any sort were noted in any of the foals receiving the treatment, and it appears that horses tolerate this dose of copper sulfate-nicotine sulfate mixture well.

Studies on the transmission of *Dirofilaria immitis* in Massachusetts, J. H. PHILLIPS (*Amer. Jour. Hyg.*, 29 (1939), No. 3, Sect. D, pp. 121-129, figs. 4).—The author found that the transmission of heartworm in the dog at Boston, Mass., was linked with six species of mosquitoes (*Anopheles punctipennis*, the common malarial mosquito, *Aedes excrucians*, *A. cinereus*, *A. triseriatus*, and *Culex territans*). "Fleas did not appear to be vectors of *D. immitis*. Mosquitoes do not develop immunity to reinfection with *D. immitis*. Reinfection was observed in *Anopheles punctipennis*, *Aedes cinereus*, and *A. triseriatus*. Stableflies (*Stomoxys calcitrans*) ingest microfilariae when feeding on infected dogs. It is problematical whether they are susceptible hosts."

On the relationship between "Lahore canine fever" and "tick fever" of dogs due to *P[iroplasma] gibsoni* infection, with observations on their pathology and haemocytology, J. F. SHIRLAW (*Indian Jour. Vet. Sci. and Anim. Husband.*, 8 (1938), No. 4, pp. 293-316, pls. 4, figs. 7).—A contribution from the Imperial Veterinary Research Institute, Mukteswar-Kumaun.

Leptospirosis in dogs, W. S. MONLUX (*Cornell Vet.*, 29 (1939), No. 2, pp. 217-221).—In reporting upon this European disease of the dog, which has appeared in the United States in the last several years, it is pointed out that vaccines have been used quite successfully in immunizing against the leptospiral infection.

A preliminary report on the use of nicotinic acid in the treatment of fuso-spirochetal disease of dogs, M. L. MORRIS and C. E. FRANKLIN (*North Amer. Vet.*, 20 (1939), No. 6, pp. 31, 32, 33).—Nicotinic acid, which has recently proved of value in the treatment of canine blacktongue, now appears to be of value in the treatment of Vincent's disease in the dog.

Critical tests of iso-amyl-ortho-cresol as an anthelmintic for the removal of tapeworms from dogs, A. C. JERSTAD. (U. S. D. A.). (*North Amer. Vet.*, 20 (1939), No. 6, pp. 35-37, 38).—Experiments reported have led to the conclusion that "isoamyl-o-cresol cannot be regarded as an effective agent for the removal of *Dipylidium caninum* of the dog. Isoamyl-o-cresol is not effective for the removal of *Taenia pisiformis*, *Ancylostoma caninum*, and *Trichuris vulpis*. Isoamyl-o-cresol is more effective against *Toxocara canis* than against other parasites encountered, but it does not compare favorably with standard drugs already in use for the removal of this parasite."

Preliminary notes on a hitherto undescribed poultry disease, Y. S. GRASOVSKY (*Jour. Amer. Vet. Med. Assoc.*, 95 (1939), No. [748], pp. 71, 72, figs. 7).—A description is given of a disease which appeared among young Rhode Island Red pullets and occasionally hens of the same breed on a large poultry farm in Palestine. While resembling the infectious purulent enteropropen-triculitis studied at the North Carolina Experiment Station by Kaupp and his associates (*E. S. R.*, 60, p. 375), well-defined differences were detected.

A pathogenic *Trichomonas* from the upper digestive tract of chickens, N. D. LEVINE and C. A. BRANDLEY. (*Univ. Ill.*). (*Jour. Amer. Vet. Med. Assoc.*, 95 (1939), No. [748], pp. 77, 78, figs. 2).—A description is given of an affection of the upper digestive tract of chickens associated with *Trichomonas*. The gross pathological lesions observed in naturally affected chickens resemble the trichomonad lesions encountered in pigeons and turkeys. The morphology of

and preliminary animal exposure experiments conducted with the causative *Trichomonas* indicate that it may be a strain of *T. columbae*.

Immunisation of birds against fowl pox and pigeon pox, respectively, with viruses propagated on the chorio-allantoic membrane of the developing egg., R. EL GLOVER (*Jour. Compar. Pathol. and Ther.*, 52 (1939), No. 1, pp. 29-46).—Report is made of work conducted with a strain of pigeon pox virus that has been maintained on the chorioallantoic membrane of the hen's egg for 50 generations. "The virus has become slightly attenuated for the pigeon but induces good dermal lesions in the fowl. It shows no signs of enhanced virulence for poultry. Similarly, a fully virulent fowl pox strain has been carried through 38 generations. It still fails to induce lesions in the pigeon and shows some evidence of attenuation for the fowl. Membranes infected with pigeon virus can be stored in broth at a temperature of 0° to 4° C. There is a gradual loss in infectivity, but lesions are still obtainable in the egg and in the pigeon after 380 days. Fowl virus is also relatively stable under similar conditions. Pigeons which have received a single dose of egg membrane virus by the intradermal, intraperitoneal, or intravenous routes show a fairly durable immunity which can be reinforced by a second dose of virus. The subcutaneous route is less effective. In fowls the intradermal application of the egg virus appears to be as satisfactory as natural virus for the immunization of the fowl, but the immunity shows signs of waning after about 6 mo. The immunity can be reinforced by a second injection of pigeon or fowl virus given intravenously or intraperitoneally. There is a slight indication that fowl virus is the more effective."

On the nature of the agent causing leucosis in fowls, K. G. STERN and A. KIRSCHBAUM (*Science*, 89 (1939), No. 2322, pp. 610, 611, fig. 1).—The studies of the virus of fowl leucosis here reported upon have led to the conclusion that with respect to its chemical and physical properties the material described resembles the causative agent of the Rous chicken tumor I, reported upon by K. G. Stern and F. Duran-Beynals,* and also the macromolecular material isolated by A. Claude† from normal chick embryos. In contrast to the virus proteins isolated by Stanley and others (El. S. R., 81, p. 52) from plants, these materials do not represent pure nucleoproteins but much more complex chemical structures of the type encountered in the analysis of protoplasm.

Failure of wheat germ oil to prevent lymphomatosis in chickens, L. W. TAYLOR and K. B. DEOME, (Univ. Calif.). (*Jour. Amer. Vet. Med. Assoc.*, 95 (1939), No. [748], pp. 75-76).—Data presented, the details of which are given in tables, are considered to show clearly that under the conditions of the experiment the feeding of wheat-germ oil had no appreciable effect on the incidence, type, or age of onset of lymphomatosis. "In this experiment the genetic constitution of the stock was responsible for the differences observed in the incidence of lymphomatosis. This conclusion is in agreement with previous work on this flock, wherein the principal identifiable variable associated with the disease was of genetic nature." A list is given of 11 references to the literature.

AGRICULTURAL ENGINEERING

[Agricultural engineering investigations at the Idaho Station] (*Idaho Sta. Bul.* 229 (1939), pp. 20-22).—The report notes briefly work on drainage of irrigated lands and methods of reducing canal losses, use of the press-type furrow drill in dry farming, harvesting equipment for beans and peas and for

* *Science*, 89 (1939), No. 2322, pp. 609, 610, fig. 1.

† *Soc. Expt. Biol. and Med. Proc.*, 39 (1939), No. 2, pp. 398-403, fig. 1.

wheat, the commercial type beet combine harvester, and the bed method of seedbed preparation and cultivation.

[Agricultural engineering investigations of the Indiana Station] (*Indiana Sta. Rpt. 1938, pp. 15-19, 20-26, figs. 9*).—This report contains notes on the adaptation of the Purdue plow trash shield to 4 more plows, making the device now available for 33 plows, by R. H. Wileman; successful trial of a home-made subsurface shaver for killing out Canada thistle and the use of the duck-foot cultivator for control of this weed, by Wileman and O. C. Lee; rubber tires v. steel wheels for tractors and seed-corn drying, both by Wileman; a combined harvester thresher, a study of atmospheric corrosion on wire and wire products, field ensilage harvester, a study of low-pressure pneumatic tires on power-driven manure spreader, and experimental dairy barn, all by I. D. Mayer; poultry house heating, by Mayer and C. W. Carrick; electric heaters for apple washers, wind electric plants, electric pig brooders, and electric dairy water heaters, all by T. E. Hinton and J. M. Fore; use of electric energy in brooding chicks, by Hinton, Fore, and S. Hinners; storage problems in marketing sweetpotatoes, by Hinton, F. C. Gaylord, and J. A. McClintock; precooling fresh fruits in refrigerator cars, by Hinton, K. I. Fawcett, and Gaylord; use of electric illumination for forcing crops in commercial greenhouses, by Hinton and R. B. Withrow, codling moth control with electric traps, by Hinton and G. E. Marshall; use of electric heat in automatic drinking fountains in experimental hog lots, by Hinton, Fore, and C. M. Vestal; and use of electric traps as a possible control for European corn borer and other field crop insects, by Hinton, Fore, and G. A. Ficht.

[Agricultural engineering investigations by the Nebraska Station] (*Nebraska Sta. Rpt. [1938], pp. 5-7*).—This report contains brief notes on use of electric power on Nebraska farms, cooling milk on the farm by a "dry" type portable cabinet, mechanical equipment needed in the eradication of bindweed, adaptability of electric hotbeds to farm use, adaptation of insulated electric brooders in uninsulated poultry houses, and methods and equipment for storing eggs under controlled temperature and humidity.

Ground water resources, K. ENGLEB and D. G. CARTER. (Ark. Expt. Sta. et al.). (*Agr. Engin., 20 (1939), No. 7, pp. 263, 264, 266, figs. 3*).—In a 10-yr. study of the ground water conditions in the Grand Prairie of Arkansas, the irrigation water requirement amounted to approximately 20 acre-in. per year, on an average of 124,000 acres of rice per year, 90 percent of which was pumped from the Pleistocene sands. The withdrawal of water has resulted in a lowering of the ground water by an average of 0.8 ft. per year. However, the decline varies with seasonal rainfall, acreage, and location. A continuous chart record affords evidence of a gradual and persistent decline of the ground water level and shows annual, seasonal, and daily fluctuations. It is evident that under present conditions the safe yield of the Pleistocene sands is being exceeded each year. Additional research is under way to determine the safe yield and the possibility of developing economical surface supplies of irrigation water.

Watershed and hydrologic studies on the Blacklands experimental watershed, R. W. BAIRD. (U. S. D. A.). (*Agr. Engin., 20 (1939), No. 7, pp. 279-276, figs. 6*).—This is a brief description of the equipment and technic being employed in this U. S. D. A. Soil Conservation Service research project near Waco, Tex.

A study of temperatures under sheet steel roofs, H. GIESSE, W. D. SCOATES, and N. C. IVES. (Iowa Expt. Sta.). (*Agr. Engin., 20 (1939), No. 7, pp. 267-270, figs. 7*).—A brief description is given of the technic and equipment employed in this study.

AGRICULTURAL ECONOMICS

[Investigations in agricultural economics by the Indiana Station, 1938] (*Indiana Sta. Rpt. 1938, pp. 58-61, 79, 80, figs. 2*).—Findings not previously noted are reported as follows: Additional findings (El. S. R., 79, p. 691) by J. C. Bottum in studies of farm organization in central Indiana and combine harvester-thresher costs; by El. C. Young on cost of winter broilers; and by O. G. Lloyd and J. R. Hays on the relative income on farms operated under different types of tenure; and general findings by L. S. Robertson as to the effects of size of farm, yields, prices, amount of livestock, and returns per \$1 worth of feed fed on labor income on northwestern Indiana farms; by Robertson, Young, Hays, and M. O. Pence on the adjustments needed on 213 Knox County farms; by T. R. Cowden as to use and costs of operation of trucks on 262 farms; by Robertson and M. G. Smith as to costs, labor requirements, and returns in 1937 on 52 farms growing peppermint; and by El. R. Menefee as to the buying and the possibilities of retailing eggs on the grade basis.

Economic studies of vegetable farming in New York.—VI, Production and marketing of celery, 1936, J. N. EFFERSON (*[New York] Cornell Sta. Bul. 715 (1939), pp. 62, figs. 10*).—Continuing this series (El. S. R., 80, p. 408), cost records were obtained from 100 enterprises in Wayne County in the northwest part of the State and 13 in Orange County in the southeastern part. The areas are described, and an analysis is made of the methods and costs of production and marketing, the returns, the factors affecting costs and returns, and labor income. A table shows the business-analysis factors in 1936 for the muck farms studied in Wayne County.

In Wayne County the farms with large acreages of celery had the lower costs per crate and per acre and higher returns for labor. Those with high yields had higher costs per acre but lower costs per crate. Large acreages and high yields combined gave the lowest costs and highest returns for labor. The average returns above all expenses per acre and per crate were \$12 and 4 ct. for late celery in Wayne County, \$448 and \$1.14 for sash- or canvas-covered celery, and \$108 and 28 ct. for early field-grown celery in Orange County. The average returns per hour for labor were 28 ct., 83 ct., and 55 ct., respectively.

Farm practices and management in central Pennsylvania, J. El. McCOMB (*Pennsylvania Sta. Bul. 379 (1939), pp. [2]+101, figs. 15*).—This bulletin is based on 1,262 farm management records—from 123 to 281 per year—taken on Centre County farms and covering the years July 1, 1930, to June 30, 1937. The history, population, topography, climate, soils, transportation facilities, and markets of the area are described. An analysis is made of the capital, receipts, expenses, and profits; size of farm; crop acreages, yields, crop practices, and use of crops; number, value, purchases, and sales of livestock; the dairy, poultry, and swine enterprises; feeding practices; use of automobiles, trucks, and tractors; produce used in the home and farm home conveniences; factors affecting labor income; size of business; labor efficiency; capital turnover; and combination of enterprises on the farm.

The farms averaged approximately 160 acres, with 83.8 acres cropped. The average investment was \$11,442 per farm, the average receipts \$2,363, and the average expenses \$1,641, leaving a farm income of \$722 and a labor income of \$150. Of the total receipts 59 percent was from livestock products, 18 percent from sale of crops, 15 percent from livestock increase, and 7 percent from miscellaneous sources. Products used as part of the family living were valued at \$350 per year per farm. Retail milk marketing was the most profitable type of farming, with special crops second. The higher labor incomes were

made where (1) crop yields were 10 percent or more above the average, (2) 7,500 lb. of milk or more was sold per cow, (3) the production index was 20 percent above the average, (4) 300 or more days of productive work per year were put in, and (5) in the case of dairy farmers where more than 80 percent of the gross receipts were from livestock products. Farmers with less than \$1,500 gross receipts per year rarely made a positive labor income, while those with \$4,500 or more had positive incomes each year. Those with gross returns averaging 12 percent or less of the capital invested did not have plus labor incomes any year, while those with receipts of 24 percent or more of the average capital had plus labor incomes each year.

Farming possibilities in Horry County, South Carolina. O. STEANSON, M. H. SUTHERLAND, and M. C. ROCHESTER. (Coop. U. S. D. A.). (*South Carolina Sta. Bul. 318 (1939)*, pp. 72, figs. 2).—The bulletin describes and discusses the factors affecting agriculture in the county; the past and present farm business organization—land utilization and cropping practices, crop yields, production factors and financial outcome of different crops, production operations and labor requirements, livestock enterprises, farm labor, capital investment, farm income, labor relationship, etc.; and the types of farm organization—family cotton, family tobacco, and large tobacco farms.

The wheat economy. G. E. BRITNELL ([Toronto]: Univ. Toronto Press, 1939, pp. XVI+[1]+259, pls. 3, figs. 4).—This volume deals with the prairie provinces of Canada, especially Saskatchewan. The geographical background, railways and population, the distributing structure, and provincial and municipal institutions are described. The agricultural settlement and expansion of the area, economic farm unit, land tenure, production trends, gross and net farm income, farm indebtedness, farm relief, farm standards of living, and rehabilitation of the area are discussed.

Quality of North Carolina cotton 1928-1936. W. B. LANHAM, G. R. SMITH, and R. H. RAPEL. (Coop. U. S. D. A.). (*North Carolina Sta. Bul. 323 (1939)*, pp. 51, figs. 16).—Samples were obtained for an average of 55 gins each year, representing 5 to 9 percent of the cotton produced in the State. An analysis for the 4 general grade and staple districts of the State and 12 subdistricts is made and compared with the United States as to staple length and grade. Prices and premiums and discounts on different grades and staple lengths and the consumption of cotton in the State are discussed.

During the period the average staple length of cotton produced in the State increased from 14.69 sixteenths of an inch to 16.07 sixteenths of an inch as compared with from 15.18 sixteenths of an inch to 15.77 sixteenths of an inch for the United States. In 1936 13 percent of the cotton in the State had a staple length of less than $1\frac{1}{16}$ in. and 85 percent $1\frac{1}{16}$ to $1\frac{1}{8}$ in. as compared with 80 percent and 19 percent, respectively, in 1928. Little or no progress was made in improving grades. The proportion of $\frac{3}{8}$ -in. cotton increased gradually to about January 15 then decreased, while that of 1-in. and longer cotton decreased to about January 15 and then increased. The percentage of $1\frac{1}{8}$ -in. and shorter cotton remained almost constant throughout the season. The grade decreased rapidly as the season advanced. The production in the State ranged from 579,300 bales in 1935 to 869,300 in 1928, averaging 711,800 bales, and the consumption in the State from 1,249,700 bales in 1934 to 2,021,100 bales in 1936, averaging 1,467,700 bales. Prices to growers reflected only 18.8 percent of the central market premiums for grades above Middling and 59.1 percent of those for staple lengths longer than $\frac{3}{8}$ in. Discounts for lower grades averaged 64.4 and 14.9 percent for shorter staples.

Idaho potato has strong competition (*Idaho Sta. Bul.* 229 (1939), pp. 23, 24).—Included are findings as to relative prices in Chicago, 1929-37, of Idaho Russet and Colorado Red McClure potatoes, the range of the price spreads, and the relative volumes of the two varieties marketed.

Joint correlation applied to the quality and price of McIntosh apples, J. R. RABURN ([*New York*] *Cornell Sta. Mem.* 220 (1939), pp. 44, figs. 14).—This study was made with a view to developing methods of partial joint (surface) curvilinear correlation. It is based on records of quality of and prices received for 98 lots of McIntosh apples sold to jobbers on the Washington Street market, 159 lots sold by jobbers on the Washington Street, Wallabout, and Harlem markets, and 47 lots sold by farmers on the Wallabout farmers' market of New York City from October 9 to November 28, 1934. The three groups are studied separately. Joint curvilinear correlations were made using price, average diameter, percentages of serious and not-serious defects, indexes of variation in diameter, facing for serious and not-serious defects, color and facing for color, grade and size marked, and size of container. The profitableness of strict grading for serious and not-serious defects and diameter, the actual market premiums for quality, and the standards set up by grading regulations are discussed.

Serious and not-serious defects affected prices jointly, the influence of each depending on the proportion of the other. Jobbers paid premiums for only a limited amount of quality with respect to defects. Retailers paid higher premiums for quality and discounted defective apples more than jobbers. On farmers' markets serious defects reduced prices about the same as on jobbers' markets, but not-serious defects were not important. Retailers paid less than jobbers for increase in average diameter from 2.6 to 2.8 in. when few defects were present and more when the defects were numerous. Where there were few defects retailers paid more for apples averaging 2.8 in. than those averaging 3 in. in diameter. Retailers discounted small diameters less when buying from farmers than when buying from jobbers. Large diameters were discounted more unless many defects were present. Proportion of serious and not-serious defects and average diameter accounted for 42.9 percent of the variation in the price of lots sold to jobbers and 56.9 in those sold by jobbers. Prices were adjusted to quality more closely in lots sold by jobbers to retailers than in those sold to jobbers by wholesalers. Facing for defects raised prices of the lots with many defects about the same on the wholesale market as on the jobbers' markets. Facing for not-serious defects raised prices more than for serious defects. Jobbers paid slightly more than retailers for extra color and facing for color. The prices paid by retailers for extra color and color facing were more for lots marked as high grade and large size. A small premium was paid for large "bushel" crates, but it was not in proportion to the larger volume. "If the premiums for quality paid by retailers had been received by the producer, it might have been profitable to reduce the proportion of not-serious defects from 30 to 10 percent when few serious defects were present, to reduce the proportion of serious defects to less than 10 percent when only 10 percent of not-serious defects were present, [and] to grade lots of small apples with many defects (index of defects 50 and average diameter 2.6) more closely on the basis of average diameter."

The author states that both the maximum and minimum size of apples should be marked on crates, the grading regulations should limit the proportion of not-serious defects permissible in the Utility grade, and that apples with less than 67 percent of the skin "a good red characteristic of the variety" should not be permitted in the United States Fancy grade, nor those with less than 33 percent in the United States No. 1 grade.

Wool and the wool trade, A. H. GARSIDE (*New York: Frederick A. Stokes Co., 1939, pp. XV+331, [pls. 23, figs. 3]*).—The apparel wool trade in the United States is discussed, particularly from the standpoint of the New York Wool Top Exchange. The first chapters, dealing with the size of the industry, production, scouring, shrinkage, grading, etc., cover both apparel and carpet wool.

Proceedings of the Conference on Markets for Western Farm Products (Winnipeg: Govt., 1938, pp. 333, figs. 39).—The following leading papers presented at the conference arranged by the Province of Manitoba and held at Winnipeg December 12-15, 1938, are included: Western Agriculture in the Canadian Economy, by W. A. Mackintosh (pp. 8-18); An Appraisal of the World Wheat Situation, by C. F. Wilson (pp. 18-60); An Appraisal of the Canadian Wheat Situation, by H. L. Griffin (pp. 60-81); European Wheat Requirements and Policies, by L. A. Wheeler (pp. 81-90), and The Wheat Problem of the United States, by R. M. Evans (pp. 90-95) (both U. S. D. A.); Export Markets for Canadian Flour, by C. H. G. Short (pp. 95-110); The Wheat Industry of Australia, by P. F. Bredt (pp. 110-114); The Wheat Industry of the Argentine, by D. A. MacGibbon (pp. 115-119); Monetary Policy in Relation to Farm Income, by A. R. Uppgren (pp. 131-143) (Univ. Minn.); What the Price of Wheat Means to Western Farmers, by E. C. Hope (pp. 146-158); A Submission by the Calgary Board of Trade, by C. Pierce (pp. 158-161); Relationship of Value of Wheat Production to Business Submitted by Regina Board of Trade, by R. L. Christopherson (pp. 162-165); Western Agricultural Zones and Their Adaptability to Various Types of Farming, by J. H. Ellis, J. Mitchell, and F. A. Wyatt (pp. 165-173); The General Utilization of Land in Manitoba and the Agricultural Use Made of the Cultivated Lands, by J. H. Ellis (pp. 173-193); Saskatchewan Soil Zones, by J. Mitchell (pp. 194-196); Western Agricultural Zones and Their Adaptability to Various Types of Farming, by F. A. Wyatt (pp. 196-201); The Possibilities of Shifting From Wheat Growing to Other Types of Farming in Western Canada and the Implications of Such Changes, by J. B. Taggart (pp. 201-213); The Barley Industry of Western Canada, by A. T. Elders (pp. 213-234); The Honey Industry and Markets for Honey, by L. T. Floyd (pp. 246-249), E. Braun (pp. 249-252), and J. W. Braithwaite (pp. 252-257); Marketing Problems Facing the Fresh Water Fisheries in General and Those of Manitoba in Particular, by W. A. Found (pp. 257-265); The Problem of Export Markets for Canadian Cattle, by A. M. Shaw (pp. 265-275); The Problem of Export Markets for Canadian Hogs, by L. W. Pearsall (pp. 275-284); Markets for Creamery Butter, by G. W. Tovell (pp. 292-308); and The Western Poultry Industry and Its Marketing Problem, by W. A. Landreth (pp. 309-314).

Milk cartage in the Southwick-Agawam area of the Springfield milkshed, A. A. BROWN and J. E. DONLEY (*Massachusetts Sta. Bul. 363 (1939), pp. 26, figs. 11*).—This is a study made of 12 milk routes serving 112 producers and supplying 12 dealers in January 1935. Tables show for May and December 1935 for the 7 largest routes the size of loads, stops per load, total miles traveled, collection per miles traveled, pounds of milk per mile, and miles traveled per stop of total mileage and collection mileage. Other tables show the rates paid by producers and producers' cash costs of cartage on the 12 routes, the seasonal variations between May and December in income and load in the most variable and least variable groups, and other data. A reorganization of 12 of the original routes into 4 routes is outlined.

Under the original routes the average size of load ranged from 344 to 3,064 lb., the number of producers per load from 2 to 28, and the rates (11 rates) from 20 to over 46½ ct. per 100 lb., the most common rate being 35 ct. Under a suggested plan the total route mileage is reduced from 270 to 167 miles, the actual collection mileage from 142 to 98 miles, and deadheading from 128 to 60 miles, and the

average per 100 lb. cost from 33.4 ct. to 24.2 ct. Five rate zones with rates per 100 lb. of 15 to 35 ct., with an additional 5 ct. for off-route producers, are suggested. The most common rate under this plan is 20 to 25 ct. It is estimated that the lower cartage rates would save producers an average of \$26 per year.

Organizing a farmers' cooperative, S. D. SANDERS (*Farm Credit Admin.* [U. S.], *Coop. Div., Cir. C-108* (1938), pp. I+42, fig. 1).—This popular circular gives information and suggestions regarding the various steps in the organization of a cooperative association. Suggested organization forms and the Capper-Volstead Act are included in appendixes.

Financial history of Ohio farmer owned elevators for the period 1928-1938, B. A. WALLACE (*Ohio State Univ., Dept. Rural Econ. Mimeog. Bul. 120* (1939), pp. [2]+28, figs. 2).—This is a continuation of the series (E. S. R., 78, p. 870).

Operations of cooperative grain elevators in Kansas and Oklahoma, H. HEDGES. (Coop. Kans. State Col. and Okla. A. and M. Col.). (*Farm Credit Admin.* [U. S.], *Coop. Div., Bul. 30* (1939), pp. IV+64, figs. 20).—The objectives of this study were to determine the financial status of the cooperative grain elevators in Kansas and Oklahoma, to obtain information on their operating practices and problems, to learn more of the factors influencing income and business success, and to provide definite conclusions regarding operation and membership. Data were assembled for the crop years 1931-32 to 1935-36 annually, chiefly from annual reports of the associations, in regard to financial status, operating practices, and results of a large number of farmers' grain elevators in two States, and for the crop year 1936-37 from a survey by the Farm Credit Administration of all farmers' cooperative associations in the United States. The importance of local cooperative grain marketing, financial status, operating results and the factors influencing such results, membership and membership patronage and their relations to business volume, capital structure and net income, grain volume and side lines as operating factors, and unit costs of operations are discussed.

Accounting procedure for cooperative grain elevators, E. B. BALLOW (*Farm Credit Admin.* [U. S.], *Div. Res., Bul. 28* (1938), pp. IV+221).—A method of bookkeeping procedure for operating accounting systems is set forth in detail. It deals largely with a classification of accounts needed and a definition of the items that may be assigned as debits and credits.

A manual of farm law, N. H. MOLLER (*London: Stevens & Sons and Sweet & Maxwell, 1938, pp. XLIV+528*).—Legal material covering the activities of farmers in England is brought together.

[Farm management and appraisal of rural property] (*Jour. Amer. Soc. Farm Mgrs. and Rural Appraisers, 2* (1938), Nos. 1. pp. 3-38, 56, figs. 3; 2, pp. 59-84, figs. 2).—Included are articles as follows:

No. 1.—The English System of Regulating Landlord-Tenant Relations, by K. Brandt (pp. 3-14); The Past Performance of Two Price Averages, by E. E. McAnelly (pp. 15-19); Perpendicular Diversification, by D. H. Doane (pp. 20-23); How Much Credit Is Too Much Debt for the Farmer? by R. M. Green (pp. 24-26) (U. S. D. A.); Farm Accounting From the Viewpoint of the Farm Manager, by M. M. Winkler (pp. 27-29); Verification of Income and Expense Items, by E. J. McConnell (pp. 30-35); and Factors Influencing Farm Lending Experience in Coles and the Six Adjoining Counties, Illinois, 1917-1933, by J. Ackerman (pp. 36-38) (Univ. Ill.).

No. 2.—Debt-Carrying Capacity of Farm Property in Relation to Cash Income, by W. H. Pine (pp. 59-63) (Kans. State Col.); The Co-ordination of Farm Management with Servicing of Farms and Loans, by F. W. Reinoebl (pp.

64-72); Establishing the Income Capitalization Value, by E. R. Morrison (pp. 73-76); Comparative Adjustments in the American Rural Appraisal System, by H. E. Stalcup (pp. 77-80); and Soil Texture and the Appraiser, by H. Pike (pp. 81-84) (Iowa State Col.).

Farm mortgage loan experience in central Montana: A study of the important factors associated with good or bad mortgage loan experience, P. S. ECKERT and O. H. MAUGHAN (*Montana Sta. Bul. 372 (1939), pp. 39, figs. 14*).—This study of factors associated with mortgage loan experience is based on an analysis of the loans on 529 farms made prior to 1933 in Fergus and Judith Basin Counties, and a sample area comprising parts of Cascade, Chouteau, Liberty, Pondera, Teton, and Toole Counties. General information about the area is included.

Seventy percent of the loans made from 1911-20 and 41 percent of those made from 1911-33 had been foreclosed by the end of 1937. Twenty-one percent of the loans on livestock ranches and 44 percent of those on wheat farms had been foreclosed, the losses per \$100 loaned being \$5.22 and \$14.89, respectively. The percentages of foreclosures as affected by different factors were: 22 percent on first-class farm land and 58 percent on fourth-class land; 8 percent on farms with wheat yields averaging 20 bu. or more per acre and 61 percent on those with yields of less than 5 bu.; 8 percent on farms classed as excellent on the basis of size and condition of buildings and other visible evidence as to amount and condition of farm capital as compared with 87 percent on farms where improvements were negligible; 16 percent on wheat farms over 1,000 acres or more cultivated and 59 percent where there were less than 200 cultivated acres; 10 percent on wheat farms with \$10,000 to \$20,000 productivity value and 63 percent where the productivity value was less than \$1,000; 80 percent where loans were less than 20 percent of the appraised value and 44 percent where they were over 45 percent of the appraised value; 34 percent where the taxes were less than 3 percent of the productivity value and 52 percent where they were 9 percent or over; less than 18 percent on farms using electricity or telephone as compared with 40 percent without such services; 26 percent on loans of less than \$5 per acre of total acreage, 42 percent for loans of \$5 to \$10 per acre, and 49 percent for loans of \$20 or more per acre; and 12 percent where loans were less than \$10 per cultivated acre and 49 percent where they were \$25 or more.

The sixth annual report of the Farm Credit Administration, 1938 (*Farm Credit Admin. [U. S.] Ann. Rpt., 6 (1938), pp. [VI] + 238, figs. 19*).—This is the report submitted to the House of Representatives. It covers the Federal land banks, the National farm loan associations, production credit corporations and associations, Federal intermediate banks, Land Bank Commissioner loans, emergency crop and feed loan offices, Agricultural Credit Corporation stock purchase loans, joint stock land banks, etc., and the operations of the several divisions of the Administration.

Foreign Agriculture, [June 1939] (*U. S. Dept. Agr., Foreign Agr. Serv., Foreign Agr., 3 (1939), No. 6, pp. 219-278, figs. 10*).—Included are articles on The Market for American Tobacco in the Netherlands, by P. G. Minneman (pp. 221-262), and Recent Japanese Agricultural Policies, by O. L. Dawson and W. Ladejinsky (pp. 263-274), and notes on recent developments in foreign agricultural policy as follows: Peruvian Institute of Agricultural Studies, Egypt enacts law for the reduction of mortgage debts, and Swiss-Rumanian wheat purchase agreement.

The Netherlands state policy of price regulation with regard to the products of animal husbandry since 1932 [trans. title], H. von OERTZEN

(*Ber. Landw. Reichsmin. Ernähr. u. Landw.* [Germany], n. ser., 24 (1939), No. 1, pp. 49-120; *Eng., Fr., Ital., Span. abs.*, pp. 114-118).—The policy of the government and the results obtained are discussed.

Prices of farms in Finland in 1933-1938 [trans. title], L. SEPILÄ (*Acta Agr. Fenn.*, No. 40 (1939), pp. [1]+87, figs. 22; *Eng. abs.*, pp. 84-86).—This study is based on 3,510 forced sales 1933-36 and 339 voluntary sales 1935-38. Auction prices fell during the period 1933-36, while the index of voluntary sales prices rose from 100 in 1935 to 116, 134, and 143, respectively, in the following 3 yr.

Crops and Markets, [May-June 1939] (*U. S. Dept. Agr., Crops and Markets*, 16 (1939), Nos. 5, pp. 89-104, fig. 1; 6, pp. 105-124, figs. 2).—Included are crop and market reports of the usual types.

Ohio agricultural statistics, 1937, G. S. RAY, O. M. FROST, and P. P. WALLRABENSTEIN. (Coop. U. S. D. A.). (*Ohio Sta. Bul.* 602 (1939), pp. 59, fig. 1).—This bulletin continues the series (*El. S. R.*, 79, p. 703).

Preliminary report: Statistical analysis of the annual average f. o. b. prices of California canned asparagus, 1925-26 to 1938-39, H. R. WELLMAN (*California Sta.*, 1939, pp. [1]+6, figs. 2).—Tables and charts are included showing the relations of shipments, indexes of nonagricultural income in the United States, and indexes of income of industrial workers to the f. o. b. prices of California canned asparagus.

Statistical analysis of the annual average f. o. b. prices of canned clingstone peaches, 1924-25 to 1938-39, H. R. WELLMAN (*California Sta. Mimeog. Rpt.* 67 (1939), pp. [1]+9, figs. 3).—For the 15-yr. period a change of 1,000,000 cases in total shipments was accompanied by a change of 16 ct. in the opposite direction in the f. o. b. price, a change of 10 points in the index of nonagricultural income in the United States by a change of 48 ct. per case in the same direction, and a change of 10 points in the adjusted index of prices of competing canned fruits by a change of 25 ct. per case in the same direction.

Oils and fats: Production and international trade, A. BEZZI (*Internat. Inst. Agr. [Roma], Studies Princ. Agr. Prod. World Market*, Nos. 4 (1939), pt. 1, pp. [13]+345, figs. 6; 5, pt. 2, pp. [5]+423, pls. 14).—Continuing this series (*El. S. R.*, 81, p. 444), the production and international trade in oils and fats and the trends therein are described by product and countries. Part 1 deals with vegetable oils and fats and part 2 with those from land and marine animals, including sections on the production and consumption of fats and oils in certain countries and the utilization and prices of oils and fats. Part 1 was edited by I. Grinenco and part 2 by H. Böker (except for the section on fats from land animals, which was prepared by S. Taussig).

RURAL SOCIOLOGY

Rural social-economic planning (*Plan Age*, 4 (1938), No. 6, pp. 149-184).—Papers presented were: The Social Elements in Land Planning, by C. O. Taylor (pp. 149-155); Institutional Adjustments in Land Planning, by W. E. Packard (pp. 156-162); Positive Agricultural Planning, by A. W. Stuart (pp. 163-169); Coordinating Land-Use Programs, by M. S. Eisenhower (pp. 170-176); and Credit as a Factor in Land Planning, by D. R. Rush (pp. 177-184).

A preliminary group classification based on structure, D. SANDESSON. (Cornell Univ.). (*Social Forces*, 17 (1938), No. 2, pp. 196-201).—The leader presents and explains a tentative classification for groups based on structure.

The number of unincorporated places in the United States and their estimated populations, P. H. LANDIS (*Wash. State Col. Res. Studies*, 6 (1938), No. 4, pp. 160-188).—The number of places with 0 to 2,499 population reported

by Bradstreet for the United States reached its climax in 1910 when there were 75,436 places. During the following decade the number decreased 12,668, and during the decade 1920-30 it dropped 6,193. In 1900, 73,882 places were listed; in 1930 there were only 56,575.

Composition and characteristics of the agricultural population in California. G. M. PETERSON (*California Sta. Bul. 630 (1939), pp. 48*).—Of the 135,676 farms listed in the 1930 census of agriculture for California, 10,877 were occupied urban farms, 106,335 occupied rural farms, and 18,464 operated by people who did not live on the farms.

Of the farmer operators 42,511, or nearly one-third of the total, reported that they had worked off the farms in 1929, and 21,929 of them reported that they spent more than 150 days each working off the farm. If 275 days represents full-time employment, then the work off the farm by all farm operators is equivalent to about 25,000 full-time workers. These may be roughly divided into 7,000 working in agriculture and 18,000 working in other industries than agriculture.

In 1929 the largest farms in the State, representing only 2.1 percent of the total number of farms, had 34.6 percent of the total expenditure for hired labor. Farming operations and the activities of people living on farms are becoming so intermingled with other industries and occupations that it is no longer possible to treat agriculture or people living on farms as isolated separate entities. Agricultural policy in the future must consider these complications. Of all the gainfully employed males in California, only 16.5 percent are gainfully employed in agriculture, which as a source of gainful employment is not so important as either trade or manufacturing. Farmers as owners and tenants represent only 6.2 percent of all of the gainfully employed males in the State, whereas persons employed on farms as laborers, managers, and foremen represent 10.3 percent.

There are almost as many native white farm laborers as there are native white farm operators. Native and foreign-born whites constitute 59.5 percent of the farm laborers, Mexicans 20.9, Japanese 7.4, and Filipinos 8.2 percent. The corresponding percentages for farm managers and foremen were for native and foreign-born whites 74.1 percent, Mexicans 3.4, Japanese 19.1, and Filipinos 1.1 percent. Since there are very few Filipino women in the State, Filipinos as a race group in California will decrease in importance. The opposite conditions apply to Japanese and Mexicans, of whom about one-half of the total represented by each race in 1930 were native-born citizens of California. Families of these races with homemakers average 5.12 persons each as compared with 3.7 for white families.

Farm population mobility in selected Montana communities. C. F. KRAENZEL (*Montana Sta. Bul. 371 (1939), pp. 64, figs. 15*).—This study shows that drought period migration conforms to the usual mobility patterns, except that it affects more people. Usual mobility aspects that also characterize drought period migration are the following: (1) Short distance mobility is more frequent than long distance mobility, (2) an exodus out of an area is always accompanied by a countermovement of population into the same area, (3) the older families and population are less migratory than the younger families and population, (4) proportionately more males than females enter the rural areas, and (5) long distance migrants tend to go more frequently to urban than to rural areas and enter urban and industrial occupations more frequently than they enter rural and agricultural occupations. The exodus of some population, in many drought areas, is not likely to be a solution to the existing problems of pressure of population on resources, because the recent

settlement and the similarity of age of the settlers means that the sons and daughters of the first agricultural settlers are only now ready to start farming for themselves. Great Plains communities create an opportunity for the second generation of beginning families to establish themselves in their home communities or nearby. The unusually high past mobility in many Great Plains areas has resulted in little attention being given to the "community" in the lives of people. Only one-third of the families ever resident in the areas of study had lived there for a period of 12 yr. It is believed that in order to achieve a more stable population it is necessary to have a well-established community.

Basic trends of social change in South Dakota.—I, **Population tendencies**, W. F. KUMLIEN (*South Dakota Sta. Bul.* 327 (1939), pp. 58, figs. 58).—South Dakota will have had statehood 50 yr. on November 2, 1939. The total population of the State increased consistently with each decade from 1870 to 1930, but has declined over 20,000 since the later date. The rate in increase declined sharply after 1910. American-born whites, living in the State in 1930, constituted 90.5 percent of the total white population, and 56.5 percent are South Dakota born. In 1890, 15 percent of the State's population was under 5 yr. of age, while only 2.4 percent was 65 or over. By 1930 those under 5 yr. of age had declined to 10.3 percent, while those 65 or over had increased to 5.4 percent. The middle group between 20 and 64 have remained fairly constant during the 50-yr. period.

South Dakota has since 1925 shown a tendency towards a definitely declining crude birth rate, and since 1933 a slightly increasing crude death rate. These trends, together with a virtual cessation of foreign immigrants, and a net loss in native migrants in and out of the State, have resulted in a decline in population first recorded in the State census of 1935. There are strong indications that because of the combination of limiting factors mentioned above which are operating in population growth, South Dakota will soon reach a stationary level.

Social conditions in the delta area, Utah, J. A. GEDDES, C. D. FREDRICKSON, and E. C. BERGESON (*Utah Sta. Bul.* 288 (1939), pp. 93, figs. 16).—The average size of family in the delta area was 4.67; on the poorest or class 3 soils it was 4.95. The State average was 4.19.

The ratio of males : females in the area was 120.46 : 100. In Utah (1930) it was 111.5. The Utah rural farm ratio was 114 : 100. In the delta area there was little excess of males up to 18 yr. of age. From this age on the number of daughters living at home declined much more rapidly than that of sons.

Families living in the area over 20 yr. had farms on the better soils. Proportionately more of the newcomers (those with less than 5 yr. residence) lived on the poor soils. More than two-thirds (67.2 percent) of the cooperator families were farmers at earlier periods of their lives. Laborers constituted 4.8 percent, semiskilled 4, skilled 8.8, business 5.6, and all other occupations 9.6 percent. The annual income and largest worth were greater after coming to the area than earlier, although the farms were smaller. The average education of fathers was 8.5 grades and mothers 9.5 grades.

The total expenditures for family living averaged \$1,421 in the delta area in 1931. After the age of 12, sons spent more for clothing than their fathers, reaching a maximum of nearly twice the fathers' expenditure for the age group 19-24. Daughters over 12 also spent more than their mothers. The husband spent more for clothing than his wife by a margin of 100 to 38. The operation of the automobile cost the average family \$83.26 per year. Eight out of 9 families owned automobiles.

Taxes were paid on 16.6 percent of the land belonging to cooperators. Of the total amount of taxes levied, 20.3 percent was collected (1931). There were no tax levies for health, economic development, or recreation, but small voluntary contributions were made in these fields. The church received the most support both in money and in number of families contributing to voluntary agencies, with an average of \$40.02 to the family.

Few of the 742 area homes reached the minimum requirements set up for adequacy. Nonfarm homes, largely in the villages, met these requirements better than farm homes. The average original cost of the home for the delta area was \$1,638 (1934). The assessor's valuation was \$998. Delta area houses were small, with an average of 4.44 rooms to the house and 0.92 room to the person. The Delta area was lower than certain other Utah villages with respect to percentage of homes with electric lights, iron, and washer. It was also low in running water, kitchen sink, stationary bath, and indoor toilet. Less than two-thirds (60.8 percent) of the homes of the area had electric lights, less than one-third running water, less than one-fourth running hot and cold water, and slightly more than a fifth a bathtub and an indoor toilet. Only 1 home in 15 was centrally heated. Very few refrigerators or electric stoves were found. Less than one-fourth of the homes were in good repair. Over one-half (59.2 percent) of the homes had radios (1934), and in 1935 48 percent of the homes in Millard County were so equipped. Only 1 home in 6 had a telephone (1934). A daily newspaper was taken in a little over one-half of the homes and a weekly paper in a little over a fourth. The more remote areas had the highest percentage owning a car.

Most of the delta area population were Utah born. One-fourth of the farmers and one-third of the homemakers were born in Millard County. One out of 10 lived within 10 miles of his birthplace, while two-thirds were within 250 miles of it.

Those who had always lived in the area had been economically more successful in both good times and bad than had those who had moved into it.

Pioneer social adaptation in the Palouse country of eastern Washington, 1870-90, F. R. YONER (*Wash. State Col. Res. Studies*, 6 (1938), No. 4, pp. 131-159).—This article is based on personal interviews with 50 pioneer men and women living in all parts of the Palouse country of eastern Washington, made in 1936, 1937, and 1938. The author found that pioneer families have adapted themselves basically to the conditions prevailing in the Palouse country.

A study of Virginia's rural marginal population, A. D. EDWARDS (*Va. Expt. Sta.*). (*Social Forces*, 17 (1939), No. 3, pp. 385-395).—The author states that a large proportion of the rural white and Negro population exists on a bare subsistence plane of living economically and culturally. Areas with a high rate of marginality have high indices of fertility. Data indicate that differential fertility among socioeconomic groups is rather marked in Virginia. Vertical social mobility is not proceeding rapidly. The low level of achievement of marginal people can be explained entirely from a cultural point of view. The author concludes that there is need for bold experimentation in practical means of bringing about an improvement in the condition of marginal folk.

Arizona's farm laborers, E. D. TETEAU (*Arizona Sta. Bul.* 163 (1939), pp. 293-336, figs. 4).—This study, made as of April 1936 and including 1,500 farm laborers' households located in the Upper Gila, Salt River, Yuma-Gila, and Casa Grande Valleys, deals with the composition and character of Arizona farm laborer population, its location, and its adequacy. More than one-half of the

heads of laborers' households were of Mexican origin born in the State of Sonora or in southern Arizona. Another third of them were from the Cotton Belt, from other States, or native to Arizona, and the remainder were Yaqui Indians, Negroes, or Orientals. The greater part of all farm laborers' households made no change in residence during a sample period of 15 mo. Similarly, a very large part of the heads of laborers' households made no change in occupation. More living children were reported by Mexican mothers of completed families than by mothers in other racial and nativity groups. Though smaller than Mexican families, the size of completed families among native white and other laborers was sufficient to provide replacements for older laborers and a surplus population for other than agricultural industries. Since almost 70 percent of the heads of households who were farm laborers were under 45 yr. of age as compared with 50 percent of the tenants and 36 percent of the farm owners and managers, it was evident that farm laborers as a class were in the most vigorous years as compared with other agricultural classes. Farm laborers' households were located in the open country in the proportion of two of every three households.

Arizona's resident farm labor supply was found to be numerically adequate for the hired labor requirements of Arizona's irrigated farms during the seasons from January through April and from May through August 1937. Many farm laborers were without steady employment during the January-April season. January requirements were sufficient to regularly employ about three-fourths of the resident laborers, leaving out of consideration the out-of-State laborers who came to pick cotton. By March the requirements had fallen to a low mark for the year, only three of every five resident laborers being regularly needed as hired laborers. During the middle of the May-August season, farm laborers were practically all needed to meet farm requirements, but later there was a falling off in demand so that more than one-fourth of them were not needed during August.

From September through December all resident laborers on farms and in rural towns were required and many more were drawn from other sources. Early in the season extra laborers were drawn from Indian reservations, larger towns and cities in Arizona, and from other States, and these numbered more than one-half as many as the total resident supply in rural towns and on farms in irrigated areas. Numbers of workers increased through October into November as the cotton picking season advanced, until a peak supply of 45,600 hired laborers was reached, 20,000 of whom had come from outside the State.

Rural youth in farm organization and other national agency programs (*Washington, D. C.: Amer. Youth Comm., 1939, pp. [4]+82*).—This report consists of two parts, older youth activity in leading farm organizations, by E. L. Kirkpatrick and A. M. Boynton, and older young people's part in civic and character-building organizations, by M. M. Chambers and E. L. Kirkpatrick. They are designed to inform the general reader of the multiplicity of organizations reaching into rural fields.

Rural youth speak, J. J. LISTER and E. L. KIRKPATRICK (*Washington, D. C.: Amer. Youth Comm., 1939, pp. [5]+96, pls. 2, figs. 7*).—This is a detailed analysis of the replies from rural young people interviewed in a comprehensive survey by the American Youth Commission.

The demographic basis of old age assistance in the South, T. L. SMITH. (*La. State Univ.*). (*Social Forces, 17 (1939), No. 3, pp. 356-361, figs. 4*).—The author indicates that while the proportion of aged persons in the population has assumed great social significance in the Nation as a whole, the proportion of the aged in the South is low and youth is superabundant.

Interests of rural people as portrayed in weekly newspapers, C. B. HOFFER (*Michigan Sta. Spec. Bul. 298 (1939), pp. 30, figs. 3*).—This study shows that interests pertaining to the personal affairs and relationships of residents in rural communities are the dominant ones, and this constitutes a basic principle in rural community development. The neighborhood and similar social groups are important in contemporary life, notwithstanding the great increase in the influence of the larger secondary groups. General news occupied only 12 percent of the total news content of the 35 Michigan weeklies studied, and news items about State affairs 8.2 percent. The rest consisted of local and county news. The distribution of percentages among the different subjects in local news indicated the readiness of response residents in rural communities will be likely to make to programs of community improvement. Following neighborhood and personal news, other topics appeared in the order agriculture, school, church, civic and patriotic affairs, announcements, political affairs, recreation, adult education, business, and health. "The ranking of these subjects on the basis of percentages derived in the study constitutes a norm to which reference may be made when plans in community development are contemplated."

The analysis of editorials shows that the rural weekly papers contributed to the development of interests pertaining to local community affairs by directing the attention of readers to matters which might otherwise be overlooked, or by interpreting events which related to the community. "The more abstract values were considered, and in this respect the local paper performed a role similar to that of the church, the school, or public forum in the development of interests relating to the community."

AGRICULTURAL AND HOME ECONOMICS EDUCATION

American farming: Agriculture I, A. BOSS, H. K. WILSON, and W. E. PETERSEN (*Saint Paul, Minn.: Webb Book Pub. Co., 1939, pp. XIV+526, figs. [251]*).—This is the first of four books for use in studying agriculture. It is designed especially to serve the needs of junior high school students in gaining knowledge of agriculture as a mode of life. The several chapters deal with American agriculture, agricultural production areas and the economic forces modifying them, types of farming, farming as a vocation, starting a farm business, needs of man and how they are fulfilled, soil, growth of plants, grain, meadow and pasture crops, legumes, root and tuber crops, sugar plants, fiber crops, gardening, fruit growing, forestry, enemies of plants, beautifying the home grounds, livestock farming, dairying, the production of different kinds of livestock, feeding livestock, and vocational guidance in agriculture.

Observations on American dairy husbandry, A. S. FOOR ([*Gt. Brit.*] *Col. Estate Mangt., Rpts. Col. Trav. Scholars Agr., No. 5 (1937), pp. VII+151, figs. 33*).—The sections of this report on a traveling scholarship in agriculture describe and discuss the normal milk production on typical farms, current methods of improvement of commercial dairy cattle, feeding, control of quality of milk, and dairy husbandry research in the United States and Canada.

Agricultural engineering in North America and Germany, C. CULPIN ([*Gt. Brit.*] *Col. Estate Mangt., Rpts. Col. Trav. Scholars Agr., No. 6 (1939), pp. XII+162, figs. 43*).—The sections of this report of a traveling scholarship in agriculture describe and discuss the scope and accomplishment of agricultural engineering in the United States and Germany, the organization of the research and educational services, and the recent developments in the two countries.

Forest conservation in the social studies, W. P. BEARD (*U. S. Dept. Agr., Forest Serv., 1938, pp. [4]+1+147, pls. 5*).—This is a series of seven units

proposed for the use of high school social-studies teachers and course-of-study committees.

Short-time camps: A manual for 4-H leaders, E. GARDNER (*U. S. Dept. Agr., Misc. Pub. 346* (1939), pp. IV+90, figs. 12).—This manual for 4-H club leaders includes sections on types of camps, standards for facilities and their use, business management, camp organization and conduct, the camp program, and program content. An appendix includes descriptions of camp ceremonies by I. T. Bode and others, examples of report blanks, topics for group discussion, list of program events used in 4-H camps, and a bibliography.

FOODS—HUMAN NUTRITION

Food and welfare, F. L. McDougall (*Geneva Studies*, 9 (1938), No. 5, pp. 56).—In this brochure the author has attempted to interpret in terms of "consumer economics" the activities of the League of Nations through its economic and financial organization concerning nutrition and the standards of living as noted in published reports and from unfinished inquiries. The bases of the problems of nutrition are outlined, with the general dietary recommendations of the Technical Commission on Nutrition. Trends in food consumption in various countries are discussed, with the conclusion that "the problem of nutrition can best be stated as a problem of underconsumption of food, for the most part qualitative underconsumption, that is, underconsumption of the protective foods, but also in certain sections of the populations quantitative underconsumption of food, which amounts to incipient starvation. Further, this underconsumption of food, which has such disastrous effects in impairing health and reducing efficiency, is mainly attributable to the inadequacy of the available income for purchasing a sufficiency of both energy and protective foods." This aspect of the nutrition problem, economics of food consumption, is next reviewed, with the suggestion that there are "three theoretical means of effecting an improvement in nutrition through facilitating consumption of protective foods, firstly, through raising the lower levels of income, secondly, through a reduction in prices of the basic energy foods, thereby leaving more income available for the purchase of protective foods, and thirdly, through a reduction in prices of the protective foods. A lowering of prices of protective foods alone will not, however, greatly benefit people who have very little money to spare for buying such foods. It is clear that what is required is a general raising of the standard of living, for improved nutrition is only one aspect of an improved level of life embracing food, housing, clothing, education, and cultural activities."

Standards of living are then discussed, with the statement that "unemployment benefits, grants for large families, provision of free meals to school children, supplies of milk to pregnant and nursing women and to children are all excellent and necessary measures for the immediate relief of poverty," but that "it is not through such measures that the fundamental problems of underconsumption will be solved. There must be general constructive policies of economic betterment which shall aim at stimulating enterprise in all directions." The most promising means toward progressive betterment of living standards is thought to be through the governments intensifying their efforts toward increasing efficiency and thus reducing costs in both production and distribution. This line of advance in agriculture is considered in a chapter dealing with the agricultural problems, which, together with a final chapter on some results of policies of increased consumption, emphasizes the importance of national and international nutrition policies for the purpose of relating increased production to nutritional needs.

It is emphasized in conclusion that "the improvement in standards of living by policies designed to supply the consumer with cheaper energy foods and larger supplies of protective foods might have two outstanding results in the general economic field, namely, (1) a beneficial stimulus to world trade through the opening up of farm markets for manufactured goods, and (2) an alleviation of the effects of trade depressions."

Health needs of the Nation, T. PARRAN (*Pub. Health Rpts. [U. S.]*, 54 (1939), No. 22, pp. 919-924).—In this address, delivered at the 1939 Red Cross Convention, the author discusses the evidence of "malnutrition prevalent in a land of plenty," and states his belief that in the field of better nutrition "a broadly conceived, dynamically executed policy under the aegis of the American Red Cross might transform our whole national status." The job is considered to be three-fold. "It means re-education of millions in the use of foods. It means the machinery for getting food into empty hands, and finally, it means a vast multiplication and improvement of all present effort to grow gardens where there are none, to make sure that every child has the needed quart of clean milk a day, and to use every possible device that will encourage the individual to enrich his own diet by the means ready at his hand."

Report on nutrition (*Paddington, Eng.: Brit. Assoc. Labour Leg.*, pp. 118, figs. 3).—This report has been prepared by a committee of the British Association for Labor Legislation to acquaint the layman with the newer knowledge of nutrition, nutrition problems as they exist in Great Britain, and some of the measures being taken to cope with existing malnutrition and undernutrition, and to suggest certain changes in policies to meet consumption needs. Of particular interest are the chapters dealing with the feeding of school children in England and Wales; the relation of British agriculture to national nutrition and systems of farming and national health; and the status of milk consumption in rural areas, the consumer demand for milk, and the quality of the supply.

Nutrition and physical training, C. F. WHITE (*Jour. Roy. Inst. Pub. Health and Hyg.*, 2 (1939), No. 6, pp. 374-380).—In this presidential address to the nutrition and physical training section of the 1939 Congress of the Royal Institute of Public Health and Hygiene, Great Britain, the main steps in a national nutrition policy are enumerated as follows:

"(1) The ascertainment of the minimum food requirements for adequate nutrition at all ages and under all conditions of life as regards work and climate and taking into consideration social and religious customs and the relative availability of various types of food. (2) The ascertainment of the nature and extent of nutritional deficiencies. (3) The education of the public as to what constitute the essentials of an adequate diet and as to how such essentials should be purchased and prepared for consumption, and thus the creation of a demand for such essential foods. (4) The taking of the necessary steps to insure that such a demand can be met at prices which are within the means of the consumer and which at the same time afford a reasonable margin of profit to the producer."

Each of these steps is considered in some detail from the administrative point of view. "The problem of malnutrition is world-wide and its economic solution can only be found in an international nutrition policy."

Malnutrition: A challenge and an opportunity, F. G. BOUDREAU and H. D. KRUSE (*Amer. Jour. Pub. Health*, 29 (1939), No. 5, pp. 427-433).—In this paper, read at a joint session of the child hygiene and food and nutrition sections of the American Public Health Association at its 1938 annual meeting, the authors point out the lag between the advances in the science of nutrition during the last 25 yr. and their application by health and school authorities in detecting

malnutrition and promoting good nutrition. "Social agencies other than the health and school authorities have recognized the importance of a more precise knowledge of the problem and have attempted to apply to it the newer methods developed in the laboratories of biochemistry and physiology. The result is that we do not look to health agencies for advice and help on nutrition problems but to home economists and dietitians, the agricultural schools and land-grant colleges and universities."

Methods now in use or available for appraising nutritional status are discussed, existing evidence of malnutrition in the United States is reviewed, and a brief description is given of the plans for a comprehensive study on a co-operative basis by the departments of preventive medicine and pediatrics of Cornell University, the U. S. Public Health Service, the New York City Department of Health, and the Milbank Memorial Fund. This study includes medical and dietary histories of a large group of children, with extensive physical, physiological, biochemical, and clinical tests, the purpose being to select from the many tests and methods followed certain ones to be recommended for routine use in appraising nutritional status.

The food consumption of one hundred four families in Paco District, Manila, M. GUTIERREZ and F. O. SANTOS (*Philippine Jour. Sci.*, 66 (1938), No. 4, pp. 397-416).—This report is based on records, including weight as purchased and cost, of the food materials consumed in the three principal meals of each family for 1 day and other pertinent data relating to the families, which were from the working class of one district in Manila. The number in the families ranged from 2 to 12, with an average of 6. More than 50 percent owned their houses but few the land on which they were built. Only 6 percent of the families were illiterate. The analyses of the foods were based on composition data previously reported (E. S. R., 67, p. 337) or made for the present study. The calculated values for calories, proteins, fats, carbohydrates, and minerals were reduced to adult male units by means of the Lusk coefficients.

The average daily intakes per adult male unit were $2,107 \pm 40.87$ calories, 63 ± 1.35 gm. proteins, 33 ± 1.48 fats, 377 ± 7.01 carbohydrates, and 11 ± 0.4 gm. minerals. Carbohydrates furnished 88 percent of the calories and proteins 12 percent, with 45 percent of the total from animal sources, chiefly fish. The most variable factor in the diet was fat and the least carbohydrate. It is estimated that the vitamin B₁ intake probably allowed little margin of safety.

A comparison of these data with the results of similar studies of rural families in the Philippines showed that the urban diets furnished less energy, carbohydrates, and minerals but significantly more fats and a better quality of protein. The food cost per adult male unit decreased with increase in the size of the household. With increased income the proportion spent for carbohydrates decreased and that for meat, fish, and eggs increased. Very little was spent for milk and dairy products. Approximately 80 percent of the families spent about 50 percent of their income for food. This was reflected in the superiority of the diets of the families with the higher incomes.

Adequate low-cost family dietaries, E. C. G. WILSON (*New Zeal. Jour. Sci. and Technol.*, 20 (1938), No. 3B, pp. 144B-160B. fig. 1).—A series of weekly low-cost dietaries, based on the recommendations of the Technical Commission on Nutrition of the League of Nations (E. S. R., 75, p. 133), but adapted particularly to New Zealand food habits, is presented and discussed from the standpoint of certain changes in foodstuffs necessitated by local conditions, methods of computing prices, actual tests of the dietaries, certain disadvantages in them, and suggestions for further reduction of cost. The paper is of

particular value in showing that a considerable degree of flexibility in food selection to meet traditional food habits and local conditions is possible while still adhering in general to the recommended allowances of certain types of food.

Foods and nutrition [at the Hawaii Station] (*Hawaii Sta. Rpt. 1938, pp. 85-91, fig. 1*).—Included in this progress report (El. S. R., 79, p. 560) are summaries of studies by C. D. Miller on the response of young rats to graded doses of crystalline vitamin D₂ and on the content of various vitamins in whole fresh opihī, the Hawaiian limpet; by M. Potgieter on the utilization of calcium in taro by human subjects and by rats; by Potgieter, [T.] Takase, and L. Louis on the food consumption and family incomes and expenditures of 12 Japanese families near Honolulu; and by C. J. Hamre on the influence of splenectomy on the recovery from nutritional anemia in rats and on postnatal changes in the blood and blood-forming organs in rats from the breeding colony on adequate diet, as determined by analyses at various intervals from birth to 100 days of age.

Comparative digestibility of some soft curd milks in vitro, F. J. DOAN and C. C. FLORA (*Pennsylvania Sta. Bul. 380 (1939), pp. 30, figs. 13*).—The primary object of this investigation was to determine the accuracy of curd tension measurements as an index of the relative digestibility of various types of soft-curd milk. The method followed consisted of simultaneous determinations of the digestibility in vitro of samples of the milk by a method based on the one developed by Doan and Welch (El. S. R., 73, p. 231) and Lear and Skaggs (unpublished) and in vivo by feeding experiments on rats (weighing 100-200 gm.), with post-mortem examinations of the digestive tract of animals killed at various intervals following the feeding of a definite quantity of the milk. Curd tension determinations were also made with an American Curd-O-Meter. The data are presented in tables and in curves showing the progress of peptic and tryptic digestion in vitro.

The in vitro data were found to agree reasonably well with the in vivo data, but did not correlate with the curd tension values which proved for the most part unreliable, particularly for homogenized milk and to a lesser extent for trypsin treated milk, acidified milk, and base exchange treated milk. The digestibility of natural milk or pasteurized milk appeared to be roughly in inverse proportion to the curd tension, but no milk of this type was found to be as digestible, according to both in vivo and in vitro tests, as acidified milk, buttermilk, evaporated milk, and most samples of boiled milk. Evaporated milk and acidified milk showed more rapid digestion than any of the other types. The in vitro tests indicated very high initial digestion in the peptic period. This type of digestion is indicated by the very small curd particle size. Some samples of boiled milk, particularly boiled low curd tension milk, gave digestibility curves resembling somewhat those of evaporated and acidified milks, although not quite as satisfactory. All heated milks were acted upon by trypsin more rapidly than unheated milk.

It is concluded that curd particle size would be a more accurate index than curd tension of the digestibility of milk and its suitability for infant feeding.

Hydrogenated lard as a culinary fat, R. JORDAN (*Indiana Sta. Rpt. 1938, pp. 69, 70*).—This progress report (El. S. R., 79, p. 704) summarizes the results obtained in a comparison of the desirability of five different fats for use in frying doughnuts of the cake type as determined by smoking of the fat and absorption of the fat by the doughnuts.

Cooking studies with frozen poultry. (Iowa State Col.). (*U. S. Egg and Poultry Mag., 45 (1939), No. 3, pp. 156-159*).—This and the following paper

report a continuation by K. Hoffman of poultry cookery research under the direction of B. M. Lowe (B. S. R., 75, p. 718). The objectives of the present study were comparisons of the quality of the poultry, both uncooked and roasted, which had been chilled overnight before freezing with properly matched birds frozen within 2 hr. after killing and of birds drawn before freezing with those frozen before drawing. The carcasses frozen before drawing were stored for periods of 10, 30, and 90 days, after which they were defrosted, drawn, and refrozen. The drawn birds were also stored for the same periods of time. A total of 56 birds of two breeds, Buff Orpingtons and White Rocks, held under the same conditions before killing, was used in the 8 treatments involved in the comparison. The tests included for the raw samples odor, fatness, condition of the skin and flesh, and color and for the roasted samples scoring by a modified score card based on that developed by the Cooking Committee of the Cooperative Meat Investigations.

The odor of the uncooked birds became somewhat undesirable on prolonged storage before drawing. After cooking the differences in odor between the drawn and not-drawn birds were still significant for the Buff Orpingtons but not significant for the White Rocks. It is suggested that part of the undesirable odors may have volatilized during cooking. The cooking times per pound were practically the same for all groups, and the cooking losses were not affected by the time in storage before drawing or by the chilling treatment. Chilling before freezing gave no more palatable product except for tenderness than freezing within 2 hr. after killing. Juiciness was not affected by storage before drawing or by the chilling treatment, but storage in general resulted in some degree of deterioration of all of the birds regardless of treatment. Tenderness of the muscles, as judged by the score card, was not affected by length of storage after freezing nor by chilling overnight before freezing for the Buff Orpingtons. For the White Rocks the birds chilled overnight before freezing were more tender than those frozen 2 hr. after killing. Shear test readings also indicated increased tenderness as a result of chilling before freezing.

More palatability studies with poultry. (Iowa State Col.). (*U. S. Egg and Poultry Mag.*, 45 (1939), No. 4, pp. 212-214).—This paper reports a comparison of the effects on the quality of poultry of washing the internal cavity with a stream of water after drawing with simply wiping the cavity with a cloth. The carcasses were tested unfrozen and frozen.

In the unfrozen carcasses the differences were insignificant for the two treatments in the condition of the flesh, cooking losses, aroma and flavor on cooking, juiciness, tenderness, and pH (uncooked meat), but the carcasses which were washed scored significantly higher than those which had been wiped in the appearance of the skin. In the comparison of unfrozen with frozen carcasses, the unfrozen tended to be more flabby than the frozen, particularly with long storage, showed considerably smaller losses on cooking, and were more juicy, but had less desirable odor and flavor, particularly as the time of storage increased. The pH values of the uncooked meat of the unfrozen carcasses were significantly lower than those of the frozen carcasses immediately before cooking, but the values of the cooked birds were not significantly different.

[Comparative cost of home- and commercially produced white and whole wheat bread and rolls] (*Nebraska Sta. Rpt.* [1938], pp. 45, 46).—A summary is given of the results of this study in terms of the relative number of women baking bread at home or buying it, the types of fuel used and their relative cost for bread making, the factors affecting the cost of the product, comparative costs of home- and commercially made bread and rolls, and

factors which must be taken into consideration in determining which practice to follow.

Preservation of fruits and vegetables by freezing in the Pacific Northwest. H. C. DIEHL, E. H. WIEGAND, and J. A. BERRY (*U. S. Dept. Agr., Bur. Chem. and Soils*, 1939, MC-53, pp. II-58).—This mimeographed circular has been prepared to meet the requests for information on the part of those who wish to use refrigerated locker plants for preserving home-grown foods for home use, and to some extent it represents a revision and expansion of information noted previously (*E. S. R.*, 77, p. 724). The purpose of freezing preservation, the factors determining satisfactory freezing of fruits and vegetables, and the microbiology of frozen fruits and vegetables are first discussed, after which general suggestions are given for the preparation for freezing of berries, other fruits, and vegetables, with specific suggestions for several representatives of each group. For each a list is given of the varieties or types common to the Northwest which are best adapted to freezing, desirable varietal characteristics are pointed out, directions are given for harvesting, handling, and preparing the material for freezing, and the most suitable types of containers and methods of packing are indicated.

Canned baked apples. [I], II, J. RUFFLEY, JR., J. A. CLAGUE, and O. R. FELLERS. (Mass. Expt. Sta.). (*Canning Age*, 20 (1939), Nos. 2, pp. 68-70, 82, fig. 1; 4, pp. 179-181).—This paper presents the results of a series of studies undertaken for the purpose of determining apple varieties most suitable for commercial canning as baked whole apples, the best methods for the preparation and baking of the apples, and the effect of the canning process on the vitamin C content. Much of the information presented is equally applicable to the home-canning process.

Glazing or cooking in a sugar sirup was found to give a more attractive and better tasting product than baking. A 40 percent sirup (40° Brix) was considered the best concentration. The substitution of 5 percent of the sugar by honey or 20 percent by dextrose is recommended as giving an attractive and well-flavored product. The time required for cooking varied from 5 to 15 min., depending upon the variety of apple, degree of maturity, size, and time held in storage. Of the varieties tested, those relatively high in pectin and acid content proved most satisfactory. These included Baldwin, York, Northern Spy, Rhode Island Greening, and Gravenstein, with preference for the first three because of their better color. Suggested additions for improvement in appearance and flavor are small amounts of certified color, spices, particularly pure oil of cinnamon, and acids such as 0.35 percent orthophosphoric, malic, or tartaric acid.

Tabulated data on canned apples of several varieties showed in each case a greater retention of vitamin C in the glazed than the baked, the losses averaging 65 percent in the baked and 44 percent in the glazed apples. The vitamin C content in the solid portion and sirup of canned glazed apples of different varieties was as follows: Northern Spy 60 and 60 International Units per 100 gm. for solid portion and sirup, respectively; Baldwin 40 and 60; Rhode Island Greening 20 and 20; Delicious 20 and 10; and York 10 and 20 units per 100 gm., respectively.

Growth and reproduction on a low fat diet. C. G. and J. B. MACKENZIE and E. V. MCCOLLUM (*Biochem. Jour.*, 33 (1939), No. 6, pp. 935-943, fig. 1).—The complete absence of lipids from the so-called "fat-free" diets heretofore used has been disproved by the lipid analysis of the two constituents of such diets (casein and yeast) which might possibly carry traces of lipids. Methods are described for preparing a defatted yeast extract, the fat content of which

did not exceed 0.01 percent and a casein in which the lipid content had been lowered from 1.45 to 0.02 percent. The basal diet as finally assembled contained a maximum lipid content of 0.0078 percent, of which 0.0022 percent was due to carotene and calciferol and 0.0056 percent to impurities in the casein and yeast. Of the two supplements which were given separately, methyl linoleate contained no lipid and a vitamin E concentrate given at a level of 5 mg. per rat twice weekly was estimated to contain at the most 70 percent of extraneous matter. This low fat diet has been found satisfactory for good growth and reproduction in rats. Feeding experiments on this diet, with and without vitamin E, have furnished no evidence for the existence of a hitherto unknown fat-soluble factor necessary for growth or reproduction in the rat. Early symptoms of paralysis in adult rats on the diet without vitamin E were completely prevented by a highly potent concentrate of vitamin E.

The specific dynamic effects of proteins when added in different amounts to a maintenance ration, M. KRISS. (Pa. Expt. Sta.). (*Jour. Nutr.*, 15 (1938), No. 6, pp. 565-581, fig. 1).—Adopting the principle set forth in an earlier paper (E. S. R., 74, p. 79) that more significant measurements of the specific dynamic effects of food nutrients can be made if the heat production of the experimental animal, when maintained in energy and nitrogen equilibrium, is used as the base value instead of the fasting metabolism, the author has determined the specific dynamic effects of dried heart muscle, casein, and gelatin with rats at levels of 1.5 and 3 gm. per day as supplements to a basal maintenance ration, with the heat production on the maintenance ration alone as the base value.

Casein showed the greatest and heart muscle the smallest specific dynamic effect when this was expressed as total calories or as percentage of metabolizable energy. At the 1.5-gm. level the values in terms of calories per 24 hr. were casein 2,904, gelatin 2,280, and heart muscle 1,944 and as percentage of metabolizable energy 46, 40.7, and 26.4 percent, respectively. Expressed in calories per 100 calories of protein catabolized, the specific dynamic effect of each of the proteins was about the same at both levels of feeding. The net energy values of the supplements were also practically identical at the two planes.

"The results indicate that the specific dynamic effects of proteins may be satisfactorily determined within a certain range above the maintenance plane of nutrition, with the heat production of energy and nitrogen equilibrium as the base value."

The mineral and nitrogen metabolism of college women (*Nebraska Sta. Rpt.* [1938], pp. 44, 45).—This progress report describes the scope of the study and summarizes the results to date with respect to storage of minerals and nitrogen.

The calcium requirements of adult man and the utilization of the calcium in milk and in calcium gluconate, F. R. STEGERDA and H. H. MITCHELL. (Univ. Ill.). (*Jour. Nutr.*, 17 (1939), No. 3, pp. 253-262).—This paper reports a long-time calcium balance experiment on a single adult male subject 35 yr. of age and normally weighing about 85 kg. The plan of the experiment was to subsist on a low calcium diet, with determinations of the daily loss of calcium in urine and feces, and then increase the calcium by stages by the addition of skim milk powder or calcium gluconate until calcium equilibrium was reached. Each period of definite calcium intake lasted from 12 to 32 days, although the collection periods were of only 4 days' duration.

On the basal diet furnishing an average of 195 mg. of calcium daily, the average daily balances obtained in three periods were -99, -121, and -109 mg.,

with an average of -110 mg. The average excretion amounted to 304 mg. daily, of which 68 percent was by way of the intestinal tract. Approximate equilibrium was secured when the diet was supplemented with 40 gm. of skim milk powder furnishing 542 mg. of calcium, the average balances over two 20-day periods being -7 and -4 mg. daily. Skim milk powder in amounts of 50 gm. daily was no more effective than 40 gm.

In periods in which the additional calcium was furnished as calcium gluconate, an amount furnishing 639 mg. of calcium daily gave an average balance of $+53$ mg. and in an amount furnishing 482 mg. a balance of -26 mg. By interpolation the amount of calcium from this source necessary for equilibrium was estimated to be about 534 mg. or practically the same as when furnished by milk.

The total calcium on which equilibrium was obtained, 735 mg. (including 540 mg. in the supplement and 195 mg. in the basal diet), amounted to about 92 mg. per kilogram of body weight as compared with an average of 9.75 mg. derived by Mitchell and Curzon from a review of all available data. As 540 mg. was required to change the average daily balance from -110 mg. to approximately 0 , it is concluded that the calcium in both milk and calcium gluconate is utilized only to the extent of about 20 percent.

A long-term experiment with rats on a human dietary.—II, Calcium and phosphorus depletion and replacement, W. E. GAUNT, J. T. IRVING, and W. THOMSON (*Jour. Hyg. [London]*, *39* (1939), No. 2, pp. 91-108, fig. 1).—An extension to the third generation of rats of the comparison of milk and green vegetables with calcium and phosphorus salts as supplements to a poor human dietary (E. S. R., *79*, p. 709) is reported, with results confirming those of the earlier study. The diet supplemented with the calcium and phosphorus salts proved as effective as that containing milk and green food furnishing equivalent amounts of calcium and phosphorus in promoting reproduction, bone calcification, and tooth formation, and in inducing growth in the first generation, but proved incapable of maintaining the same growth rate over several generations. It is concluded that calcium and phosphorus were the chief but not the only deficiencies in the human dietary tested.

The iron of human blood serum, B. S. WALKER (*Jour. Lab. and Clin. Med.*, *24* (1938), No. 3, pp. 308-315).—A simple method for the measurement of the total iron of blood serum, based on the Fowweather method, is described, and data obtained with it are reported for the serum iron of 12 normal medical students, 2 untreated and several treated cases of pernicious anemia, a number of cases of hypochromic and other types of anemia, and 2 cases of polycythemia.

The values obtained for the normal subjects ranged from 0.04 to 0.23 mg., with a mean value of 0.13 mg. or iron per 100 cc. of serum. The untreated cases of pernicious anemia gave values slightly above the normal, 0.27 and 0.3 mg. per 100 cc., respectively. Under liver therapy these values dropped gradually to within the normal range. In hypochromic anemia the values were low but seldom below 0.04 mg. per 100 cc. Treatment with iron was followed by a rise to normal in the serum iron. In aplastic and hemolytic anemias the values were high. In 1 of 2 cases of polycythemia the value obtained was below normal and in the other above normal.

Bone development in normal and rachitic rats, W. C. RUSSELL, M. W. TAYLOR, and M. T. DUNCAN. (N. J. Expt. Stas.). (*Jour. Nutr.*, *18* (1939), No. 1, pp. 27-33, figs. 3).—The bone development in stock colony rats from 3 to 54 days of age and in similarly reared rats receiving a rachitogenic ration from 24 to 54 days of age was studied by obtaining radii at 3-day intervals and photographing the split, stained sections. The average width of the epiphyseal

cartilage for rats on the stock colony ration decreased continuously and tended to become constant after about 36 days of age. The narrowing of the epiphyseal cartilage ceased within 3 days after the animals were placed on the deficient ration, and a widening began which continued for from 18 to 27 days, after which no further widening occurred. Growth rate was markedly retarded immediately after the rats were placed on the rachitogenic ration.

Heat loss from the human body, E. F. DU BOIS (*Bul. N. Y. Acad. Med.*, 2. ser., 15 (1939), No. 3, pp. 143-173, figs. 13).—In this lecture, delivered before the Harvey Society, December 15, 1938, the literature on the subject is reviewed, and the extensive investigations of the author and his associates on the relation between heat production and heat losses under various conditions (E. S. R., 80, p. 558) are discussed in considerable detail. In conclusion, various suggestions are given as to future applications of work of this type.

[Vitamin studies by the Idaho Station] (*Idaho Sta. Bul.* 229 (1939), pp. 32, 33).—Progress is reported on studies of the factors of the vitamin G complex in potatoes and the relative requirements of male and female rats for vitamin E as present in wheat germ oil.

The vitamin content of green string beans when cooked or canned and stored, H. L. MAYFIELD and J. E. RICHARDSON (*Montana Sta. Bul.* 373 (1939), pp. 14).—The Burpee Stringless Green Pod variety of string beans raised under irrigation in the experimental gardens of the station at an altitude of 4,800 ft. was used in this study of the effect of cooking by ordinary household methods and of canning in the pressure cooker, with suitable corrections for the elevation, on the content of vitamins A, B₁, and C in green string beans. The canned beans were tested after 6 mo. of storage both when freshly opened and after reheating. Additional vitamin C studies were made on some of the beans canned both in glass and in tin and opened at monthly intervals. Biological growth methods were used for vitamins A and B₁ in comparison with the U. S. P. reference cod-liver oil for vitamin A and the international standard clay for vitamin B₁. For vitamin C both curative methods with guinea pigs and chemical methods by indophenol titration were used.

In comparison with the raw beans, which were found to be a good source of vitamin A and vitamin B₁ and an excellent source of vitamin C, the freshly cooked beans were estimated to have lost none of their vitamin A or B₁ potency and from 30 to 40 percent of their vitamin C. The canning process itself caused no greater destruction of vitamin C than cooking, but within the 2 months' storage before the first tests of the effect of increased length of storage were made there was a notable decrease in the C content of the beans in both the glass- and tin-canned products. There seemed to be little further deterioration in the tin cans but a gradual decrease in the beans canned in glass.

An average serving of 70 gm. of the cooked or canned beans was estimated to supply the various vitamins in the following quantities: For freshly cooked beans vitamin A 840 International Units, vitamin B₁ 23 I. U., and vitamin C from 7 to 12 mg.; for the canned beans stored 6 mo. and reheated on opening, vitamin A 700 I. U., vitamin B₁ 14 I. U., and vitamin C 3 mg.

The distribution of vitamin B₁ (thiamin) in meat and meat products, O. MICKELSEN, H. A. WAISMAN, and C. A. ELVEHJEM. (*Wis. Expt. Sta.*). (*Jour. Nutr.*, 17 (1939), No. 3, pp. 269-280).—The vitamin B₁ content of various meats and meat products was determined in the raw state and for a limited number of products after cooking by various household methods. The rat growth method was used with the basal diet of Arnold and Elvehjem (E. S. R., 80, p. 562). Each series was composed of about 40 rats weighing between

35 and 45 gm. at the beginning of the experiment. All of the animals were kept on the basal ration for 1 week and then groups of two rats, a male and female, were given as supplements graded amounts of the tissues ground and dried in thin layers in a current of warm air at 45°–60° C. One group was kept as negative control on the basal ration alone and one received 80 µg. of crystalline vitamin B₁ per 100 gm. of ration. The assays were made over a 6-week period, with weekly weighings. The increases in body weights of the test groups were compared with the standard group and the vitamin B₁ value calculated by a simple proportion.

On the dry weight basis the highest values obtained were with pork muscle. Two samples of pork loin gave values of 13 and 20 International Units per gram, 2 of pork ham values of 11 and 20, and 1 of smoked ham of 11 I. U. per gram. The higher values were obtained from animals slaughtered later in the season and presumably older. Like differences were obtained with the flesh of pullets and of cockerels nearly 3 yr. old, although the concentration of the vitamin was much lower than in the pork. The dark meat of the pullets contained 1 and of the cockerels somewhat less than 1.8 I. U. and the light meat 2.5 and 3 I. U., respectively, per gram. Beef round contained 3 and leg of lamb 4 I. U. per gram. A composite sample of beef heart from 8 animals contained 10 and a sample of pork heart 8 I. U. per gram. Corresponding values for kidney were 5 and 8 and liver 4 and 5.3 I. U. per gram. The values for beef kidney, liver, and spleen were in good agreement with those reported by Arnold and Elvehjem, using the chick growth method (E. S. R., 81, p. 455).

The samples used for cooking were commercial cuts of meat which were tested before and after cooking according to the directions given by Child (E. S. R., 80, p. 846). The values obtained are reported in terms of the percentage of destruction of the vitamin by different methods of cooking as follows: Frying—beef round and pork ham no loss, veal hindquarter 45 percent, smoked ham 10, and pork loin 35 percent; roasting—beef round 61, veal hindquarter 59, and pork loin 50 percent; broiling—beef round 50 percent; baking—pork loin 50 percent; and stewing—beef heart 55 and beef kidney 40 percent.

The data are discussed with reference to the contribution of meat and meat products to vitamin B₁ requirements, using the Williams and Spies estimates of from 200 to 500 I. U. daily (E. S. R., 80, p. 710), with the conclusion that "even though meats are used in the diet to the extent of only 7 percent, they are capable of supplying one-third of the human vitamin B₁ needs. When meat such as pork is used, the proportion of the day's requirement thus supplied is correspondingly increased. A pork chop, even when fried, may supply the total daily requirement of this vitamin."

New procedure for the chemical determination of vitamin B₁ in natural media [trans. title], P. MEUNIER and C. BLANCPAIN (*Bul. Soc. Chim. Biol.*, 21 (1939), No. 5, pp. 649–664, figs. 5).—The electrocolorimetric method described is based upon the discovery that the same part of the thiamin molecule is attacked in the reaction with diazotized sulfanilic acid in an alkaline medium as proposed by Kinnersley and Peters* and in the production of the thiochrome by the oxidizing action of ferricyanide, also in alkaline medium as proposed by Jansen (E. S. R., 77, p. 298). The nonspecificity for thiamin in either test alone is overcome by conducting the Kinnersley and Peters test with and without potassium ferricyanide. Using the process of kinetic colorimetry, the authors have found that, as in the case of vitamin C, the reaction of vitamin B₁ is com-

* *Biochem. Jour.*, 28 (1934), No. 2, pp. 667–670.

pleted more rapidly than with other substances which also give the test. Consequently, the readings are taken at 30 sec. and at 1 min.

Various methods in use for determining thiamin are reviewed, the technic proposed is described in detail, and the application of the method to the determination of thiamin in various yeasts and of pure thiamin in the presence of certain interfering substances is discussed.

Does vitamin B complex or B₁ aid digestion and gastro-intestinal conditions? H. McDONELL. (Univ. Calif.). (*Fruit Prod. Jour. and Amer. Vinegar Indus.*, 18 (1939), No. 11, pp. 338, 339, fig. 1).—This is a brief review of the somewhat conflicting evidence on the question as to whether vitamin B₁ alone or the vitamin B complex is of greater aid in digestion and the prevention or correction of gastrointestinal disturbances.

The question of the regulation of the detoxifying processes by vitamin B₁ [trans. title], H. BROTEVOGEL and E. TONUTTI (*Klin. Wchnschr.*, 18 (1939), No. 13, p. 471).—On the principle that by increasing the liver glycogen the detoxifying properties of the liver cells are correspondingly increased, the authors have used injections of massive doses of vitamin B₁ with dextrose for the treatment of severe burns. In 17 cases in which the treatment has been applied the dosage has consisted of up to 10 mg. Benerva (a vitamin B concentrate) in 10 cc. of a 10 percent dextrose solution four times a day. Two of the subjects who had severe burns covering over two-thirds of the body surface and were not treated until the third day died on the sixth and seventh days, but even in these there was prompt relief of the smarting soon after the administration of the dose. In all of the other cases there was rapid recovery.

The influence of the diet and energy intake upon acute vitamin B₁ deficiency in the rat, G. A. SCHMADKE and C. O. PRICKETT. (Ala. Expt. Sta.). (*Jour. Nutr.*, 15 (1938), No. 6, pp. 607-620).—In this comparison of the effectiveness of various diets in producing neuromuscular symptoms of vitamin B₁ deficiency in the young rat, as described by Prickett (*E. S. R.*, 72, p. 884), the most effective diets studied were those in which carbohydrate (sucrose or cornstarch) and fat (coconut fat) each furnished approximately half of the nonprotein source of energy.

On these diets about 90 percent of the rats developed the neuromuscular symptoms. The time of onset was influenced both by the method of feeding and by the nature of the nonprotein constituents of the diet, but was longer on limited (isocaloric) feeding than on ad libitum feeding. Replacement of one-half of the energy from the carbohydrate by its equivalent in coconut fat had no effect in the ad libitum feeding but increased the time in the limited feeding procedure. Replacement of cornstarch by dextrinized starch or three-fourths of the sucrose by coconut fat increased the time in both methods. Both of these replacements more than doubled the energy intake before the onset of the symptoms. On the limited feeding loss in weight was less rapid and less marked and anorexia less acute than on the ad libitum feeding.

The authors conclude that if the proper diet is used the incidence of the neuromuscular symptoms of acute vitamin B₁ deficiency is so consistent in young rats that these symptoms serve equally well as the basic criterion of acute vitamin B₁ deficiency in the rat as in the pigeon and chick.

Adrenal atrophy and senescence produced by a vitamin deficiency, A. F. MORGAN and H. D. SIMMS. (Univ. Calif.). (*Science*, 89 (1939), No. 2320, pp. 565, 566).—An extension of the observations concerning the graying of the fur of rats on diets deficient in the filtrate factor or factors (*E. S. R.*, 79, p. 506) is noted in this preliminary communication. Young rats of mothers deprived of the factor from the date of birth of the young developed the graying as early as 8 weeks of age. Litters of mothers deprived of the factor from the day of

ming were of normal size and weight, but none could be reared to weaning age. In rats kept in the deficient state for several months, ulcers reminiscent of the leg ulcers of nutritional origin and reported from the Tropics developed. These were not cured by crystalline vitamin B₆, but were cured rapidly by concentrates of the filtrate factor. Graying was also cured by the filtrate factor concentrates and by injections of relatively large doses of adrenal cortex extract but not by additional vitamin B₁, B₆, riboflavin, copper or iron, nicotinic acid, or epinephrin. Histological studies of animals suffering from this deficiency revealed striking atrophy of the adrenals, loss of elastic layer of the skin, failure of spermatogenesis, and atrophy of hair follicles, with intermediate stages paralleling the graying and regenerative stages during recovery. The unknown factor is thought to affect particularly the function of the adrenal cortex. Whether or not the factor is the same as the antichick pellagra filtrate factor of Lepkovsky et al. (E. S. R., 76, p. 839) has not been determined.

The vitamin C content of sulfured and nonsulfured grape juice [trans. title], K. H. BÜSING and W. RAABE (*Klin. Wchnschr.*, 17 (1938), No. 50, pp. 1766-1768).—A commercial grape juice during the preparation of which enzymes and micro-organisms are destroyed by a method of electric heating which does not raise the temperature above 68° C. and all air is removed before sealing was found to have an ascorbic acid content, as measured chemically, of 14.5 mg. per liter in samples taken from freshly opened bottles. The value fell rapidly after the bottle had been opened even if resealed. Grape juice preserved with sulfites was without antiscorbutic effect when tested on guinea pigs. The authors are of the opinion that the treatment of foods with sulfurous acid is destructive of vitamin C and should not be permitted.

The content of vitamin C in gastric juice [trans. title], M. DEMOLE and A. ISSLER (*Compt. Rend. Soc. Biol. [Paris]*, 130 (1939), No. 12, pp. 1225, 1226).—Samples of pure gastric juice from 32 subjects were analyzed for ascorbic acid by indophenol titration, with verification of the absence of other reducing agents. Minimum, maximum, and average values obtained, grouped by the degree of acidity of the juice, are as follows: For 9 samples with less than 1 part HCl per 1,000, 0.15, 0.8, and 0.43 mg. per 100 cc.; for 13 samples with normal acidity (between 1 and 2 parts per 1,000), 0.25, 1.5, and 0.71 mg.; and for 10 with more than 2 parts of HCl per 1,000, 0.45, 0.98, and 0.68 mg. per 100 cc. It is noted that these figures correspond to the published values of Peters and Martin (E. S. R., 77, p. 887). Although the content of vitamin C was particularly low in the achylous subjects, the variations between normal and hyperacidic juices were inconsistent and slight.

Influence of vitamin C saturation on the gastric juices [trans. title], A. ISSLER and M. DEMOLE (*Compt. Rend. Soc. Biol. [Paris]*, 130 (1939), No. 12, pp. 1227, 1228).—Eight of the subjects noted above were given saturation tests with ascorbic acid to determine to what extent the vitamin C content of gastric juice is affected by saturation. Although the ascorbic acid content of the samples was in all cases higher than before saturation, the differences were very slight in comparison with changes in the urine and showed no relation to the degree of saturation. The acidity of the juice as HCl remained practically unchanged.

Blood studies of vitamin C during pregnancy, birth, and early infancy, [I, II], C. E. SNELLING and S. H. JACKSON (*Jour. Ped.*, 14 (1939), No. 4, pp. 447-451, fig. 1).—This report is presented in two parts. In the first part, by S. H. Jackson, the technic of the method followed, which is essentially the same as the macromethod described by Mindlin and Butler (E. S. R., 80, p. 728) using the Evelyn photoelectric colorimeter, is described in detail.

In the second part, by C. E. Snelling, data are reported on the application of the method to the determination of plasma ascorbic acid of women in successive stages of pregnancy, the relation of the plasma ascorbic acid of breast-fed infants to the content of the vitamin in their mothers' milk, and a comparison of the plasma ascorbic acid of artificially fed and breast-fed infants in the same age group. In the first series the average values of the plasma ascorbic acid of groups of from 6 to 13 women at each of the periods of pregnancy studied showed a progressive decrease from 0.6 mg. per 100 cc. up to 5 mo. to 0.42 mg. at full term and 0.23 mg. per 100 cc. immediately after delivery. The cord blood ascorbic acid varied from 0.1 to 1.47 mg., with an average of 0.77 mg. per 100 cc. as compared with values of 0, 0.92, and 0.23 mg. per 100 cc. for the maternal blood. Five infants with plasma ascorbic acid content of from 1 to 2 mg. per 100 cc. had received breast milk, which contained more than 4 mg. per 100 cc. Of 5 others with a plasma content of from 0.7 to 1 mg. per 100 cc., 4 had received breast milk containing over 4 mg. and 1 below 2.5 mg. per 100 cc., and 3 whose blood contained from 0 to 0.5 mg. were all receiving milk with less than 2.5 mg. of ascorbic acid per 100 cc. In 12 artificially fed infants ranging from 1 week to 3 mo. of age who were receiving no vitamin C additions, minimum, maximum, and average plasma ascorbic acid values were 0.05, 0.52, and 0.19 mg. per 100 cc. Corresponding values for 15 breast-fed infants all under 3 mo. of age were 0, 1.6, and 0.91 mg. per 100 cc.

"As a result of these studies, the following recommendations are made: Artificially fed babies should receive additional vitamin C from the time they are 2 weeks of age. The mothers of breast-fed babies should have adequate vitamin C in the diet, and, if there is any question of lack in the mother's diet, the baby should receive additional vitamin C."

The clinical assessment of nutrition, E. H. WILKINS (*Pub. Health [London]*, 52 (1939), No. 10, pp. 296-300).—In this paper, read at a meeting of school medical officers in Birmingham, England, the topics discussed include low weight: height ratios as evidence of malnutrition, posture as an index and cause of ill health, quality and texture of the skin apart from classical deficiency diseases affecting the skin, pallor and anemia, brightness of the eye and luster of the hair as indeterminate and misleading factors, and dental caries and bone deformities. It is emphasized that the assessment of the nutritional state of children of school age tends to lack precision, and should be checked as far as possible by information on the actual diets and incomes of the families from which the children come.

Treatment of rickets and tetany with a single massive dose of vitamin D; vitamin D shock therapy, H. VOLLMER (*Jour. Ped.*, 14 (1939), No. 4, pp. 491-501, fig. 1).—Three clinical reports with X-ray and laboratory data are given in support of the statement that rickets and tetany in children can be cured by peroral administration of a single dose of 600,000 International Units of vitamin D incorporated in milk. In these and other cases observed by the author and reported from other laboratories, there were no symptoms of toxicity and no contra-indication. Under this treatment the curative effect is said to be more prompt than that obtained with the daily administration of small doses, the serum calcium and phosphorus become normal, and roentgenographic evidence of calcification shows within a week. Hypernormal values of serum phosphorus may occur after the shock therapy, but they usually decline to a normal level in from 2 to 4 weeks. The method is thought to have particular value in neonatal and infantile tetany, severe rickets, rickets associated with pneumonia or pertussis, rickets associated with chronic infections, and in cases where the parents of a rachitic or tetanic child are indifferent or unreliable. The possibility of a

successful vitamin D shock prophylaxis over the entire winter period with a single dose of 400,000-600,000 I. U. is discussed. For this purpose the subcutaneous administration of the dose is recommended as possibly being superior because the injection would be given by the physician and there would thus be a guarantee of the administration of a precise quantity at a known time.

Vitamin E destruction by rancid fats, J. WEBER, M. H. IRWIN, and H. STEENBOCK. (Wis. Expt. Sta.). (*Amer. Jour. Physiol.*, 125 (1939), No. 3, pp. 593-600).—In this investigation of the effect of rancid fats of known peroxide value and of various aldehydes, ketones, and other decomposition products which may be present in rancid fats on the destruction of vitamin E, a diet similar to that of Olcott and Mattill (*E. S. R.*, 71, p. 731) was used to produce vitamin E deficiency in rats and a partially hydrogenated vegetable shortening as the standard material for restoring fertility in female rats. This fat, with proper treatment, was also used as a rancid fat to test the destruction of vitamin E.

The untreated fat, when incorporated in the basal diet at a 5-percent level, was capable of restoring fertility in female rats whose previous gestations had ended in resorption. This activity was destroyed by certain fats made rancid by aeration, by heat in the presence of oxygen, by treatment with ozone, or by the addition of palmitic peroxide, but was not destroyed by fats heated under nitrogen reflux nor by fats to which acrolein, allyl alcohol, or straight chain aldehydes and ketones had been added. No destruction of the vitamin occurred when the source of the vitamin and the rancid fat were fed separately. The destructive action of a fat made moderately rancid by aeration was not overcome by increasing the amount of vitamin E three times above the minimum necessary for fertility.

Studies on the vitamin K requirements of the rat, J. D. GREAVES (*Amer. Jour. Physiol.*, 125 (1939), No. 3, pp. 429-436).—Vitamin K deficiency symptoms (hemorrhagic tendencies associated with low blood prothrombin values) were produced in 12 out of 77 rats on a modification of the Almquist vitamin K-free basal diet for chicks (*E. S. R.*, 76, p. 581), and the symptoms were cured by vitamin K concentrates. In the majority of the animals, however, the deficiency could not be produced by dietary means alone but necessitated partial block in the drainage of bile into the intestinal tract. Bile fistula and jaundiced rats, as well as normal rats raised for extended periods of time on a vitamin K-free diet still excreted appreciable amounts of vitamin K. This is thought to suggest the synthesis of minimum amounts of the factor in the intestinal tract.

The nature of the factor which is concerned in loss of blood coagulability of bile fistula and jaundiced rats, J. D. GREAVES (*Amer. Jour. Physiol.*, 125 (1939), No. 3, pp. 423-428).—This paper confirms earlier work showing that the marked bleeding tendency of the bile fistula or jaundiced rats is associated with an increased bleeding time and low blood prothrombin values and can be cured by the administration of vitamin K concentrates in the presence of bile salts.

[Fortification of foods] (*Milbank Mem. Fund Quart.*, 17 (1939), No. 3, pp. 217, 221-262, figs. 2).—The papers listed below were presented at a symposium on the subject at the 1939 meeting of the Institute of Nutrition: Fortification of Foods With Vitamins and Minerals, by A. F. Morgan (pp. 221-229) (Univ. Calif.); Fortification in a General Program for Better Nutrition, by L. J. Roberts (pp. 230-240); The Public Health Aspects of the Fortification of Foods With Vitamins and Minerals, by W. H. Sebrell (pp. 241-247); Governmental Control Problems in the Fortification of Foods With Vitamins and Minerals, by E. M. Nelson (pp. 248-254) (U. S. D. A.); and Retention, Restoration, and Fortification of Vitamins in Foodstuffs, by A. E. Taylor (pp. 255-262).

The requirements of the dog and the rat for nicotinic acid, T. W. BIRCH (*Jour. Nutr.*, 17 (1939), No. 3, pp. 281-292, *figs.* 3).—This paper is presented in two parts, in the first of which evidence is reported leading to the conclusion that the minimum protective dose of nicotinic acid for dogs is about 1 mg. daily for an animal weighing from 5 to 10 kg. On a body weight basis, a rapid increase in weight and complete protection were secured on 0.25 mg. of nicotinic acid per kilogram, a slight increase in weight and complete protection on 0.13, and no protection on 0.084 and 0.027 mg. per kilogram of body weight.

In the second part the conflicting literature on the need of nicotinic acid by the rat is reviewed, and evidence is reported leading to the conclusion that nicotinic acid is not an essential substance for the rat.

Studies on experimental rickets in rats.—II, The healing process in the head of the tibia and other bones, G. S. DODDS and H. C. CAMERON. (W. Va. Expt. Sta.). (*Amer. Jour. Pathol.*, 14 (1938), No. 3, pp. 273-296, *pls.* 6, *fig.* 1).—In continuation of an earlier investigation of the outstanding structural changes in the bones of rats during the active phases of rickets, with special reference to the behavior of the epiphyseal cartilage in the head of the tibia,⁹ the authors have made a similar study of the healing process as brought about mainly by the administration of irradiated ergosterol to young rats in which well-developed rickets had been produced by the Steenbock-Black rachitogenic diet. Observations are reported on 26 normal controls, 31 in various stages of rickets, and 68 in various healing stages. For 35 of the animals three records were obtained: (1) X-ray photographs at weekly or more frequent intervals, (2) microscopic sections stained with hematoxylin-eosin, and (3) silver preparations similar to the line test but carried further. For all of the other animals the first two records were obtained. The X-ray films included all the bones of the legs of all of the animals, microscopic sections from the distal end of the femurs and of the radius and ulna, and particularly the head of the tibia. The 12 X-ray stages of Bourdillon et al. (*E. S. R.*, 68, p. 132) were used as a scale for measuring the progress of the healing but with a series of X-ray photographs from the authors' own material as a standard.

"The first indication of healing was calcification in the rachitic metaphysis close to the edge of the epiphyseal cartilage, whence it spread, first through the metaphysis toward the shaft and later into the cartilage toward the end of the bone. The preliminary reorganization of the metaphysis involved provisional dilute calcification of the osteoid, calcification of the exposed cartilage trabeculae, increase in amount of marrow, and its restoration to normal structure. The changes restored a somewhat normal configuration of trabeculae by exposing the rather parallel cartilage trabeculae. The end of the shaft undergoes much the same changes. At the same time the projecting cartilage masses became calcified and were partly removed, leaving calcified trabeculae very similar to those in the metaphysis. During the latter half of healing the shape of the bone became corrected, hematogenous marrow formed in the new end of the shaft which had been formed from the metaphyseal region, cupping was corrected, the entire epiphyseal cartilage became normal in thickness and structure, and the reorganized trabeculae attained normal dense calcification."

Mottled enamel in South Dakota, H. T. DEAN, E. ELVOVE, and R. F. POSTON (*Pub. Health Rpts. [U. S.]*, 54 (1939), No. 6, pp. 212-228, *figs.* 2).—This survey, conducted by the U. S. Public Health Service with the assistance of the South Dakota State Board of Health, covered a total of 53 cities, towns, and rural communities in 21 counties, with a total of 3,350 school children examined. In one

⁹ *Amer. Jour. Anat.*, 55 (1934), No. 1, pp. 135-160, *pls.* 3, *figs.* 2.

community where the water supply had been changed in 1928 from a deep artesian well to a dug shallow well, the survey showed in children of different ages the change in the mottled enamel condition of the teeth effected by the change in water supply. On the basis of this survey it is concluded that endemic mottled enamel in South Dakota is limited solely to users of artesian water obtained from the Dakota sandstone. This, however, includes an endemic condition in 41 communities divided among 20 counties, with a border line degree of endemicity in 5 counties and 30 other places listed as probably endemic areas.

Deficiency diseases in Kashmir, D. C. WILSON (*Lancet [London]*, 1939, *I*, No. 17, pp. 1019-1021, figs. 5).—In connection with a comparative dietary survey in various communities in India clinical examinations of the children were made, a brief report of which for Kashmir is presented. Records of height and weight of 406 children of from 5 to 15 yr. of age showed that the Kashmir girls tended to be shorter and lighter than English girls of the same age, but there was little or no difference in the boys who, however, were heavier than boys from south Indian towns. A remarkably low incidence of dental caries was shown. Various deficiency diseases occurred among the children and adults. Phrynoderma or toad skin was seen in 10 percent of the children, angular stomatitis in 3, and rickets in 2 percent. Late rickets, osteomalacia, beriberi, and pellagra were found among the adults. Night blindness and scurvy were noted occasionally at the outpatient departments of hospitals. Stone in the bladder was not commonly met.

Studies in nutritional anemia of the rat.—I, The influence of the spleen on recovery, C. J. HAMRE and C. D. MILLER (Hawaii Expt. Sta.). (*Folia Haematol. [Leipzig]*, 61 (1938), pp. 224-238).—In this extension of an earlier investigation in which marked changes were noted in the spleens of rats made anemic on a milk diet (*E. S. R.*, 74, p. 286), 16 anemic rats were splenectomized and fed curative agents, and recovery was compared with that of 15 anemic animals which had not been splenectomized but had been subjected to laparotomy only. After the operative treatment, all animals were fed 0.5 mg. of iron and 0.25 mg. of copper daily in addition to milk. Hemoglobin determinations, blood cell counts, and blood smears were made for all of the animals on the day of operation and at the beginning of the supplementary feeding. The blood studies were made daily for 21 days for 12 splenectomized and 13 control animals. For the others the blood samples were taken daily to the ninth day and then on the eleventh, fourteenth, and twenty-first days. All the animals were killed and autopsied at the end of the period of observation.

All of the animals recovered promptly, and the blood pictures were practically normal at the end of 14 days. The similar rate and degree of recovery of the splenectomized and nonsplenectomized animals is thought to furnish definite proof that the spleen is not necessary for recovery from nutritional anemia. A marked increase in the number of normoblasts and leucocytes in the circulating blood occurred on the second and on the fifth or sixth days of recovery for all animals, but the increase was much greater in the splenectomized than in the control animals. These observations are thought to suggest that splenectomy temporarily disturbs hematopoietic processes, and that a new equilibrium is established at about the seventh or eighth day.

Anemia caused by feeding cholesterol to guinea pigs, R. OKEY and V. D. GREAVES. (Univ. Calif.). (*Jour. Biol. Chem.*, 129 (1939) No. 1, pp. 111-123, fig. 1).—When 1 percent cholesterol was fed to guinea pigs in addition to an adequate synthetic diet, the livers became greatly enlarged and fatty and after about 5 weeks the animals became seriously anemic. The red cell counts in some instances fell 2 or 3 million within 2 or 3 weeks, nucleated red cells ap-

peared, and blood slides showed cells in the process of degeneration. Splenic enlargement took place simultaneously with the blood changes, the spleens increasing to about 10 times their normal size within from 7 to 9 weeks. The tissues of animals killed after from 7 to 9 weeks on the cholesterol diet showed an increased free cholesterol content of the liver, spleen, heart, lungs, and blood and lower lecithin values than normal. The livers on histological examination showed fatty infiltration and cellular destruction and the spleen engorgement with cellular debris and gross necrosis.

The results are thought to indicate that "while esterified cholesterol is to be regarded as physiologically comparatively innocuous, cholesterol in a free state must have a very definite effect on cell structure and on the capacity of the cell to take up nutrient substances from water solution."

TEXTILES AND CLOTHING

Adequacy of labeling of certain textile fabrics with regard to fiber content, H. FLETCHER and L. DENNHARDT. (Kans. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 58 (1939), No. 12, pp. 895-903, pls. 3).—The investigation reported was undertaken to determine to what extent authentic information is available to the purchaser of textile fabrics concerning fiber content. A total of 268 fabrics was purchased in 18 stores in 7 towns and cities of the Midwest. At the time of purchase information on the labels or material with reference to fiber content was noted and in all cases where there was no information the salesman was questioned. The methods followed in the identification and analysis of the fabric included microscopic identification and quantitative mechanical, chemical, and microscopical analyses of the mixed fiber fabrics.

Of the 133 fabrics made of one type of fiber, 57 were labeled and of these labels 23 proved to be accurate, 32 partially accurate, and 2 inaccurate. Information secured from the salesman on 79 fabrics proved accurate for 25, partly accurate for 48, and entirely inaccurate for 6. The inaccuracies were chiefly in the three types of rayon fabrics—acetate, cuprammonium, and viscose rayon. Of the 135 mixed fabrics, 117 were made of 2 and 18 of 3 kinds of fiber. Only 34 of these fabrics were labeled and the information was not completely accurate for any of them. Information secured from the salesman for 110 of the fabrics was accurate for 9, partly accurate for 94, and completely inaccurate for 7.

HOME MANAGEMENT AND EQUIPMENT

[Equipment studies by the Indiana Station], G. M. REDFIELD (*Indiana Sta. Rept. 1938*, pp. 68, 69, fig. 1).—This progress report includes summaries of an extension of the study of refrigeration for the farm household and farm produce (*El. S. R.*, 79, p. 718) and of a study of small electric mixers and beaters for household use.

Further studies of selected types of domestic gas stoves, A. E. BARAGAR (*Nebraska Sta. Res. Bul. 111* (1939), pp. 24, figs. 15).—The investigation previously noted (*El. S. R.*, 77, p. 140) has been extended to similar studies of six gas ranges, all with small round surface burners and all but one with the enclosed type of top with either removable or fixed burner bowls. Special attention has been paid to causes of the production of excessive carbon monoxide gas by the top burners, more data have been obtained on cooking top efficiencies, and automatic lighters have been studied further. The most extensive work reported, however, was on oven tests, including checks on thermostat calibra-

tion, temperature distribution, and heat losses. A special apparatus was devised for measuring vent losses and is described and illustrated.

The significant results obtained in the investigation as a whole have been expressed in the form of a list of optimum requirements of cooking tops and ovens for gas ranges to insure satisfactory performance for economical operation. This list constitutes a set of specifications of value to the prospective purchasers of a gas range whether it be for natural, manufactured, or bottled gas.

Performance analysis of selected types of kerosene stoves, M. M. MONROE (*Maine Sta. Bul. 394* (1939), pp. 433-521, figs. 24).—This report of an extensive investigation of the performance of kerosene stoves of different types has been prepared to be of service to other investigators on cook stoves, teachers of household equipment, extension service workers, manufacturers of kerosene stoves, and others particularly interested in the principles of heat transfer for cooking. The first section of the bulletin contains material of a general nature on the principles involved in surface burner and oven cooking with ranges of temperature required, and the various types of kerosene stoves and the principles on which their operation depends. The procedures and results of the present investigation are then discussed in considerable detail for surface and oven cooking, with tables and charts reporting the original data. This technical section is followed by an appraisal of the performance and construction of the stoves tested in which standards for appraising oven and surface burner performance are given in the form of questions and answers for the types of stoves tested. The summary is divided into three parts. The first includes the practical applications of the study which are of interest to the housewife, the second consists of suggestions to manufacturers for improvements in the construction of kerosene stoves, and the third lists for the benefit of other investigators certain precautions to be taken in controlling the testing conditions.

Buying and using kerosene stoves, M. M. MONROE and E. M. COBB (*Maine Agr. Col. Ext. Bul. 251* (1938), pp. 23, figs. 6).—This nontechnical bulletin has been prepared, chiefly from information obtained in the investigation noted above, to acquaint the housewife with some of the characteristics of kerosene stoves of the three general types of long-chimney wick burners, short-chimney wick burners, and short-chimney wickless burners. The question and answer method of presenting the information is used throughout the text, prefaced by brief statements as to the performance which can be obtained from some kerosene stoves and the details of construction which add to the durability of the stove.

Studies in family life [of the Nebraska Station] (Nebraska Sta. Rpt. [1938], pp. 46, 47).—This progress report summarizes the results of a comparison of the adequacy of personality judgments, as determined by the method previously described (E. S. R., 80, p. 571), of farm, small town, and city young people in the State.

MISCELLANEOUS

Abbreviations used in the Department of Agriculture for titles of publications, C. WHITLOCK (*U. S. Dept. Agr., Misc. Pub. 337* (1939), pp. 278).—This supersedes Department Bulletin 1330 (E. S. R., 53, p. 599).

Report of the Hawaii Agricultural Experiment Station, 1938, [L. A. HENKE ET AL.] (*Hawaii Sta. Rpt. 1938, pp. 101, figs. 11*).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

High lights in agricultural research in Idaho: Forty-sixth Annual Report [of Idaho Station] for the year ending December 31, 1938, C. W. HUNGERFORD (*Idaho Sta. Bul.* 229 (1939), pp. 47, fig. 1).—The experimental work not previously reported is for the most part noted elsewhere in this issue.

Fifty-first Annual Report of [Indiana Station], 1938, J. H. SKINNER, H. J. REED, ET AL. (*Indiana Sta. Rpt.* 1938, pp. 117, figs. 35).—The experimental work not previously referred to is mostly noted elsewhere in this issue.

Fifty-first Annual Report of the [Michigan Station], 1938, V. R. GARDNER (*Michigan Sta. Rpt.* 1938, pp. 125-136).—This consists mainly of lists of publications and projects.

Fifty-second Annual Report of [Nebraska Station, 1938], W. W. BURE (*Nebraska Sta. Rpt.* [1938], pp. 59).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

Annual summary of publications (*Utah Sta. Cir.* 112 (1939), pp. [4]).—Abstracts of Bulletins 282-288 and Circulars 110 and 111 are given, with lists of reprints.

Agriculture in the twentieth century (*Oxford: Univ. Press, 1939, pp. X + 440, pl. 1, figs. 3*).—This volume of essays was designed for presentation to Sir Daniel Hall, and was planned to cover the more important scientific, technical, and administrative developments during the years of his leadership in British agriculture. The essays are as follows: Agriculture and the Civil Service, by H. E. Dale (pp. 1-20); Agriculture and the State—the Financial and Economic Results of Control, by J. A. Venn (pp. 21-49); Agricultural Conditions and Policies, 1910-38, by A. W. Ashby (pp. 51-86); Agricultural Education in College and County, by J. A. Hanley (pp. 87-121); The Art of Husbandry, by J. A. Scott Watson (pp. 123-135); The Farmer's Business, by C. S. Orwin (pp. 137-162); Soil Science in England, 1894-1938, by E. J. Russell (pp. 163-191); Grassland, by R. G. Stapledon (pp. 193-221); Developments in Plant Breeding, by H. Hunter (pp. 223-260); Outlines of the History of Plant Virus Research, by R. N. Salaman (pp. 261-289); Plant Protection, by J. C. F. Fryer (pp. 291-307); Landmarks in the Development of Scientific Fruit-Growing, by R. G. Hatton (pp. 309-360); Some Problems of Animal Nutrition, by C. Crowther (pp. 361-395); The Evolution of Milk-Production, by J. Mackintosh (pp. 397-421); and Agriculture and National Health, by J. B. Orr (pp. 423-433).

NOTES

Arkansas University and Station.—Dr. J. W. Reid, assistant professor and assistant in rural economics and sociology, has resigned as of August 31. Recent appointments include Dr. D. F. Eveleth, assistant professor of veterinary research in the Iowa College, as head of the department of bacteriology and veterinary science, beginning September 6; Dr. Warren Gifford as head of the department of animal industry, effective August 21; Mildred Stenswick as instructor in home economics, beginning September 11; and W. H. Wiley as instructor in animal industry, effective September 1.

Colorado College and Station.—Dr. Charles H. Kick, head of the department of animal husbandry during the past academic year and dean of agriculture and director of the station since July 1, died August 27. Dr. I. E. Newsom, vice president of the college and dean of the division of veterinary medicine, has been appointed acting director of the station, and Alvin Kezer, agronomist, acting dean.

Dr. Kick was born in Philadelphia on September 5, 1900, graduating from the Pennsylvania College in 1922 and receiving the M. S. degree from the University of Illinois in 1924 and the Ph. D. degree from the University of Wisconsin in 1932. He had been associated with the animal husbandry work of the Illinois University from 1923 to 1927 and the Ohio Station from 1927 to 1938. During the last 2 years of this period he was located at Reynoldsburg in cooperation with the College of Veterinary Medicine of Ohio State University. His work had been mainly in animal nutrition, especially with poultry and the digestion of cattle.

Iowa College and Station.—Charles E. Rogers, head of the department of journalism in the Kansas College, has been appointed head of the department of technical journalism and editor of the publications of the station and the extension service. The appointment becomes effective in January 1940.

Kentucky University and Station.—Dr. Leonard J. Goss, assistant animal pathologist, has resigned. Recent appointments include R. H. Allen as associate professor and assistant in land economics; Dr. Bennett S. White, Jr., as assistant professor of agricultural economics and assistant in markets and cooperation; Robin M. Williams as instructor and assistant in rural sociology; W. O. Templeton, Jr., as instructor in farm crops; Wendell Binkley as assistant in markets; Dr. Paul F. Macy as assistant chemist; and Dr. Clifford Westerfield as assistant veterinarian.

North Dakota Station.—Dean H. L. Walster of the division of agriculture has been reappointed director of the station, Dr. H. C. Hanson becoming vice director.

Association of Land-Grant Colleges and Universities.—In order to permit of recommendations to the executive committee prior to the opening of the convention on November 15, as is now required by the executive body, special sessions will be held of the various sections on November 14. These sessions will begin at 10 a. m. and will continue through as much of the day as may be deemed necessary.

President J. A. Burruss of the Virginia Polytechnic Institute and president of the association was recently appointed as its representative on the advisory committee of 28 set up by the Secretary of Agriculture to assist in the formulation of policies to deal with the situation brought about by the European war as related to American agricultural economy.

EXPERIMENT STATION RECORD

VOL. 81

DECEMBER 1939

No. 6

THE DEPARTMENT OF AGRICULTURE APPROPRIATION ACT, 1940

In the year 1891 the *Record*, then in its second volume, began an analysis of the annual acts making appropriations for the support of the Federal Department of Agriculture. This analysis has been continued without interruption because of the general interest in the development of the Department and the belief that these acts serve as a convenient index of that development. As a matter of fact, the acts for successive years have seldom been fully comparable without more or less interpretation, and the passage of supplementary legislation has often been a further complication. Nevertheless, on the whole a picture is obtainable which is reasonably accurate and enlightening.

The latest of these acts was signed by President Franklin D. Roosevelt on June 30, 1939, and became effective on the following day. It was extensively modified by reorganization changes and supplementary legislation, the net result of which was to provide a total in appropriations and reappropriations of \$1,385,758,620. In the aggregate, this is practically the same as the \$1,383,621,893 appropriated for the previous year. In addition, provision was made of \$119,599,918 for the restoration of capital of the Commodity Credit Corporation as of March 31, 1939, and the direct appropriations for the Farm Credit Administration were increased from \$3,782,880 to \$18,741,000.

Both the Commodity Credit Corporation and the Farm Credit Administration had been independent of the Department, but both became associated with it on July 1, 1939, following the passage of the Reorganization Act of 1939 and the promulgation of plans thereunder by the President. Also added to the Department's activities were the Rural Electrification Administration, with a 1940 appropriation of \$42,790,000, and the Federal Farm Mortgage Corporation, for which the use of \$9,500,000 of the funds of the Corporation was authorized for administrative expenses. On the other hand, the Bureau of Public Roads, for which \$191,000,000 was appropriated in the 1940 act, became the Public Roads Administration of the newly established Federal Works Agency. The Bureau of Biological Survey, for which \$4,053,691 was appropriated in the 1940 act, was transferred to the

Department of the Interior. The foreign offices of the Foreign Agricultural Service were transferred to the State Department, and the unit retained in the Department of Agriculture was re-named the Office of Foreign Agricultural Relations.

In addition to the interdepartmental changes brought about by Presidential order, several internal readjustments which had been effected during the year were reflected in the act. Prominent among these was the realignment of the economic work of the Department. In the new set-up the Bureau of Agricultural Economics is retained, with an appropriation of \$928,000, primarily as an agency for economic research (with an increase of \$37,000), but also to serve as the central agency of the Department, in cooperation with operating bureaus, the land-grant institutions, and county planning committees, to formulate coordinated action programs relative to agricultural production, distribution, and land utilization and conservation. There is also constituted, however, as a new administrative unit, the Agricultural Marketing Service, with an appropriation of \$6,096,333. The work of this Service includes studies in marketing farm and food products, the market inspection of these products, the market news service, the crop and livestock estimates, and the enforcement of the various regulatory acts relating to marketing. Most of its projects receive small increases in funds over the previous year, and the allotment for the crop and livestock estimates is raised from \$642,799 to \$747,510.

Another organization change was the transfer to the Bureau of Plant Industry of the Soil Survey and other basic research in soils and the merging of the Bureau of Agricultural Engineering with the Bureau of Chemistry and Soils to constitute the Bureau of Agricultural Chemistry and Engineering. The initial appropriation for this Bureau is \$1,379,369. This is a net decrease of \$41,600, the largest item in which is a \$38,300 curtailment in the fertilizer investigations.

By far the largest allotment appearing in the 1940 agricultural appropriation act is that for the conservation and use of agricultural land resources. The act itself appropriates \$429,560,000 and reappropriates \$70,000,000 additional for this purpose. It also provides \$225,000,000 for parity payments to producers of wheat, cotton, corn, rice, and tobacco; \$113,000,000 for the disposal of surplus commodities (in addition to \$92,678,812 provided for this purpose by a permanent appropriation); and \$47,975,000 (including reappropriations) for payments and administration under the Sugar Act of 1937. The total appropriations and reappropriations under the Farm Tenant Act are increased from \$40,923,000 to \$49,985,730. The Farm Security Administration receives \$160,700,000 in appropriations and reappropriations provided by the Emergency Relief Appropriation Act of 1939, a decrease from \$198,000,000.

The Special Research Fund of the Department under the Bankhead-Jones Act (E. S. R., 73. p. 269) is maintained at the \$1,400,000 level. For the four regional research laboratories (E. S. R., 80, p. 2-9) authorized by the Agricultural Adjustment Act of 1938 not to exceed \$3,200,000 was provided, and specific authority to conduct research on food products of farm commodities at these laboratories was included in the appropriation act.

Under the Office of Experiment Stations a total of \$7,093,485 is granted, of which \$6,848,750 represents payments to the States, Hawaii, Alaska, and Puerto Rico for agricultural experiment stations. This is an increase in payments of \$307,500 over the previous year, of which \$300,000 is under the Bankhead-Jones appropriations, which rise to \$2,400,000. For the administrative expenses of the Office, a total of \$189,735 (including an allotment of \$28,000 from the Special Research Fund) will again be available. The sum of \$83,000 is provided for the maintenance of the Federal Experiment Station in Puerto Rico, including an increase of \$17,755 for investigations of the economic production of rotenone-bearing insecticidal plants, quinine plants, and similar commodities.

The funds administered by the Extension Service are increased from \$18,809,387 to \$19,398,447. The amount available for payments to States and Territories in the fiscal year 1940 is \$18,470,583 (including the permanent Smith-Lever Act appropriation of \$4,701,165), which provides a net increase over 1939 of \$533,000. The full authorized increase of \$1,000,000 in Bankhead-Jones funds is provided, as well as \$203,000 for readjustments of allotments to individual States under an act approved April 24, 1939, but other grants of \$670,000 have been eliminated.

The airways weather service and research are promoted by an increase in the appropriations to the Weather Bureau for this purpose from \$2,500,000 to \$3,500,000. A further increase of \$185,000 in the Bureau's allotment for general weather service and research brings its total to \$6,172,870, including \$250,000 to provide the first unit of a building in Washington, D. C.

An apparent increase from \$13,746,752 to \$16,663,712 in the funds available for the Bureau of Animal Industry is attributable largely to the allotment of \$8,300,000 instead of \$5,403,000 for eradicating tuberculosis and Bang's disease. Increases of \$13,500, \$15,000, and \$20,400 in the funds for animal husbandry work, investigations of animal diseases, and the meat inspection are offset in part by a decrease of \$28,940 for cattle tick eradication.

The total for the Bureau of Plant Industry shows an increase from \$5,110,337 to \$5,183,009, distributed among six items, of which the largest are \$52,000 for sweetpotato and other fruit and vegetable crops and disease investigations and \$25,000 for one-variety cotton work.

These are offset in part by a reduction from \$168,457 to \$121,622 for soil fertility investigations. The Soil Survey again receives \$298,708.

The Forest Service is granted a total of \$20,294,466, and in addition \$10,000,000 is provided for the construction of forest roads and trails and \$300,000 for cooperative farm forestry, the latter being the initial appropriation under the act of May 18, 1937. There is also a deficiency grant of \$5,500,000 for New England hurricane damage repair, which is available until June 30, 1940. A new project is the authorization of a Tropical Forest Experiment Station in Puerto Rico, for which \$30,000 is granted. There are increases from \$11,569,754 to \$12,004,000 in the funds for the protection and management of the national forests; from \$628,361 to \$664,181 to permit of further research in the use of wood in building, including low cost housing; from \$121,295 to \$149,295 for forest economic studies; and from \$2,000,000 to \$2,200,000 for forest fire cooperation. A decrease is noted from \$648,403 to \$613,403 in the funds for forest management studies.

The funds provided in last year's appropriation act for the Bureau of Entomology and Plant Quarantine totaled for that year \$5,721,867, but these were further supplemented by two deficiency grants aggregating \$4,750,000 for insect pest and plant disease control, which sums were made available until December 31, 1939. The Bureau's appropriation in the new act totals \$6,199,809. Most of the allotments are continued unchanged, but among others increases are granted of \$460,000 for pink bollworm control and \$21,511 for Dutch elm disease eradication, while there is a decrease of \$25,000 for barberry eradication.

The remaining work of the Department is provided for much as at present. The Soil Conservation Service receives \$23,720,584, an increase of \$75,000 for research and demonstration work in the Everglades region of Florida. The Food and Drug Administration is increased from \$2,241,138 to \$2,741,138, the principal item being an enlargement of \$525,000 in the funds for the enforcement of the Food and Drugs Act. The Bureau of Dairy Industry receives an increase of \$4,000, and the Library one of \$3,800, making their totals \$721,405 and \$107,970, respectively. The Bureau of Home Economics receives \$325,085, which is an increase of \$20,000 for additional textiles and clothing investigations. The Commodity Exchange Administration is again granted \$623,380; the Office of Information \$1,965,910, which includes \$1,586,870 for the departmental printing and binding; the Secretary's Office \$896,447; the Office of the Solicitor \$231,280; and the Beltsville Research Center \$85,000.

RECENT WORK IN AGRICULTURAL SCIENCE

AGRICULTURAL AND BIOLOGICAL CHEMISTRY

Selenium in rocks, soils, and plants, A. L. MOXON, O. E. OLSON, and W. V. SEABRIGHT (*South Dakota Sta. Tech. Bul. 2* (1939), pp. 94, figs. 27).—Analyses of several samples of rocks from many of the geological formations indicate that selenium is usually present in the rocks of South Dakota but in most of them only in very small quantities. There are, however, some formations or beds within formations which contain a relatively large amount of the element, and where these formations or beds are exposed selenium poisoning in livestock may occur. The most consistently highly seleniferous formation in South Dakota is the Niobrara, the outcrop of which covers only a very small area within the State. The lower Sharon Springs member of the Pierre formation is also consistently highly seleniferous, but it is resistant to weathering and, therefore, seldom forms soils, and vegetation is seldom found growing on it. The upper Sharon Springs contains enough selenium to be considered dangerous from the standpoint of selenium poisoning. Although the relatively fresh outcrops of the member seldom support much vegetation, soils weather from it, and these soils support the growth of considerable vegetation. For the most part the Virgin Creek member of the Pierre formation is not highly seleniferous, but near the Missouri River in the southern half of the State the uppermost part of the member contains considerable selenium, and highly seleniferous soils have weathered from it. The Interior member of the Pierre formation is highly seleniferous in the area along the Missouri River in the southern half of the State, and in this area it forms seleniferous soils, but its selenium content decreases rapidly toward the northwest.

"Converter" plants were found to play an important part in the production of toxic concentrations of selenium compounds in crop and forage plants, in that the converter plant absorbs selenium compounds not available to other species and, on decaying to form part of the soil humus, leaves the selenium in a form readily taken up by other plants. Experiments with corn showed that selenates were taken up more freely than selenites or selenides. The selenium content of an extract of *Astragalus racemosus* was also readily taken up by corn plants.

Chemical investigations of the rhubarb plant, H. B. VICKERY, G. W. PUGHER, A. J. WAKEMAN, and C. S. LEAVENWORTH (*Connecticut [New Haven] Sta. Bul. 424* (1939), pp. 157, figs. 38).—The first two of the three parts into which this bulletin is divided deal with separate experiments carried out with leaves collected in 2 successive years from the same farm. The two lots differed somewhat widely in initial composition, and their behavior during culture in water in darkness was correspondingly different. In the experiments of the second year, the conditions of culture were extended to include culture in darkness in glucose solution and culture in light in water, the set of samples cultured in darkness in water serving as a control. The description of these experiments is given in considerable detail.

An interpretation of the data in terms of modern views of plant metabolism is presented, together with still further experimental results, in part 3

The research here recorded is a part of a general study of the chemistry of the plant cell, work on which has already been noted (E. S. R., 73, pp. 293, 748).

[Contributions of interest to factory technologists and chemists] (*Inter-rail. Soc. Sugar Cane Technol. Cong. [Baton Rouge, La.] Proc., 6 (1938), pp. 852-1113, figs. 72*).—These papers include Report of Special Committee on Uniformity in Reporting Factory Data, by F. W. Zerban (pp. 852-857); Review of Technical Progress Made in the Philippine Islands During the Past Three to Five Years, by C. W. Waddell (pp. 857-866); Conductimetric Determination of Ash in Sugar House Products, by F. H. C. Kelly and I. G. Newman (pp. 866-874); Graphic Critique of Factory Operations, by E. W. Kopke (pp. 874-880); The Value of Cane Juice as a Yeast Nutrient Medium, by K. Yamafuji and K. Ohtsu (pp. 880-885); A New Method for Determining Reducing Sugar, by K. Yamafuji and T. Yoshida (pp. 886-889); Precision Requirements in Refractometer Design, by J. W. Forrest (pp. 890-895); The Factory Comparison of Different Grades of Lime for Clarification Purposes, by R. R. Follett-Smith (pp. 896-899); A Contribution to Raw Sugar Clarification, by J. G. Davies (pp. 900-910); Automatic pH Control of Secondary Liming in the Fractional Liming and Double Heating Clarification System, by M. Moore (pp. 910-917); Work With Vacuum Pans, by A. L. Webre (pp. 919, 920); Improvements in the Manufacture of Sugar in Mauritius During the Last Four Years, by V. Olivier (pp. 922-924); Utilization of Bagasse, by R. C. Pitcairn (pp. 925-927); The By-Products of the Mauritius Sugar Industry, by R. Avice (pp. 928, 929); Refining Cane Sugar for the American Market, by R. Fortier (pp. 930-934); Studies of Louisiana Raw Sugar, by A. G. Keller (pp. 935-945) (La. State Univ.); New Possibilities of the Two-Boiling System, by A. L. Webre (pp. 945-951); Forced Draft for Bagasse Furnaces, by A. E. Seelig (pp. 952-963); Sucrose Loss in Filter Cake When Bagacillo Is Added as Filter Aid to Settlings, by W. A. Powe (pp. 963-967); Use of Hot Mingers at Central Jaramu, by R. E. Diago (pp. 968-970); Behavior of the Molasses of the Sucreries d'Egypte, by P. Neville (pp. 971-980); The Keeping Quality of Cane Sugar Molasses, by H. C. P. Geerlings (pp. 980-985); Effect on Factory Cane Juices and Sirups of *Leuconostoc mesenteroides* Isolated From Frost Damaged Louisiana Sugarcane of the 1937 Crop, by M. A. McCalip and H. H. Hall (pp. 986-1004); and The Influence of Sirup Composition on Sugar Quality, by C. A. Fort (pp. 1005-1018) (both U. S. D. A.); New Equipment for Improving the Efficiency of Mills, by E. L. Dennis (pp. 1019-1023); Reduction in Costs by Correct Filtration Procedure and Proper Selection of Filter-aid, by R. W. Schmidt and M. A. Harrison (pp. 1024-1032); The Use of Phosphoric Acid in Cane Sugar Manufacture and Refining, by G. P. Meade (pp. 1032-1038); Recent Improvements in the Suco-Blanc Process of Refining, by A. P. Fowler (pp. 1039-1043); Present Practice in Raw Sugar Manufacture in Queensland, by E. R. Behne and G. H. Jenkins (pp. 1046-1066); The Relation Between the Composition of Sugar Solutions and Produced Sugar, by P. Honig (pp. 1066-1068); Re-Use of Washed Sugar Liquor Filter Cake in Syrup Filtration and the Use of Vacuum Filters for Recovery of Values From Spent Filter-Aid, by W. J. Nelson (pp. 1069-1071); Electric Drive for Cane Mills, by C. A. Kelsey (pp. 1071-1074); Recent Investigations and Developments in the Processing of Masseccutes, by G. E. Stevens (pp. 1074-1093); Viscosity-Supersaturation Relationships of Industrial Sugar Solutions, by L. I. A. Micheli and O. S. de Gyulay (pp. 1094-1107); and Treatment of Low Grade Masseccutes, by C. W. Waddell (pp. 1108-1113).

Colorimetric method for the determination of sulfate in cane juice, P. E. CHU and F. E. HANCE (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.]*, 43 (1939), No. 2, pp. 137-143, pl. 1, fig. 1).—The proposed colorimetric method utilizes the color formed by sodium rhodizonate and the excess barium chloride which is used to precipitate the sulfate in the sample. The sodium rhodizonate forms a red solution with the excess barium. If there is no excess barium chloride, the solution is yellow. Full manipulative detail, including preparation of permanent color standards (sodium dichromate solutions), is given.

A technic for the determination of vitamin A in milk [trans. title], A. CHEVALLIER and S. MANUEL (*Compt. Rend. Soc. Biol. [Paris]*, 130 (1939), No. 6, pp. 553-555).—In the method described 12 cc. of 60-percent potassium hydroxide is added to 25 cc. of well-homogenized milk. After standing in an oven at 55° [C.] for 3 days, the mixture is extracted with 40 cc. of peroxide-free ether, decanted, washed 3 or 4 times with 5 cc. of water, and evaporated on a water bath. Ten cc. of the concentrate is then used for the spectrophotometric examination, which shows marked inflection in the region of 3,300-3,200 a. u. Irradiation of the solution causes this inflection to disappear in a short time, and a new curve is obtained, the difference between which and the first measures the quantity of vitamin A initially present in the milk. The test should be made on whole milk, for in separated milk some of the vitamin still remains in the skim milk.

Retaining flavor in canned foods, G. J. HUCKER and C. S. PEDERSON (*Farm Res. [New York State Sta.]*, 5 (1939), No. 3, pp. 8, 9).—The authors briefly note an investigation of canning temperatures and cooking periods in which some types of food products, though not all, were adequately sterilized at temperatures "much lower" than those now employed and in shorter cooking periods. The acid fruits were especially adaptable to this less severe processing. Successful preservation of tomato juice in tins filled at 180° F., sealed, and subjected to no further cooking, is mentioned.

Calcium added to canned tomatoes results in firmer product, Z. I. KERTESZ (*Farm Res. [New York State Sta.]*, 5 (1939), No. 3, p. 12, fig. 1).—Calcium chloride in the proportion of 0.022 oz. of anhydrous CaCl₂ per No. 2 tin was found enough to keep canned tomatoes sufficiently firm to come out whole from the tin and to retain their shape. This proportion of calcium chloride had no other effect upon the flavor than that of slightly increasing the salty taste, so that less salt had to be used. It was found also that the firmness of canned mature apples was improved by using calcium chloride as well as salt in the soaking tank. It is noted that this work grew out of a "theoretical research" upon factors affecting the behavior of pectins and the enzymes acting upon them.

SOILS—FERTILIZERS

The soils of Florida, J. R. HENDERSON (*Florida Sta. Bul.* 334 (1939), pp. 67, figs. 5, maps 2).—The first 17 text pages of this bulletin are given to a general discussion of the characteristics, development, and classification of soils. The remainder of the bulletin takes up factors in the development of Florida soils, their characteristics, distribution, and utilization, and presents some notes on their management and conservation, together with a key for their identification.

[Soil investigations of the New Mexico Station] (*New Mexico Sta. Rpt.* 1938, pp. 55, 56).—Work on effects of irrigation and cropping on soil profiles is briefly noted.

[Soil Survey Reports, 1932 Series] (*U. S. Dept. Agr., Bur. Chem. and Soils [Soil Survey Rpts.]*, Ser. 1932, No. 34, pp. 102, figs. 2, maps 2).—A survey

was made in cooperation with the [N. Y.] Cornell Experiment Station as follows: No. 34, Orleans County, N. Y., R. Wildermuth et al.

[Soil investigations at the Rhode Island Station] (*Rhode Island Sta. Rpt.* [1938], pp. 31-36, 44, 45).—These have included studies on optimum soil nitrate levels, effect of day length and acidity on the assimilation of nitrate and ammonium nitrogen, effect of crops on soil acidity, the relative availability for plants of different compounds of magnesium, growth retardation by chloropicrin in culture solutions, and effect of chloropicrin treatment on nitrification and ammonification in soil.

Erosion and related land use conditions (*U. S. Dept. Agr., [Soil Conserv. Serv.], [White Rock Reservoir Watershed], 1939, pp. 29, pls. 7, fig. 1. maps 2; [Muskingum River Watershed], 1939, pp. 36, pls. 12, fig. 2, maps 4).*—Conservation surveys (similar to those heretofore more fully noted) are reported as follows: On the Watershed of White Rock Reservoir Near Dallas, Texas, by R. M. Marshall and C. B. Brown; and On the Muskingum River Watershed, by H. H. Morse.

A chemical study of some soils derived from limestone, L. T. ALEXANDER, H. G. BYERS, and G. EDGINGTON (*U. S. Dept. Agr., Tech. Bul. 678 (1939). pp. 27).*—Chemical and physical studies of 10 profiles of soils derived from parent material residual from the decomposition of limestone (Frederick, Maury, Dewey, Decatur, Fullerton, Greenville, Lebanon, and 3 Hagerstown profiles) indicated that the gross chemical composition of the soil colloid does not always reflect the zonal and intrazonal group differences between the soils from which they came. Local variations in the soils were apparently caused by variation in the parent rock and relief. Differences between soils derived from similar parent rocks in widely separated localities seemed largely due to climatic differences. The silica : base ratio of the colloid fraction was found to correlate well with productivity except where physical factors were dominant.

Variation in available nutrients in an uncropped surface soil, R. J. BOBLEN (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.], 43 (1939), No. 2, pp. 133-136, fig. 1).*—An area of about 25 ft. square was maintained in a bare fallow condition for 2 yr., during which time two separate soil sample composites were taken twice each month for rapid analysis, the results being tabulated as pounds of available plant nutrients per acre. The variations from one set of samples to another were sufficient to lead to the conclusion that estimates of the fertilizer requirements of the soil based on soil analysis alone cannot be depended upon for accurate results.

Evaluating annual changes in soil productivity, A. W. KLEMM and O. T. COLEMAN (*Missouri Sta. Bul. 405 (1939), pp. 32, figs. 14).*—Analyses of soil from virgin and cultivated areas where no erosion has occurred indicated that cropping alone caused a decline of about 35 percent of the organic matter and nitrogen. United States census data for 60 yr. show a slight decline in Missouri yields of corn, oats, and hay, while wheat yields have remained about the same. The station experiments show that such improved crop practices as use of commercial fertilizers, bringing in of new land, better cultural methods, and improved varieties should have increased crop yields from 20 to 30 percent. These practices, therefore, have been compensating for the declining soil productivity.

From the yields of the principal crops on the outlying experimental fields where the total nitrogen content of the soil has been ascertained, the annual withdrawal of nitrogen supply of the soil was estimated for the different crops. From the yields of legumes on the outlying experimental fields the nitrogen turn-over provided by them on the soil on which they were grown was estimated. The total organic matter and nitrogen content of a silt loam soil being taken as a

guide to soil productivity and crop yields, it was found that a yield of about 10 bu. of corn per acre can be expected for each 1,000 lb. of total nitrogen in the surface 7 in. of an acre.

"The percent gain or loss of the total nitrogen supply of the surface 7 in. of the soil from different crops, cropping system, and soil treatments was considered as the productivity index. The percent of the total nitrogen and organic matter lost by sheet erosion when in different crops and cropping systems was taken as the erosion factor. Through the combined use of the productivity and erosion factors it is possible to determine approximately the annual gain or loss in productivity for a field, farm, or county. These productivity indexes and erosion factors provide an approximate measurement of the annual gain or loss in the productivity of the soil under the land use or soil farm management program of the farm."

Effect of organic matter decomposition on the solubility and fixation of phosphorus in alkaline soils, H. F. RHOADES (*Nebraska Sta. Res. Bul. 113* (1939), pp. 23).—The author studied the effects of the decomposition of organic matter and of the nitrification of ammonium sulfate and of urea on the solubility and fixation of phosphorus by two calcareous and two noncalcareous alkaline soils.

Crop residues and manure had no appreciable effect on the pH of the soils. Both urea and ammonium sulfate caused a lowering of the pH. The nitrification of urea and ammonium sulfate had no appreciable effect on the phosphorus removed from the calcareous soils but caused decided increases for the noncalcareous alkaline soils. Urea accelerated the fixation of applied phosphate. Crop residues increased the soluble phosphorus in all the soils studied. Horse manure increased the soluble phosphorus much more than any of the other materials. In general, the increases were greater for those materials with a higher phosphorus content. The decomposition of sugar beet tops retarded the fixation of applied phosphate. The calcium content of the soil solution was greatly increased by the urea and ammonium sulfate treatments, moderately increased by alfalfa tops, sugar beet tops, and potato tops, and slightly increased by the other organic materials. The phosphorus contents of the soil solutions were not appreciably affected by the addition of urea and ammonium sulfate. The phosphorus content in the soil solution was increased by the addition of organic material.

"The results of these studies indicate that the increases in soluble phosphorus due to applications of crop residues and manure to alkaline soils are largely due to the phosphorus released from the organic materials and not to a solubility of the native soil phosphorus."

[Soil fertility experiments], A. T. WIANCKO ET AL. (*Indiana Sta. Circ. 242* (1939), pp. 5-8; 243, pp. 1-6; 244, pp. 1-5; 245, pp. 1-3; 246, pp. 1-3; 247, pp. 1-4; 248, pp. 1-5, 6, 7).—All of these circulars report on a long-time general fertility experiment, and most of them deal with the topics how to treat this kind of land, best time for applying manure, and comparison of various phosphates, nitrogen materials, and liming materials over various periods up to 1938.

[Soil and fertilizer notes] (*Miss. Farm Res. [Mississippi Sta.], 1* (1938), Nos. 2, p. 3; 3, pp. 4, 7, fig. 1; 2 (1939), Nos. 1, pp. 1, 4, 8; 2, pp. 1, 3; 6, pp. 2, 7, fig. 1; 7, pp. 2, 6, 7, fig. 7).—The following brief articles are included: Vol. 1, No. 2, Good Husbandry for Productive Soils, by E. B. Ferris; No. 3, Poorer Soils Profit From Legumes When Good Crop Can Be Grown, by I. E. Miles, and Complete Fertilizer Needed for East Area of Yazoo-Mississippi Delta, by R. Kuykendall; Vol. 2, No. 1, 1939 Fertilizer Recommendations for Major Farm Crops of Mississippi, and State Soils Are Acid or Becoming Acid, both by C. Dorman;

No. 2, Fertilizer Materials, Formulas, and Methods of Usage Are Clarified, by C. Dorman, and Money Saved by Higher Analysis Fertilization, by R. Cowart; No. 5, Deer Licks [Saline Soil Spots], by C. Dorman; No. 6, Agricultural Areas of Mississippi, by I. E. Miles; No. 7, Lime and Basic Slag Increase Yields of Soybeans, Vetch, Austrian Peas, Lespedeza, Aid in Improvement of Soil, by W. B. Andrews, and Fertilizer in the Yazoo-Mississippi Delta, by R. Kuykendall.

Influence of potash fertilization upon the production and composition of dry matter, R. J. BORDEN (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.]*, 43 (1939), No. 2, pp. 119-123).—Small gains from potassium fertilizers in the production of dry matter from eight soils, which are not markedly deficient in available potassium, were significant only when the crop was harvested at optimum development, neither immature nor overmature. Although potassium fertilizers increased both the percentage and the total quantity of this mineral found in the dry matter at harvest, there was no correlation between potassium composition and final dry weights. The percentage of potassium in the total dry matter of the leaves and stems decreased as the age of harvest was delayed, but in the roots there was apparently a return of potassium when the plants passed maturity. The total amount of the potassium recovered in the total dry matter harvested decreased with the age at harvest. Such effects of potassium fertilizers are likely to introduce a complication into any attempt to interpret potassium composition figures.

Timely fertilizer facts for North Carolina farmers, C. B. WILLIAMS (*North Carolina Sta. Agron. Inform. Cir. 118* (1939), pp. [1]+4).—This circular is concerned with the desirability of including such organic nitrogen sources as cottonseed or soybean meal as well as nitrates or ammonium salts in fertilizer mixtures, and of purchasing fertilizers on the basis of quality and specific use.

AGRICULTURAL BOTANY

Edible wild plants, O. P. MEDSGER (*New York: Macmillan Co., 1939, pp. XV+323, [pls. 16, figs. 80]*).—The basis of this book is said to rest on data relative to edible plants collected over many years from books, published reports, papers, experiences of people, and wherever information on the subject could be obtained, including first-hand observation and experiment wherever possible. The manual does not include all the edible plants in the United States, but it is hoped that it will prove useful as a basis for future studies. Included in the work are edible fruits, nuts, seeds and seed pods, salad plants and potherbs, roots and tubers, beverage and flavoring plants, sugars and gums, and mushrooms. A general and four regional indexes are provided. There is an introduction by E. T. Seton.

Application of fine grain processing and condenser illumination enlarging to photomicrography, F. P. McWHORTER (*Oreg. Expt. Sta. and U. S. D. A.*). (*Stain Technol.*, 14 (1939), No. 3, pp. 87-96, figs. 4).—Photomicrographs requiring great resolution are ordinarily made by means of long initial projection, involving the use of heavy, often cumbersome apparatus designed to eliminate vibration. The author evaluated the possibility of using an intermediate projection distance equal to or greater than 160 mm., which is considered the minimum for efficiency, and recording the initial negative image in very fine grain. Then, by critical enlarging, a positive image is obtained which closely approaches the resolution obtainable by the finest long projection equipment. The initial projection permits eliminating the vibration difficulties attending long exposures so that critical printing at magnifications above 2,000 \times will consistently give good results, provided fine grain technic is mastered by the operator.

A low cost chamber for phytohormone tests, G. S. AVEBY, JR., H. B. CREIGHTON, and C. W. HOCK (*Amer. Jour. Bot.*, 26 (1939), No. 6, pp. 360-365, figs. 5).—The chamber described and illustrated in detail is said to permit perfect humidity control if kept in a temperature-controlled darkroom, thus obviating expensive humidity control equipment and maintenance expense. The chamber is large enough to accommodate 8-9 racks of oat seedlings (12 plants each) in water culture, and several control chambers may be housed in one darkroom. Schedules are given for the "deseeded" and "standard" *Avena* methods as used in comparative tests in this control chamber and in the usual constant-temperature constant-humidity test room, results of such tests on over 100 doz. plants being included.

Dioxan dehydration for paraffin embedded fucus slides, A. O. SIMONS (Colo. State Col.). (*Stain Technol.*, 14 (1939), No. 3, pp. 101, 102, fig. 1).—It is claimed that the usual difficulties can be overcome and excellent paraffin preparations made by the slow dioxan method and staining with fast green F. C. F. and safranin, procedure for which is given in detail.

Improvements in the permanent root tip squash technic, B. B. HILLARY (*Stain Technol.*, 14 (1939), No. 3, pp. 97-99).—Supplementary notes on the technic previously described (E. S. R., 80, p. 315), dealing with corn sirup and dioxan as mounting media.

A permanent transferable culture-tube label, D. J. BLAISDELL. (U. S. D. A.). (*Phytopathology*, 29 (1939), No. 8, pp. 761, 762, fig. 1).—As illustrated this tin-backed label is a split cylinder 1.25 in. long by 2 in. in circumference. A metal edge with 45° beveled corners is folded outward over the face of the cardboard. The label slips easily over the edges of tubes of various sizes, gripping them tightly.

The present members of the Commission on Standardization of Biological Stains (*Stain Technol.*, 14 (1939), No. 3, pp. 84-86).—A general statement on the commission, with list of present active members.

Progress in the standardization of stains, H. J. CONN (*Stain Technol.*, 14 (1939), No. 3, pp. 81-83).—A summary of progress and financial statement of the Stain Commission.

The use of Bismarck brown Y in some new stain schedules, G. W. BLAYDES. (Ohio State Univ.). (*Stain Technol.*, 14 (1939), No. 3, pp. 105-110).—Schedules are presented for stems and roots, middle lamellae in wood, white potato tuber and wheat grain sections, and *Tradescantia zebrina* epidermis.

The biology of bacteria; An introduction to general microbiology, A. T. HENRICI (*Boston and London: D. C. Heath & Co.*, [1939], 2. ed., pp. XIII+494, [pl. 1], figs. 112).—A revision of the work previously noted (E. S. R., 73, p. 844) to which two new chapters have been added, and the nomenclature and classification of bacteria have been changed to conform with the fifth edition of Bergey's Manual (E. S. R., 81, p. 489).

The apparent oxidation-reduction potentials of bright platinum electrodes in synthetic media cultures of bacteria, W. E. WARD (*Jour. Bact.*, 36 (1938), No. 4, pp. 337-355, figs. 6).—This study indicates that a number of hitherto neglected factors (controlling O₂ accessibility to the medium, zone effects from poisoning the electrodes by bacteria or gas bubbles, and type of electrode used in poorly poised media in presence of air) are important in measuring the apparent redox potentials in bacterial cultures, and that the accuracy of the results is greater with broth than with synthetic medium cultures—*Escherichia coli* being the test organism.

Resistance of non-spore-forming bacteria to heat, P. R. BEAMER and F. W. TANNER. (Univ. Ill.). (*Zentbl. Bakt. [etc.]*, 2. Abt., 100 (1939), No. 4-8, pp.

81-98, figs. 6).—The absolute thermal death times were determined for *Staphylococcus aureus* and five species of the typhoid-paratyphoid group in broth at pH 7.05. The time required was greatly reduced on heat exposures in broth at pH 8.05. Heating at 60° C. for 8.9 min in acid fruit juices was sufficient to kill all but the first of these bacteria, which required 18.8 min. The order of death in these nonsporiferous bacteria appeared to be logarithmic. A bibliography of two pages is included.

Heat sterilized reducing sugars and their effects on the thermal resistance of bacteria, J. C. BAUMGARTNER (*Jour. Bact.*, 36 (1938), No. 4, pp. 369-382).—Autoclaving reducing sugar solutions at 112° C. for 15 min. or steaming for 30 min. on 3 successive days resulted in forming a material directly toxic to *Escherichia coli* at 54° and capable of delaying its growth at 37°, but this toxic material was not formed when buffered or broth solutions of these sugars were sterilized by filtration. Filter-sterilized glucose, galactose, lactose, maltose, sucrose, mannitol, and glycerol at 0.5 M concentration in buffer or broth all protected *E. coli* against thermal destruction.

Heat resistance studies on selected yeasts, P. R. BEAMER and F. W. TANNER (Univ. Ill.). (*Zentbl. Bakt. [etc.]*, 2 Abt., 100 (1939), No. 9-13, pp. 202-211, figs. 5).—Thermal death times were determined for *Debaryomyces globosus*, *Monilia candida*, *Saccharomyces ellipsoideus*, *Torula monosa*, and *Willia anomala*. Except for *M. candida*, the time required to kill these organisms was slightly reduced when suspended in acid broth at pH 3.8. In general, the curves obtained in grape juice at pH 2.6 were similar. The order of death in the five yeasts studied was apparently logarithmic. A bibliography is included.

The mycorrhizal habit in crop plants, with a reference to cotton, M. C. RAYNER (*Empire Cotton Growing Rev.*, 16 (1939), No. 3, pp. 171-179).—A brief review of existing knowledge regarding mycorrhizal types and their relationships with various types of plants and various soil constituents. The types associated with crop plants, such as cotton, are discussed. The need is pointed out for more extensive investigations on the significance of mycorrhizas in agriculture, particularly in the study of soil factors likely to promote healthy growth and maximum resistance to disease.

The relation of specificity of orchid mycorrhizal fungi to the problem of symbiosis, J. T. CURTIS. (Univ. Wis.). (*Amer. Jour. Bot.*, 26 (1939), No. 6, pp. 390-399, figs. 9).—From isolations of mycorrhizas from 23 orchid species collected in various habitats in the United States and Mexico, 10 *Rhizoctonia* species (2 new) were obtained. No evidence of specificity was found, but there appeared to be a correlation of fungus species with ecological habitat, though a few occurred under a wide variety of conditions. The results of symbiotic germination tests supported the theory of nonspecificity, since the fungi isolated from an orchid were in most cases unable to induce germination of seed of that orchid. From all the evidence at hand it is concluded that the symbiotic relationship is one of parasite and host, with the orchid deriving no benefit from the fungus in its roots.

Problems of structure, growth, and evolution in the shoot apex of seed plants, A. S. FOSTER. (Univ. Calif.). (*Bot. Rev.*, 5 (1939), No. 8, pp. 454-470).—A review and theoretical discussion, with 66 references.

Structure and growth of the shoot apex of *Cycas revoluta*, A. S. FOSTER. (Univ. Calif.). (*Amer. Jour. Bot.*, 26 (1939), No. 6, pp. 372-385, pl. 1, figs. 15).

The point of origin of the blossom-inducing stimulus, R. H. ROBERTS and B. E. STRUCKMEYER. (Wis. Expt. Sta.). (*Science*, 90 (1939), No. 2323, p. 16).—“The variable responses to grafting and to donor branches depending upon the flowering habit of the species and the effects of a ‘temperature girdle’ and banding

in causing blossoming indicate that the stem of the plant plays a part in the appearance of blossoms as well as does a leaf-formed hormonelike substance."

Development of megagametophyte in *Erythronium albidum*, D. C. COOPER. (Wis. Expt. Sta.). (*Bot. Gaz.*, 100 (1939), No. 4, pp. 862-867, figs. 16).—This is a cytological and embryological study, with 14 references.

Phloem of white pine and other coniferous species, L. B. ALBE and A. S. CHARTS. (Univ. Minn. and Calif.). (*Bot. Gaz.*, 100 (1939), No. 4, pp. 695-722, figs. 17).—Cambium division in white pine is said to start in Massachusetts as early as February in some years, and to be rapid during May, while phloem differentiation may lag until late summer or early fall and daughter cells may remain in various stages of maturity through the winter. The structure and development of the sieve tubes were studied in detail and are described. White pine phloem contains no fibers, and secondary wall thickening occurs in the sieve tubes. Other coniferous genera have phloem fibers, and secondary wall thickening is confined to these elements, which are lignified. Protoplasmic connections in the white pine sieve areas are slender, solid, and fibroid in structure throughout the functioning period, and those of redwood are even more slender. The picture of the functioning of sieve tubes in conifers developed in this study is said to offer little support to theories of phloem transport requiring protoplasmic streaming or a high activity state in the mature sieve tube cytoplasm. There are 22 references.

Relation between chromosome number and stomata in *Coffea*, C. M. FRANCO (*Bot. Gaz.*, 100 (1939), No. 4, pp. 817-827, figs. 2).—The number of stomata was found to decrease inversely with the chromosome number, and size of leaf had no influence on stomatal number. The area of stomatal openings varied with the species and directly with the number of chromosomes. In general, the subsidiary cells contained a large oil drop. In some varieties, especially those of the *C. excelsa* group, green pigmented granules, like chloroplasts, were found in cells of the lower epidermis.

Photoperiodic responses of dill, a very sensitive long day plant, K. C. HAMNER and A. W. NAYLOR. (U. S. D. A. et al.). (*Bot. Gaz.*, 100 (1939), No. 4, pp. 853-861, figs. 3).—Of the seedlings from commercial dill seed used, ± 2 percent flowered soon after germination if grown under 9-hr. photoperiods, while the rest continued as rosettes for 11 mo. at the same photoperiod. Vegetative plants transferred from short to long photoperiods flowered after exposure to as few as four long photoperiods. When vegetative plants maintained on short photoperiods were transferred to continuous light for a period up to a 132-hr. total and then returned to short photoperiods, the subsequent rate of stem elongation was roughly proportional to the number of hours under continuous light. The critical photoperiod under ordinary greenhouse conditions was 11-14 hr. Exposure of a single leaf to long photoperiod, with the rest of the plant on short photoperiod, proved sufficient to induce the whole plant to flower.

The effect of temperature on the photoperiodic response of spinach, J. E. KNOTT. (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), p. 554).—An abstract.

The effects of ultraviolet radiation on spores of the fungus *Aspergillus niger*, P. A. ZAHL, L. R. KOLLER, and C. P. HASKINS (*Jour. Gen. Physiol.*, 22 (1939), No. 6, pp. 689-698, figs. 5).—The survival ratio was measured as a function of total incident energy for wavelengths of 2,537, 3,022, 3,129, and 3,650 a. u. The effect of humidity on killing the spores by ultraviolet radiation proved negligible. A delay in germination from irradiation was found. The Bunsen-Roscoe reciprocity law was found to hold within the limits of the radiation intensities studied. Certain induced morphological changes were noted. There are 23 references.

Carbohydrate transformations in leaf blades, with special reference to sucrose synthesis, O. A. LEONARD. (Miss. Expt. Sta.). (*Amer. Jour. Bot.*, 26 (1939), No. 7, pp. 475-484, figs. 4).—By supplying corn leaf blades with 6 percent glucose, the sucrose increased markedly during the 26-hr. feeding period, while glucose and fructose increased only slightly. Glucose, fructose, sucrose, maltose, and lactose solutions fed to sorghum and cotton leaf blades resulted in abundant accumulation of sucrose. Galactose and cellobiose resulted in a small increase of sucrose in sorghum. Cellobiose but not galactose resulted in some sucrose synthesis in cotton. There was no synthesis from *D*-mannose, *L*-xylose, *L*-arabinose, *D*-sorbitol, *D*-manitol, or *D*-dulcitol. Sorghum leaf blades fed glucose in CO₂ or N lost sucrose. Cabbage blades left in N lost by hydrolysis all their initial sucrose. Indoleacetic acid, neutralized with NaOH, at concentrations of 0.1 percent or higher prevented synthesis of sucrose from glucose, but not its hydrolysis. Various strengths of NaCN or KCN, KSCN, ethyl ether fumes, or invertase had little effect on sucrose synthesis. Drying corn leaf blades resulted in a slight increase in sucrose and fructose. Cabbage blades on drying synthesized large amounts of sucrose from the reducing sugars, this continuing until the blades had a moisture content of 8 percent but being prevented by heating to 72° C. Sucrose synthesis from glucose or fructose decreased with senescence in cotton blades, and it was synthesized less readily at 8° than at 30°–50°. Sucrose synthesis is said to be an anabolic process requiring energy, which is probably derived from certain stages in aerobic respiration. Active invertase is apparently not involved in this process.

The third study of water and cane ripening, C. E. HARRT (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.]*, 43 (1939), No. 2, pp. 145–158, figs. 8).—In continuation of this series (*E. S. R.*, 76, p. 605) the conclusions of the earlier studies were confirmed. Ratoons of plants used in the preceding study were used, and it was found that plants in soil at or below the wilting point may carry on photosynthesis, but the sugar made is very much less than under an adequate water supply. The sugar made under such conditions is stored rather than used, the result being a higher percentage of cane sugar in the dry-leaf cane. This gain in sucrose is said to be of physiological interest but probably not of economic importance since it is not all extracted in the juice. Small changes in moisture content of green-leaf cane affected the equilibrium between the simple sugars and sucrose. The sugar content of the dry-leaf cane was not static but was affected by such factors as time of day, water supply, and removal of plants from field to greenhouse.

Vitamins and the germination of pollen grains and fungus spores, W. C. COOPER. (*U. S. D. A.*). (*Bot. Gaz.*, 100 (1939), No. 4, pp. 544–552, figs. 2).—Lactoflavin (natural product) and ascorbic acid both proved highly effective in reducing germination of papaya pollen. Synthetic lactoflavin was only about half as effective as the natural product, which was found to contain boron, and this in turn induced pollen germination. It is thus concluded that natural lactoflavin may produce a combined effect. Nicotinic acid, indole-3-acetic acid, and the hydrochlorides of several amino acids were slightly active in inducing pollen germination, but apparently through a pH effect. Thiamin, nicotinic acid, ascorbic acid, carotene, lactoflavin, and a number of other substances induced germination of *Colletotrichum gloeosporioides* spores on corn meal agar. Only lactoflavin had this effect on oatmeal agar, but here the synthetic preparation was as active as the natural product. Amino acids induced germination in *Penicillium italicum* spores, while addition of lactoflavin to the amino acids materially inhibited it.

Vitamin B₁ in relation to meristematic activity of isolated pea roots, F. T. ANDICOTT (*Bot. Gaz.*, 100 (1939), No. 4, pp. 836-843, figs. 11).—"The action of vitamin B₁ as a growth hormone of roots is through an effect on meristematic activity rather than on cell elongation, which is the primary effect of the auxins. Cell elongation, differentiation, and maturation proceeded normally in the roots to which vitamin B₁ was not supplied, as far as could be observed, even though meristematic activity was greatly reduced"

Transplantation experiments with peas, H. H. E. HALLWARD and F. W. WENT. (U. S. D. A. et al.). (*Bot. Gaz.*, 100 (1939), No. 4, pp. 755-801, figs. 4).—Using a technic previously described (E. S. R., 79, p. 314), the anatomy and histology of the graft union of etiolated pea stems were studied at 5 and 9 days after grafting. In grafts growing very rapidly at first, very good approximation between the original vascular bundles of stock and scion were found. When approximation was poor the grafts grew slowly to begin with. In those which ultimately took, good development of new vascular connections between stock and scion was found, but little or none in unsuccessful grafts. Other tests indicated that only the initial growth rate and the period before the scion reaches its maximum growth rate are affected by whether the initial vascular approximation was good or poor. Thus in peas the ultimate growth of the scion is not affected by the type of grafting or the graft union.

The effect of various compounds upon straight growth of the *Avena* coleoptile, G. S. AVERY, JR., and G. B. SARGENT (*Amer. Jour. Bot.*, 26 (1939), No. 7, pp. 548-555, figs. 2).—In testing for ability to stimulate straight and curved growth of *Avena* coleoptiles, 180 compounds of widely different molecular structure were used, aliphatic, aromatic, and heterocyclic compounds and some of their derivatives being included. At the dilutions used, 37 stimulated growth, 50 inhibited it, and 93 had no apparent effect or gave inconsistent results. Only 10 of the active compounds, all previously well known, gave a clear-cut *Avena* curvature response.

The influence of certain nutrient conditions on catalase activity of apple seedlings, A. J. LOUSTALOT. (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), pp. 239-242).—In the experiments reported a deficiency of any of the three major elements tended to reduce catalase activity. While K and P deficiencies sooner or later depressed catalase activity, neither seemed to have as potent an influence as N. Catalase activity seems to be easily influenced by factors affecting the nutritive or physiological condition of the tissues. These preliminary results are suggestive, but more work is believed to be needed concerning the use of this enzyme as an indicator.

Effect of calcium deficiency on respiration of etiolated seedlings, W. R. MULLISON (*Bot. Gaz.*, 100 (1939), No. 4, pp. 828-835).—The effect of calcium deficiency on the respiratory rate of tops v. roots of etiolated seedlings of pea, squash, and corn, representing three chemical types of seed, was studied. Total respiration under plus and minus Ca nutrition was highest in corn, least in pea, and intermediate in squash, in all cases being less in the minus than in the plus Ca plants. Ca deficiency was most noticeable in the greatly lowered respiration of the minus Ca as compared with the plus Ca tops. Ca deficiency lowered the respiration of the pea and squash roots, but increased it in the corn roots. Roots of pea and corn respired more than twice as much as did their tops, while in squash it was nearly equal. There are 11 references.

Carbohydrate metabolism in relation to boron nutrition, R. H. WHITE-STEVENS. (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), pp. 537-543).—From the results reported and the manifold similar findings of others

(64 references) it appears that at least a tentative theory can be adduced for preliminary consideration. The fact that in boron-deficient plants carbohydrates are also lacking in meristem and root suggests that failure to function is due to lack of adequate energy, supplied normally by respiration of carbohydrates. This applies particularly to roots, where plenty of available energy is required to effect absorption of soil minerals against an osmotic and diffusion gradient, in defiance of the Donnan equilibrium. This slowing up of physiological function is apparently followed by an actual respiration collapse within the cells, resulting from a lapse in the carbohydrate supply.

Boron as a plant nutrient: A bibliography of literature published and reviewed, July 1938 to December 1938, inclusive (with index), D. H. JAMESON (Washington, D. C.: Amer. Potash Inst., Inc., 1939, Sup. 1, pp. [2] + 40 + VI).—Additions to the bibliography previously noted (E. S. R., 80, p. 459).

Leaf growth factors.—II, The activity of pure substances in leaf growth, D. M. BONNER and A. J. HAGEN-SMIT (Natl. Acad. Sci. Proc., 25 (1939), No. 4, pp. 144-153, fig. 1).—Studies of the activities of pure substances in the leaf test (described) indicated that one general class of compounds apparently possesses activity, viz, the purines, with adenine having the highest activity of any tested. It is emphasized that factors other than adenine or any single purine are involved in leaf growth, so that it is not surprising that the growth of etiolated pea seedling leaves was not very great. By increasing the growth rate of the leaves under normal conditions to an extent shown by the adenine leaf test, the other necessary factors will be formed in greater amount, resulting in further increased growth rate of the leaves. This increased leaf surface in turn would indirectly cause increased stem and root growth.

Production of growth substance by bacteria in media containing specific organic and inorganic nitrogenous compounds, P. R. BURKHOLDER (Univ. Mo.). (Amer. Jour. Bot., 26 (1939), No. 6, pp. 422-428, fig. 1).—Substances inducing *Arca* coleoptile growth curvatures were found in cultures of *Aerobacter aerogenes* and *Escherichia coli* grown on glycerol-mineral salts-agar in which the sole nitrogen source was KNO_3 , NH_4Cl , or any one of 17 amino acids. Uninoculated media remained inactive, except for tryptophane agar which showed some activity after autoclave sterilization. It is deemed probable that different substances having the physiological properties of auxins may be synthesized by micro-organisms in ways other than by the well-known conversion of tryptophane.

A new growth substance, β -naphthoxyacetic acid, S. C. BACSON (Amer. Jour. Bot., 26 (1939), No. 6, pp. 415-418).—The properties of this acid are described, and its synthesis and tests of its activity at various concentrations in lanolin paste on intact stems and leaves of *Ocimum basilicum*, *Mimosa pudica*, *Eranthemum nervosum*, and *Lycopersicon esculentum* are detailed. Sodium and potassium β -naphthoxyacetate also proved to be active.

Physiological differentiation in *Astragalus* with reference to selenium, S. F. and H. M. TRELEASE (Amer. Jour. Bot., 26 (1939), No. 7, pp. 530-535, figs. 6).—*A. racemosus* in solution and sand cultures was greatly stimulated by Se as selenite at 0.33-9 p. p. m., confirming earlier tests (E. S. R., 79, p. 174) in suggesting that Se may be an essential microtrophic element for this species. On the other hand, *A. crassicaarpus* was not stimulated but was poisoned by a selenite concentration as low as 0.33 p. p. m. *A. racemosus*, having the higher tolerance, was able to accumulate correspondingly higher concentrations of Se from solutions of selenite. Greenhouse tests of growth in artificial media confirmed field observations in showing a physiological differentiation of *Astragalus* species into two groups, viz, (1) those seeming to require Se for development and so serving as indicators of seleniferous soil areas, and (2) those not utilizing Se.

Effect of sulphur dioxide on vegetation (*Ottawa: Natl. Res. Council Canada, 1939. pp. XI+477, pls. [57], figs. [55]*).—The work here described was originated in 1929 and carried on almost continuously for more than 8 yr. The results are set forth in the following scientific papers prepared for the Associate Committee on Trail Smelter Smoke: Sulphur Dioxide in the Atmosphere of Industrial Areas, by M. Katz (pp. 14-50); Symptoms of Injury on Forest and Crop Plants, by M. Katz, G. A. Ledingham, and A. W. McCallum (pp. 51-103); The Sulphur Content of Trees and Shrubs in Relation to Sulphur Dioxide in the Atmosphere, by M. Katz and A. W. McCallum (pp. 104-130); The Hydrogen Ion Concentration, Base Exchange Capacity, and Sulphate Content of Soils (pp. 131-164) and Hydrogen Ion Concentration and Sulphate Content of Water Supplies (pp. 165-173), both by M. Katz, F. A. Wyatt, and H. J. Atkinson; The Effect of Sulphur Dioxide on the Diameter Increment of Conifers, by F. E. Lathe and A. W. McCallum (pp. 174-206); Description of Plots and Apparatus Used in Experimental Investigations, by M. Katz, A. W. McCallum, G. A. Ledingham, and A. E. Harris (pp. 207-217); Fumigation Experiments on Conifers in Their Natural Habitat (pp. 218-248) and Fumigation Experiments on Transplanted Conifers (pp. 249-261), both by M. Katz and A. W. McCallum; Effect of Environmental Factors on the Susceptibility of Barley and Alfalfa to Sulphur Dioxide (pp. 262-297), The Stomatal Behavior of Fumigated Alfalfa (pp. 298-331), and Experiments on Yield of Barley and Alfalfa (pp. 332-368), all by M. Katz and G. A. Ledingham; Effect of Fumigation on Some Chemical Constituents of Barley, Wheat, and Alfalfa, by M. Katz and D. S. Pasternack (pp. 369-392); and Carbon Dioxide Assimilation and Respiration of Alfalfa Under Influence of Sulphur Dioxide, by M. Katz, G. A. Ledingham, and A. E. Harris (pp. 393-428); with an introduction (pp. 1-13) and a summary (pp. 429-447), by M. Katz and F. E. Lathe.

A case of correlative growth inhibition in plants, F. W. WENT (*Amer. Jour. Bot.*, 26 (1939), No. 7, pp. 505-512, figs. 2).—Occasionally after applying high concentrations of indoleacetic acid, but regularly with phenylacetic, cyclohexanecarboxylic, or γ -phenylbutyric acids, growth inhibition of the lower zones of an *Avena* coleoptile occurs, demonstrated by direct growth measurements or more easily by unilateral application of the substances to the cut surface of decapitated coleoptiles, when they show positive curvatures within 2½ hr. after application. This inhibition is an indirect effect of these substances, observable only in intact or decapitated plants. It is shown that the inhibition is due to removal of other growth factors from the zone of inhibition, which are then accumulated near the place of application of the active substance. Thus the effects of substances like phenylacetic acid on growth are due to a dual action, viz, they redistribute other growth factors, and then react with those other factors to give cell elongation. Some substances (cyclohexanecarboxylic and γ -phenylbutyric acids) possess only the property of redistributing other growth factors without directly affecting cell elongation. In one case, dibenzoyl peroxide, tests indicated that the growth inhibition caused by it was probably due to its effect on the food factor.

The inhibition of root growth by auxins, J. BONNER and J. B. KOEFFLI (*Amer. Jour. Bot.*, 26 (1939), No. 7, pp. 557-566, figs. 2).—Through comparisons of 21 analogs of indoleacetic acid, it is shown that the chemical specificity of the auxin inhibition of root growth is closely similar to the chemical specificity for auxin promotion of stem and coleoptile growth, since the substances relatively highly active in the *Avena* and pea tests are also highly active in inhibiting root growth while those little active in promoting stem growth are also little active

in inhibiting root growth. The relative activities in root inhibition of the 21 auxin analogs studied were similar to but not identical with relative activities of the same substances on stem growth. Indoleacetic acid was more active in inhibiting root growth in media at pH 4 than at higher alkalinities. The relation of pH to auxin activity thus resembles the known relation between pH and auxin promotion of stem growth. It is shown that the inhibitory effect of auxin on root growth cannot be offset significantly by supplying the root with large excesses of the materials needed for root growth. In root inhibition the auxin thus seems to act directly on the root cells rather than on the mobilization or transport of other growth substances.

GENETICS

Breeding of resistant races of cultivated plants, T. ROEMER, W. H. FUCHS, and K. ISENBECK (*Die Züchtung resistenter Rassen der Kulturpflanzen. Berlin: Paul Parey, 1938, pp. [8] + 427, pls. 2, figs. [36]*).—This monograph discusses the necessity for such breeding, the biological bases and types of resistance, its inheritance, methods of breeding for resistance, and applications to specific diseases (pp. 125–419). Literature references for the various sections and a general bibliography are provided.

Inheritance studies in the interspecific cross *Solanum demissum* Lindl. × *S. tuberosum* L., C. L. BECKER. (Minn. Expt. Sta. and U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 59 (1939), No. 1, pp. 23–39).—The inheritance of several characters was studied in *S. demissum* × *S. tuberosum*. *S. demissum* is a small, prostrate, late-maturing species with narrow cotyledons, small leaves, long stolons, many small tubers, and 72 chromosomes. *S. tuberosum* is a large, erect, early maturing, frost-tender selection with wide cotyledons, medium-sized leaves, short stolons, many medium-sized tubers, and 48 chromosomes.

The 60-chromosome hybrids between these species showed considerable irregularity in meiosis, nonoriented and lagging chromosomes being usual. Three of 15 plants raised were fertile enough to produce F_2 families, one of which was practically identical with *S. demissum* in morphological characters and was uniform. The other two F_2 families approached *S. tuberosum* in morphological characters and were variable. Chromosome counts in 15 of the plants of 1 family ranged from 48 to 58. In cotyledon measurements, stem diameter, heat injury, maturity, frost injury, stolon length, number of tubers, and weight of the largest tuber, these F_2 families ranged from the extremes of the 2 original parents, with the means falling halfway between the parent means. Height of mature plants and internode length of the F_2 families resembled *S. demissum* more, while the weight of the crop was similar to that of *S. tuberosum*. Terminal leaflets and mature leaves were larger than those of either parent.

The induction of polyploidy in *Nicotiana* species and species hybrids by treatment with colchicine, H. H. SMITH. (U. S. D. A.). (*Jour. Hered.*, 30 (1939), No. 7, pp. 290–306, figs. 10).—A number of *Nicotiana* species and species hybrids were subjected to meristem treatments with 0.4 percent colchicine and seed treatments with 0.2, 0.4, and 0.8 percent colchicine, and polyploid forms were obtained. Autotetraploids of *N. rustica*, *N. tabacum*, and *N. glauca* were characterized by smaller plant habit, smaller and thicker leaves with larger stomata, larger pollen, and increased pollen sterility compared to the diploids. Polyploids of *N. rustica* and *N. tabacum* had larger seed than the diploids. Allotetraploids of the sterile F_1 s (*N. tabacum* × *N. glauca*) and (*N. tabacum* × *N. sylvestris*) were fertile, had wider and thicker leaves with larger stomata, and were similar to the undoubled forms in growth habit. Allotetraploids of the

dwarf hybrid, *N. glutinosa* × *N. glauca*, showed a marked increase in plant vigor, leaf size, and pollen fertility over the F₁. Hyperpolyploids, obtained from doubling chromosomes of some *N. rustica* × *N. tabacum* hybrid segregants, differed from sister plants in smaller plant habit, smaller and thicker leaves with larger stomata, and increased pollen fertility. Seed and polyploid offspring were obtained from *N. rustica*, *N. tabacum*, *N. rustica* × *N. tabacum* hybrids, *N. tabacum* × *N. glauca*, and *N. tabacum* × *N. sylvestris*.

Barley correlation values from six States, comparing chemical values, J. C. IRELAND and H. O. GRAMANN. (Okla. Expt. Sta.). (*Cereal Chem.*, 16 (1939), No. 3, pp. 361-365).—The multiple correlation data of hydrolyzed solids, total nitrogen, catalase, diastase, and weight per 1,000 kernels are presented for barley varieties from six States. The coefficient of multiple correlation was of doubtful significance. Correlations of 1,000-kernel weights with total nitrogen and diastase estimations were generally negative.

Sex intergrades in dioecious maize, D. F. JONES. (Conn. [New Haven] Expt. Sta.). (*Amer. Jour. Bot.*, 26 (1939), No. 6, pp. 412-415).—Three families of dioecious corn originating from a combination of known mutant types and propagated for nine generations each produced some individuals with a varying degree of male characteristics in the female plants and female characteristics in the male plants. The families differed in the number and character of these sex-intergrades and responded to selection. Sex expression in this material was relatively uninfluenced by the normally fluctuating environment and appeared to be governed by internal factors capable of segregation and recombination.

[Papers on genetics, reproduction, and lactation in dairy cattle] (*Jour. Dairy Sci.*, 22 (1939), No. 6, pp. 436, 437, 458, 459, 466-471, 475, 476, 478, 479, 488).—Brief abstracts are given of the following papers on these subjects presented at the 1939 meeting of the American Dairy Science Association: Recent Advances in the Endocrinology of Milk Secretion, by C. W. Turner (pp. 436, 437), and Artificial Insemination of Dairy Cows, by H. A. Herman and A. C. Ragsdale (pp. 466, 467) (both Mo. Expt. Sta.); Anatomical and Physiological Changes in the Pituitary Gland in Vitamin A Deficiency, by T. S. Sutton (pp. 458, 459) (Ohio State Univ.); The Inheritance of the Condition for a White Head in Holstein-Friesian Cattle, by L. O. Gilmore, W. E. Petersen, and J. B. Fitch (pp. 467, 468) (Univ. Minn.); The Inheritance of Fertility in Dairy Cattle, by A. Spielman and I. R. Jones (p. 468) (Oreg. State Col.); Analyses of Dairy Herd Breeding Records, by S. W. Mead and W. M. Regan (pp. 468, 469) (Univ. Calif.); Increasing Production in Institutional Herds, by A. L. Beam, C. S. McLearn, and A. A. Borland (pp. 469-471) (Pa. State Col.); Progress and Prospects of Organized Artificial Insemination of Dairy Cattle, by E. J. Perry (pp. 475, 476), and Influence of Disease in Dairy Cattle Breeding Programs, by G. E. Taylor (pp. 478, 479) (both Rutgers Univ.); and The Relation of the Posterior Hypophysis in the Maintenance of Lactation in Hypophysectomized Rats, by E. T. Gomez (p. 488) (U. S. D. A.).

Experiments in breeding Holstein-Friesian cattle for milk- and butterfat-producing ability, and an analysis of the foundation cows and of the first outbred generation, M. H. FOHRMAN and R. R. GRAVES (*U. S. Dept. Agr., Tech. Bul.* 677 (1939), pp. 82, figs. 14).—An analysis and discussion is given of the milk and butterfat production records of the 19 foundation cows having living ♀ progeny sired by the proved sire Denton Colantha Sir Rag Apple in the Beltsville herd and the production records of the daughters. When the 32 daughters that had normal records were compared with their dams, the unweighted average production of the dams was 23 lb. of milk and 1 lb. of

butterfat more than the daughters, indicating that the sire's hereditary level of production was definitely below that of the highest-producing dams to which he was mated but above that of the lower-producing dams. The foundation cows to which this sire was mated were slightly more persistent as milk producers than his daughters. Data are also presented on the breeding records, live weights, and conformation of the dam and daughter groups.

Crossbreeding hogs for pork production, J. L. LUSH, P. S. SHEARER, and C. C. CULBERTSON (*Iowa Sta. Bul. 380 (1939), pp. 81-116, figs. 6*).—An analysis of data regarding birth weights, size of litter, mortality, gains, and feed consumption of more than 1,600 crossbred and purebred pigs involving the Poland China, Duroc-Jersey, Yorkshire, and Danish Landrace breeds showed that crossbred pigs were more vigorous from birth to weaning, averaged heavier in weight, litters were larger, and gains were more rapid with a smaller feed requirement per unit of gain than purebreds. Early comparisons were made between pigs produced in double matings. Crossbred sows were efficient pig producers when backcrossed to one of the parent breeds or when crossed with a third breed, and the pigs compared favorably with those of the first cross. Possible advantages are suggested for the use of crossbred sows because of their increased vigor, but such sows must be mated with a purebred boar if satisfactory results are to be maintained.

On the variability and inheritance of colour and pattern in the sable (*Martes zibellina* L.), [trans. title], A. L. PONOMAREV (*Zool. Zhur. (Zool. Jour.), 17 (1938), No. 3, pp. 482-504, figs. 7; Eng. abs., pp. 503, 504*).—Study of the inheritance of color and pattern variability in sables indicated that white paws and white tip on the tail were probably due to the same recessive gene, whereas white head was determined by another recessive factor. Variations in the normal sable color from light sandy to coal black seemed due to a number of genes affecting variations in the color of the underfur tips and intensity and distribution of the long hairs. The presence of gray hairs behaved as an incomplete dominant, with age having little effect. There are two types of throat patches with several variations.

The genetics and physiology of lethal anemia in the rat, N. E. SMITH and R. DOGART. (Cornell Univ.). (*Genetics, 24 (1939), No. 4, pp. 474-493, figs. 15*).—A more complete account is given of the recessive autosomal lethal anemic condition in the rat previously noted (E. S. R., 78, p. 768). Matings of heterozygotes produced 534 normal and 179 anemic progeny. The grams of hemoglobin per unit of blood, span of life, and fertility were not significantly different in homozygous and heterozygous normals. Anemics had about one-third the normal red cell count and amount of hemoglobin. However, the leucocytes were increased from 2,700 in normals to 10,000 per cubic millimeter of blood in anemics. Variations from normal were also noted in the differential white cell count, chemistry, and histology of the blood and organs. Inability of the bone marrow to assume fully its hemopoietic function at the time of birth, with some hemolysis of defectively formed red cells, seems responsible for the anemia. The condition did not respond to treatment with liver extracts, iron and copper solutions, or normal rat blood.

Linkage of pea comb and blue egg in the fowl, J. H. BRUCKNER and F. B. HURT. (Cornell Univ.). (*Science, 90 (1939), No. 2326, p. 881*).—Among 85 laying daughters produced by mating an Araucana ♂ (blue egg strain) with domestic hens, 18 single-combed birds laid white eggs and 15 pea-combed progeny blue eggs. Only 2 of the daughters with pea combs laid white eggs. There was thus less than 6 percent crossing over between these genes.

Effect of testosterone on pituitary and mammary gland, R. P. REECE and J. P. MIXNER. (N. J. Expt. Stas.). (*Soc. Expt. Biol. and Med. Proc.*, 40 (1939), No. 1, pp. 66, 67).—The daily administration of 200 γ of testosterone propionate to spayed ♀ rats augmented the lactogen content of the pituitaries about 40 percent without changing the pituitary weight, and induced an extensive development of the lobule-alveolar system.

Colchicine reactions in ventral prostate of castrated male rats following androgenic treatment, E. Z. BURKHART (*Soc. Expt. Biol. and Med. Proc.*, 40 (1939), No. 1, pp. 137–139).—Daily administration of testosterone propionate to castrated ♂ rats caused an increase in the mitotic cells in the ventral prostate from 36 to 44 hr. after injection. Colchicine injections at first arrested mitosis 6 hr. later and interfered with mitotic division thereafter.

Initiation of lactation in the albino rat with lactogen and adrenal cortical hormone, R. P. REECE. (N. J. Expt. Stas.). (*Soc. Expt. Biol. and Med. Proc.*, 40 (1939), No. 1, pp. 25–27).—By injection of suitable doses of lactogen with adrenal cortical hormone with or without glucose solution into pseudopregnant rats after ovariectomy and the removal of one mammary gland lactation was initiated. It seems that another hormone besides lactogen limits milk secretion before the effects of lactogen can be expressed.

Estrus-inhibiting effects of inanition, M. G. MULINOS, L. POMERANTZ, J. SMILSER, and R. KURZBOK (*Soc. Expt. Biol. and Med. Proc.*, 40 (1939), No. 1, pp. 79–83).—Starvation and injections with various chemicals and hormones causing a loss in weight resulted in the loss of recurring oestrous cycles in ♀ rats. Probably this effect was brought about through changes induced in the hypophysis.

Artificial insemination of dairy cows, H. A. HERMAN and A. C. RAGSDALE (*Missouri Sta. Bul.* 407 (1939), pp. 31, figs. 26).—Descriptions of methods of collecting semen and its use for artificial insemination of dairy cattle are reported and illustrated. Recommendations are given for the formation of an artificial breeding association.

Artificial insemination of chickens and turkeys, W. H. BURBOWS and J. P. QUINN (*U. S. Dept. Agr. Cir.* 525 (1939), pp. 13, figs. 8).—A successful technic for collection of semen and artificial insemination of hens and turkeys is described and illustrated.

FIELD CROPS

[Field crops experiments, 1915–38, on Indiana Station experiment fields and farms], A. T. WIANCKO ET AL. (*Indiana Sta. Circ.* 242 (1939), pp. 1–5, 8–19; 243, pp. 6–8; 244, pp. 5, 6–8; 245, pp. 3, 4; 246, pp. 3, 4; 247, pp. 4–7; 248, pp. 5, 6, 7, 8).—Reports covering various periods are made again (*Ill. S. R.*, 75, p. 767; 78, p. 619; 81, p. 638), including variety tests with corn (and hybrids), wheat, oats, barley, rye, alfalfa, and soybeans; crop rotations; effect of certain crops on yields of crops that follow; an experiment on the place in the rotation to apply manure; effects of methods of disposing of cornstalks on yields of corn and oats; a comparison of grain v. livestock farming; clover v. timothy for hay production; response of sweetclover to light applications of limestone drilled with the seed v. with the seed drilled on land receiving heavier amounts previously; fertilizer experiments with corn, wheat, alfalfa, and pasture; fertilizer placement for corn; cultural (including planting) tests with corn and with soybeans for hay and seed; comparison of corn and sunflowers for silage; and reinoculation of soybeans.

[Farm crops research in Mississippi] (*Miss. Farm Res. [Mississippi Sta.]*, 1 (1938), Nos. 1, pp. 3, 6, 8; 2, pp. 1, 2, 5, 6, 7; 3, pp. 3, 5, 6, 8; 2 (1939), Nos. 1,

pp. 2, 3, 4, 5, 6; 2, pp. 5, 6; 3, pp. 1, 2, 4, 5, 6, 7, 8; 4, pp. 1, 2, 3, 4-6, 7, 8, *figs.* 4; 5, pp. 2, 4, 6, 7, 8; 6, pp. 1, 3-6, 7, *figs.* 2; 7, pp. 3-5, 7, *figs.* 3).—The progress of experiments with different field crops is reported in brief articles as follows: Vol. 1. No. 1, New Sugarcane Shows Worth With 486 Gallons Sirup per Acre, by J. C. Robert; Care in Handling of Sweetpotatoes Given Added Significance, by W. S. Anderson; and Winter Legumes Add Nitrogen, Build Up Succeeding Crop Yields, by R. Coleman; No. 2, Hemp Yields High—Big Question Is Marker, by H. C. McNamara; High Relative Humidity Is New Ideal in Curing, Storing Sweetpotatoes, by W. S. Anderson; Inoculation Required in Growing Legumes, by W. B. Andrews; and Out-of-State Hybrids, Native Varieties Corn Compared by 3 Stations, by C. R. Owen; No. 3, Five-Year Summary of Cotton Variety Tests Gives Food for Thought, by J. F. O'Kelly; Lespedezas Lead All Forage Crops for Hay Growth in Hill Sections, by H. W. Bennett; Interplanting Soybeans With Corn Has Mixed Effect on Yield, by R. Coleman; and Paymaster Corn Leads Holly Springs Test; Vol. 2, No. 1, Chippewa Irish Potato Leads in Delta Test, by E. A. Currey; Early to Medium Planting Dates for Corn, Mean Highest Yields; Barnyard Fertilizer Shows Worth in Test for Cotton Production, by J. C. Robert; Paymaster Corn Leads in State College Test; and Cotton Fertilizer Studies by Holly Springs Branch Station Analyzed, by E. B. Ferris: No. 2, Extra Cotton Follows Nonacid Fertilizer, by J. L. Anthony and R. Coleman; Bushel of Oats per Pound Nitrogen Applied, Delta Tests Show, by R. Kuykendall; and Excessive Cotton Land Preparation Not Justified, by T. N. Jones: No. 3, Fertilizer Placement Contributes to Crop Yield, Experiments Show, by C. Dorman; Soybeans an Important Crop for Use on the Noncotton Acres by H. C. McNamara; Nitrogen Fertilizers Mean More Corn, by R. Coleman; Enough Nitrogen in Winter Legumes, by R. Kuykendall; Winter Legumes Best Plowed Under Prior to Maximum Growth, by I. E. Miles, T. N. Jones, and R. Kuykendall; Corn Varieties Best for State Areas, by C. R. Owen; Mamredo Selections Leading Soybeans, by J. F. O'Kelly; and Crotalaria Shows Merit in Fertilizer Tests, When Compared With Soys, by E. B. Ferris; No. 4, More, Better Grazing With Phosphates, by H. W. Bennett; Cotton Spacing—Plenty of Stalks Surest Way to Maximum Yields, by E. B. Ferris; Time to Consider Better Seed Supply, by J. F. O'Kelly; Weed Control Is Purpose of Cultivation, by T. N. Jones; Dairy Pastures at College Point Way to Successful Methods in Other Areas, by J. S. Moore; Sorghum Widely Grown Throughout Country for Forage, Ensilage, Sirup, by W. R. Perkins; Growing Sweetpotatoes, by E. A. Currey; Summer Legumes Occupy Farmers as Spring Planting Season Reaches Fullness—Fertilizer Requirements for Maximum Yields Include Phosphorus and Potash, Recommendations Made, by I. E. Miles, and Inoculation Needed for Some, Not Needed for Others, Commercial Cultures or Inoculated Soils Suitable, by W. B. Andrews and C. F. Briscoe; and Fall, Winter, and Spring Plowing Effects in Delta Seedbed Preparation; No. 5, Fertilized Cotton Benefits by Extra Supply of Nitrogen Applied as Side Dressing, by R. Cowart and W. B. Andrews; Quality Hay by Proper Methods in Curing, Handling, by T. N. Jones; Nitrogen, Chief Fertilizer Need of Corn—Side Dressing Applied Now, Good Method, by E. B. Ferris; 800 lb. 4-8-4 Fertilizer for Sugarcane, by J. C. Robert; Methods of Cotton Cultivation, by F. M. Caperton; "Buy Seed Out After Field Inspection" Recommendation of Delta Branch Station, by H. C. McNamara; When Cotton Follows Legume Crop in Delta Legumes Supply Enough Nitrogen, by R. Kuykendall; and Supplement Pastures for Long Grazing, by J. S. Moore; No. 6, Still Time to Plant Feed Crops; Growing Soybeans in the Yazoo-Mississippi Delta, by H. A. York; Soybean Varieties, by J. F. O'Kelly; and Fertilizer for Sorghum About as for Cotton, by W. B. Andrews and R. Cowart; No. 7,

Growing Soybeans, Part 2, Utilization, Breeding, Varieties, by H. A. York; and For Best Yields of Cowpea Hay Cut Full Bloom Stage, by H. W. Bennett.

[Field crops investigations in New Mexico]. (Partly coop. U. S. D. A.). (*New Mexico Sta. Rpt. 1938*, pp. 16-20, 21-26, 28, 29, 33-35, 43-45, 68, 69, 71, 73, 74, 76-78, 79-81, figs. ?).—Reports of progress are made from research with field crops (E. S. R., 79, p. 41) at the station and on outlying fields, including variety tests with winter- and spring-sown wheat and barley, corn, oats, grain sorghum, sorgo, millet, cotton, potatoes, sugar beets, alfalfa, soybeans, cowpeas, beans, and miscellaneous forage crops; trials of barley and winter legumes for green manure and of flax and rice; breeding work with barley, cotton, and pinto beans; cultural tests with potatoes; fertilizer experiments with barley, sugar beets, cotton, alfalfa, and potatoes; date of planting and plant bed experiments with sweetpotatoes; tests of different forms of sulfur for control of psyllid yellows and comparisons of mineral elements used as supplements with a standard (NPK) fertilizer for stimulation of plant vigor to resist this disease; seed treatments with wheat, barley, cotton, and corn; irrigation tests with Acala cotton; studies of the annual production of sugar beet seed, concerned with effects of preceding crops and green manures, and application of various fertilizers and manure; crop rotations; studies of the restoration of ranges by artificial revegetation; control of Johnsongrass by chlorates and burning; and control of soil blowing by cultural practices and sorghum varieties.

[Field crops research in Rhode Island] (*Rhode Island Sta. Rpt. [1938]*, pp. 11-17, 21-23, 24, 37-39, 43).—Progress results are reported from variety tests with corn, potatoes, and lawn and turf grasses; fertilizer experiments with potatoes, mixed hay, and lawn and turf grasses, particularly varieties and strains of bents; planting and source of magnesium tests with potatoes; production tests with Ladino clover; residual effects from different levels of fertilizer for truck crops, as shown by yields of mixed hay and potatoes; effects of crops on succeeding crops; crop rotations; response of pasture grasses to different lengths of day and levels of soil moisture; breeding work and inheritance studies with alfalfa; control of lawn weeds; chloropirin treatments on compost and seedbed soil for weed seed control; seed production of bentgrass varieties and strains; and comparison of Sudan grass, millet, oats, and winter rye for supplementary pasture.

The number of replicated small plot tests required in regional variety trials, J. B. HARRINGTON (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 4, pp. 287-299).—During 1935-37, 1,010 tests each comprising between 18 and 25 4-row plats of wheat or barley varieties replicated from 3 to 5 times were distributed on farms over an area of 100,000 sq. miles in Saskatchewan. Variance analyses on grain yield showed that this large number of tests was needed to reveal the comparative behavior of the varieties under the particular conditions existing in many different localities. Marked reduction in number of tests would probably have obscured some differences and made much of the information from the remaining tests of doubtful significance.

Formulas for finding estimates for two and three missing plots in randomized block layouts, W. D. BATEN (*Michigan Sta. Tech. Bul. 165* (1939), pp. 16).—The method given by Yates (E. S. R., 70, p. 36) is used to find explicit formulas for estimating two and three missing plots in randomized block layouts, and examples showing how to use these formulas are given. Part 1 on two missing values considers two missing plots in the same treatment, missing plots in the same block, and missing values in different treatments and blocks. Part 2 on three missing values deals with missing plots in the same treatment, missing values in the same block, two missing values in the same treatment

and two in the same block, two missing values in the same treatment—each in different blocks, two in same block—each in different treatment, missing values in different treatments and different blocks, and one missing value.

A modern statistical analysis for field experiments: The analysis of variance for simple factorial experiments, R. J. BORDEN (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.]*, 43 (1939), No. 2, pp. 73-114).—The non-technical discussion of the application of the analysis of variance presented shows by actual example how results from field experiments can be set up and examined for evidence that measured yield differences between treatments are really an effect of the treatments and not more likely due to chance. Plans and analyses for the simpler forms of factorial experiments are offered as a suggested improvement in experimental technique.

Major changes in grassland as a result of continued drought, J. E. WEAVER and F. W. ALBERTSON. (Univ. Nebr.). (*Bot. Gaz.*, 100 (1939), No. 3, pp. 576-591, figs. 9).—Many perennial grasses decreased markedly in abundance as a result of the great drought of 1934-37. Little bluestem (*Andropogon scoparius*), once a most important dominant, suffered great depletion and disappeared from some prairies. Bluegrass (*Poa pratensis*), big bluestem (*A. furcatus*), and Indian grass (*Sorghastrum nutans*) all became much less abundant on uplands. Most species of forbs, including those very deeply rooted, gradually succumbed to the continued drought until they were only from one-half to one-third of their former abundance. *Festuca octoflora*, *Bromus secalinus*, and other annual grasses which became very abundant after 1934 greatly decreased in quantity later, filling smaller interspaces rather than occupying large areas. Wild peppergrass (*Lepidium virginicum*), so serious in 1936-37, had distinctly disappeared. Other annual weeds were extremely abundant only during one or two seasons. The perennial *Aster multiflorus*, with rhizomes, spread so widely into drought-bared areas as to ruin many prairies for production of hay. *Erigeron ramosus* was almost equally widespread. Many forbs with fleshy storage organs, as *Oxalis violacea*, *Allium mutabile*, and *Tradescantia bracteata*, increased remarkably in abundance. Western wheatgrass (*Agropyron smithii*) occurred sparingly at the beginning of the drought but spread so widely as to occupy from one-half to three-fourths of many former bluestem prairies. Numerous native grasses and especially *Stipa spartea*, *Sporobolus heterolepis*, and *Bouteloua curtipendula* became far more abundant and important. The short grasses (*B. gracilis* and *Buchloe dactyloides*) greatly increased. Drought reduced the basal cover in true prairie from 50 to 66 percent. The lower layer of grasses and forbs was almost destroyed, and grassland types were much modified.

The nitrogen content of grasses as influenced by kind, frequency of application, and amount of nitrogenous fertilizer, R. I. MCNEILL and R. A. BROWN. ([Conn.] Storrs Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 5, pp. 383-398, figs. 4).—Effects of eight different nitrogen sources and frequencies and rates of application of Cal-Nitro on the nitrogen content of Kentucky bluegrass and Rhode Island bentgrass were studied for 1936 and 1937 as part of a broad pasture project (E. S. R., 75, p. 618). Only ammonium carbonate applied to pure stands of these grasses failed to result in significant increases in total nitrogen over untreated plots. The other nitrogen carriers did not differ much among themselves in this respect. Marked increases in total nitrogen in both grasses occurred only in the first cutting after Cal-Nitro was applied, and its influence was not evident after about a month. A single application in April produced its greatest effect in May, and then the nitrogen content fell rapidly and remained low for the rest of the season. When the

fertilizer was withheld until June or August, the highest point in total nitrogen for the season was reached in the succeeding cutting. Fourteen lb. of nitrogen applied six times during the season produced about the same increase with less fluctuation in average nitrogen content over no treatment as three applications of 28 lb. When 56 lb. of nitrogen were applied three times, the further increases obtained in average nitrogen contents were 0.30 percent in Kentucky bluegrasses and 0.32 percent in Rhode Island bent. Percentage recoveries of nitrogen indicated that Cal-Nitro, calcium nitrate, ammonium sulfate, and sodium nitrate were the more efficient carriers. When Cal-Nitro was applied at different times the greatest nitrogen recovery was obtained from plots treated only in April and the least from plots treated in August.

Response of certain perennial grasses to cutting treatments, C. M. HARRISON and C. W. HODGSON. (Mich. Expt. Sta. and U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 5, pp. 418-430, fig. 1).—When five grasses and a mixture of smooth bromegrass and alfalfa grown in 10-in. clay pots were cut weekly at 1-, 3-, and 6-in. heights, the species differed in amount of injury incurred by continuous close clipping and rated, beginning with the least injured, in the order Kentucky bluegrass, quackgrass, smooth bromegrass, with timothy and orchard grass about equal. The greatest total yields of top growth and of underground parts (roots and rhizomes) were usually obtained from plants allowed to go unclipped. Yields decreased with increase in severity of cutting. Smooth bromegrass did better in mixture with alfalfa than when grown alone.

Vegetational changes as a result of furrowing on pasture and range lands, C. J. WHITEFIELD and C. L. FLY. (U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 5, pp. 413-417, figs. 4).—Striking increases in yield of air-dry forage and quality of pasture vegetation as to desirable species followed pasture furrowing and contour listing on several projects in Texas.

Pasture yields and consumption under grazing conditions, R. F. FUELLEMAN and W. L. BURLISON. (Ill. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 5, pp. 399-412, figs. 7).—Calculated yields and consumption of pasturage at Urbana, Ill., 1935-37, showed that yield curves of pasture grasses parallel rather closely precipitation curves but are the reverse of temperature curves. When temperature rises grass yields tend to decrease. Alfalfa is rather uniformly productive throughout the grazing season. Kentucky bluegrass may have some serious defects, but excels in general adaptation, utility, and persistence. Bromegrass persistently outyielded other grasses studied and apparently is high in palatability, as indicated by curves of consumption and production, and has persisted remarkably well. If growth and consumption are a criterion of palatability, orchard grass seemed to rank almost equally with Kentucky bluegrass. Reed canary grass not relished by cattle, particularly when stemmy, may have a limited use for pasturage, particularly on land adapted to other pasture crops, although it may provide both hay and pasture on land subjected to periodic inundation.

Greenhouse studies of the effect of clipping the tops of alfalfa at various heights on the production of roots, reserve carbohydrates, and top growth, C. M. HARRISON. (Mich. Expt. Sta.). (*Plant Physiol.*, 14 (1939), No. 3, pp. 505-516, figs. 4).—When top growth of alfalfa plants was removed weekly at specified levels for 8 successive weeks, as compared with responses of uncut cultures, marked reductions were found in production of new top and root growth and root (starch) storage in cultures cut at 1 in. and somewhat lesser reductions in cultures cut at 2 in., whereas cutting at 6 in. interfered only slightly in these respects. The significance of these observations in management of alfalfa pastures (E. S. R., 81, p. 505) is pointed out.

Differential survival of alfalfa strains under an ice sheet, R. A. BRINK, W. KELLER, and C. EISENHART. (Wis. Expt. Sta. and U. S. D. A.). (*Jour. Agr. Res.* [U. S.], 59 (1939), No. 1, pp. 59-71, figs. 4).—Ice sheets which form on the land when rain falls at freezing temperatures often damage alfalfa greatly in Wisconsin and adjacent States. An ice sheet (intermediate in severity) during January and February of 1937 provided an opportunity to study the reaction of alfalfa to such injury in a plat at Madison, Wis., containing 42 strains, many of which were self-fertilized selections from Grimm or their hybrids. The parental lines had been selected on the basis of cold resistance as measured by artificial freezing. Both Grimm and Hardigan alfalfa served as checks. The mortality on the plat averaged 42 percent, with values for individual strains ranging from 12 to 96 percent. Significant differences in survival between strains occurred and, furthermore, several strains were more resistant than either Grimm or Hardigan. Strains of hybrid origin were more resistant than their inbred parents. Since the reaction of alfalfa strains to an ice sheet depends upon the severity of the ice sheet complex, the authors feel that under more severe conditions significant differences established in the present study would doubtless be obliterated.

Effect of artificial drying upon the germination of seed corn, T. A. KIESSELBACH. (Nebr. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 6, pp. 489-496).—Drying experiments with seed corn, 1937 and 1938, involving procedure similar to that of Harrison and Wright (E. S. R., 62, p. 629) showed an apparent inverse relation between drying temperature and minimum moisture content attained by the dried seed. After 5 days of drying at 112° F. the moisture approximated 5 percent, while at 107° it was about 6.5 percent. It seemed that little further desiccation would occur from prolonged exposure at these temperatures. Seed with initial moisture content up to 30 percent and reduced to as low as 5 percent by drying for 5 days at 112° showed no unfavorable effects on field stand or seedling growth. When dried at 112° no significant differential injury appeared among 26 representative hybrids ranging from 16 to 38 percent in moisture content.

Timely and suitable drying of seed corn with heated air under forced draft may remove the freezing injury hazard, facilitate early harvest, storage, and processing, and avoid injury to seed viability or field performance. With such artificial drying, reduction in moisture content to from 12 to 13 percent at a range of from 105° to 110° is recommended except that temperature be held as low as 105° when the initial moisture content approaches 50 percent. Prolonged drying at safe temperatures to as low as 5 percent moisture is not harmful, although not practical. Insufficient drying subjects the seed to later loss of weight and possible deterioration in storage. The moisture content permissible for safe processing and storage ranges from 5 to 14 percent. The drying period needed to reduce ear corn to a safe moisture content varies with the initial moisture content of grain and drying temperature, approximately 1, 2, or 3 days for corn containing 20, 30, and 50 percent moisture, respectively, provided the air is changed enough.

Composition of bark and inner part of roots of the cotton plant, L. E. HESSLER, D. R. EGGLE, N. E. RIGLER, and J. E. ADAMS. (U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 6, pp. 528-540, figs. 2).—In continued studies (E. S. R., 80, p. 762), the bark was separated from the stele of roots of cotton plants grown on Wilson clay loam soil under various fertilizer treatments. Under experimental conditions covering the period from early square formation to early opening of bolls, the bark was found to be particularly rich in the labile carbohydrate and dialyzable nitrogenous constituents. The inner por-

tion of the root contained more polysaccharides and dialyzable and nondialyzable phosphates. The latter constituents increased when phosphates were added to the soil. All nitrogen fractions in the root parts, especially the cathode-nitrogen constituents in the bark, were influenced by the composition of the fertilizer used. The ketose sugars appeared to be important in the physiology of the cotton plant.

The response of lespedeza to lime and fertilizer, R. E. STITT. (U. S. D. A. and N. C. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 6, pp. 520-527 figs. 2).—Korean lespedeza did not respond significantly to lime and fertilizer and Kobe lespedeza responded only slightly to lime when grown on Cecil loam receiving complete fertilizer in the previous season. These varieties and common lespedeza and *L. sericea* responded to phosphate and lime on unfertile Cecil gravelly loam. The calcium and crude protein contents of Kobe and Korean plants growing on this soil were increased by addition of both lime and superphosphate, and their phosphorus contents rose in response to superphosphate. Under conditions of low phosphate availability, Kobe and Korean endured drought better than common lespedeza, which seemed unable to survive with the fertility level provided. *L. sericea* with its perennial root was not affected by drought.

[Potato research in Ohio] (*Ohio Veg. and Potato Growers Assoc. Proc.*, 24 (1939), pp. 5-18, 30-46).—These papers include Potato Demonstration Results in 1938, by E. B. Tussing (pp. 5-9) (Ohio State Univ.); Fertilizers for Early Potatoes, by J. Bushnell (pp. 9-14), and Factors Affecting Marketability of Ohio Potatoes, by C. W. Hauck (pp. 30-34) (both Ohio Expt. Sta.); Potato Varieties Better Suited to a Specific Set of Growing Conditions (pp. 14-18) and Variability in Cooking Quality in Potatoes (pp. 42-46), both by F. J. Stevenson (both U. S. D. A.); and Damage to Ohio Potatoes by Digging Machinery, by E. B. Tussing, E. A. Silver, and C. W. Hauck (pp. 34-42) (Ohio State Univ. and Ohio Sta.).

Soil management for potatoes, G. M. GRANTHAM, C. E. MILLAR, and A. H. MICK. (Partly coop. U. S. D. A.). (*Michigan Sta. Spec. Bul.* 299 (1939), pp. 31, figs. 2).—Information is given on the soil type and plant food needs and the status of the potato crop in Michigan, together with a report on fertilizer experiments conducted 1923-38 on 70 farms. In general, potatoes are grown on sandy loam and loam soils less fertile than the better soils.

Manure supplemented with complete commercial fertilizer, as 4-16-8, is deemed excellent for potatoes. Large increases in yields resulted in Montcalm County in 1928 wherever manure or commercial fertilizer was applied, but highest increases were obtained where both were used.

Fertilizer of 4-16-8 or similar formulas gave yield increases consistently among the highest produced on different soil types and under the varied weather conditions encountered. Fertilizer containing more potassium in relation to phosphorus, as in a 3-12-12 mixture, often gave as good or better yields than the 4-16-8, especially on the sandier soils. Fertilizer with as much or more potassium than phosphorus tended to delay maturity and often resulted in immature tubers at digging time. Applications of about from 500 to 600 lb. per acre were found most advisable, although larger yield increases were often obtained with heavier rates.

When placed in bands on both sides, on the level or a little deeper than, and about 2 in. from the seed, fertilizer resulted in slightly better average yields than the same quantity applied in other locations. Fertilizer mixed in the soil around the seed delayed sprout emergence, which, however, was often hastened by fertilizer applied in bands 2 in. to the sides of the seed. Under irrigation at Lake City, heavier amounts of fertilizer were used efficiently, and

applications could be made closer to the seed piece without resultant injury. When fertilizer was not applied near the seed at planting, application with an attachment to the cultivator at first cultivation proved advisable.

Tillering ability of sorghum varieties, J. B. SIEGLINGER and J. H. MARTIN. (U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 6, pp. 475-488, figs. 2).—Number of stalks per plant was determined in 105 varieties of sorghum grown at Woodward, Okla., 1930-37, in rows in which plants were spaced at about 7 and 36 in. apart. Stalks produced per plant in the 36-in. spacing by the various sorghum groups averaged for hegari 4.23, feterita, 4.03, sorgo 3.20, mlo 2.97, kaoliang 2.10, kafir 1.74, and durra 1.47. The 6-yr. average number of stalks per plant in 79 varieties was 1.28 in the 7-in. and 2.39 in the 36-in. spacing. Some varieties produced no tillers in certain seasons, while one variety averaged 6.8 stalks per plant in the 36-in. spacing in 1936. Varietal rank in number of stalks per plant was very similar in the two spacings, except when spacing was not uniform, although varietal differences were smaller in the 7-in. spacing. Small variations from average spacing had little effect on number of stalks per plant in kafirs and other varieties producing few tillers but were important in many varieties that tiller freely. Hegari produced a considerable number of tillers in all seasons and in both spacings. Dwarf Yellow and certain other milos usually tillered freely, but tillering fluctuated more with environment than in hegari. The proper plant spacing for a variety evidently depends largely upon its tillering ability. Varieties that tiller poorly should be planted relatively thick.

A study of sorghum with reference to the content of HCN, C. J. FRANZKE, L. F. PUHR, and A. N. HUME (*South Dakota Sta. Tech. Bul.* 1 (1939), pp. 51, figs. 6).—The influence of heritable, environmental, and cultural factors on the hydrocyanic acid content of sorghum was studied 1933-38. HCN was recovered from sorghum plants by precipitation with silver nitrate. The aspiration method invariably recovered lower amounts and recovered no HCN from silage.

Varieties and strains of sorghum were found to vary in contents of HCN. The low-HCN strains were consistently lower in HCN content throughout the growth period than were the high-HCN strains. Genetic studies indicated that HCN content in sorghums is controlled by heritable factors, and that low HCN seems to be partly dominant over high HCN. Apparently, only one or two main factors and possibly several minor modifying factors are involved.

The relative amount of HCN in leaves and stems is not constant. The average HCN content in stems analyzed was only 12.37 percent of that in the leaves. Contents of HCN occurring in sorghums differed slightly at two different periods in the day; varied to some degree at the same stage in a selfed strain as between four locations; were higher at the shooting stage in slow-growing plants of both low HCN and high HCN strains on Orman clay than in faster growing plants on Barnes loam; were lower when phosphate, potassium, and stall manure were applied (except when with lime); and rose with the regular use of nitrogen. Increases apparent after green manure were probably because growth of green manure may have reduced available soil moisture, which might inhibit the rapid growth of sorghum. The HCN content from irrigated sorghum appeared to be decidedly lower than in that from dry land. HCN content dropped with increased soil moisture, and also appeared to be affected by atmospheric conditions.

Maximum HCN content evidently occurs early, at the eight-leaf stage, diminishes slowly until the blooming stage, and then more rapidly to a minimum at maturity. Apparently a gradual loss of HCN occurred in the sorghums during the drying process. The average HCN in 12 strains dried in shade diminished

generally from the earliest growth stage to complete maturity similar to green forage. HCN content in the sun-cured portions was invariably lower than that of comparable uncured and shade-cured samples. Strain differences were observed in losses of HCN in drying or curing.

The average percentage loss of HCN for all strains in 1934 and 1936 over 6 weeks of shock curing was 79.5. The HCN in sheaves from the outside tier of a shock put up just after harvest was lower after 6 weeks' curing than in either inside tier. Permitting sheaves to lie on the ground 3 days before shocking apparently reduced their content of HCN appreciably.

Freezing, though not a direct cause of increase in HCN content of sorghum, evidently results in a more rapid and complete liberation of HCN than is normally found in sorghum plants. This might explain certain cases of sorghum poisoning after heavy frosts, especially if animals have access to sorghum after freezing. Sorghum stored as silage lost part of its original content of HCN, although the losses varied widely. No correlation was seen between amounts of HCN and percentage of total sugar in the strains studied.

Whatever conditions of environment may promote normal and regular growth in sorghum plants evidently lead to minimum HCN content therein. Conditions which retard such normal development of sorghum plants, in greater or less degree, bring about corresponding increase in amounts of HCN in subsequent growth.

The soybean and soy industries, A. MATAGRIN (*Le Soja et les industries du soja*. Paris: Gauthier-Villars. 1939, pp. X+390, figs. 46).—This book considers in successive chapters (each with bibliography) the history and status of the soybean industry and its world commercial importance, botanical characteristics and cultural requirements, chemistry of the soybean, soybeans in food products, soybean oil and byproducts, vegetable lecithin, and vegetable casein and plastics from soybean meal.

The influence of space and arrangement on the production of soybean plants, R. G. WIGGANS. (Cornell Univ.). (*Jour. Amer. Soc. Agron.*, 51 (1939), No. 4, pp. 314-321, figs. 2).—The advantage of the solid drill (8 in.) method over rows wider apart (28 in.) when early maturing soybean varieties are used for the purpose of grain production was illustrated in tests with three soybean varieties, 1931-37. When Cayuga soybeans (E. S. R., 72, p. 42) were planted, 1934-37, about $\frac{1}{2}$, 1, $1\frac{1}{2}$, 2, 3, 4, and 6 in. apart in 8-, 12-, 16-, 24-, and 32-in. rows, gross yields showed that yield decreases with any and all increases in distance between rows; that a wide range in distance between plants in the row has little effect on production, although yield tends to be greatest with the thickest planting, and with a gradual falling off as spacing increases; that spacings greater than 3 in. within the row show significantly smaller yields than thicker rates; and that an acre yield of 40 bu. approaches the "ceiling" for this variety under central New York conditions. The net yields indicated that the thickest plantings within the rows do not give the greatest returns, and that the spacing within the rows giving the maximum yield varies from 3 in. apart in 8-in. rows to 1 in. apart in 32-in. rows. Optimum rates and spacings should be determined for both the different producing areas and for the soybean varieties to be grown. A variety has an optimum number of plants per unit area for maximum net increase, this being six plants per square foot for Cayuga.

International Society of Sugar Cane Technologists: Proceedings of the Sixth Congress (Baton Rouge, La.: Internatl. Soc. Sugar Cane Technol., 1939, pp. XXIII+1189, [pl. 1], figs. [322]).—The session of this Congress, held October 24 to November 5, 1938, at Louisiana State University, included general and

sectional meetings concerned with cultural and field practices, soils, diseases and insect pests, experimental technic, factory operation, and chemical control. Discussions followed most of the papers.

Papers of agronomic interest included *The Development of the Sugarcane Industry in Louisiana and the Southern United States*, by C. A. Browne (pp. 46-69) (U. S. D. A.); *Sugarcane Improvement Work in New South Wales*, by D. S. North (pp. 79-87); *Report of the Special Standing Committee on Description and Identification of the Original Cane Varieties*, by W. W. G. Moir (pp. 113-115); *Relative Usefulness and Variability of Vegetative Characters in Sugarcane Taxonomy* (p. 115) and *Illustrated Outline for Use in Taxonomic Description of Sugarcane Varieties* (pp. 116-127), both by E. Artschwager, and *Assembling and Evaluating Wild Forms of Sugarcane and Closely Related Plants*, by E. W. Brandes, G. B. Sartoris, and C. O. Grassl (pp. 128-153) (all U. S. D. A.); *On Certain Floral Characters in Sugarcane, I*, by N. L. Dutt, M. K. Krishnaswami, and K. S. Subba Rao (pp. 154-170); *Brief Description of a Crossing Lantern Used by the Sugarcane Research Station, Mauritius*, by A. de Sornay (pp. 170, 171); *Sugarcane Collection in New Guinea During 1937*, by C. G. Lennox (pp. 171-152) (Hawaii. Sugar Planters' Expt. Sta.); *Double Versus Single Planting*, by C. H. B. Williams and L. A. Forte (pp. 266-271); *Caneland Cultivation in Mauritius*, by A. N. Coombes (pp. 271-275); *Interplanting on Sugarcane to Paddy Rice*, by T. Fukuchi (p. 275-277); *Recent Soil Studies in Mauritius*, by P. Halais (pp. 278-284); *The More Important Soils of the Sugarcane District of Louisiana and Their Physical Characteristics*, by A. M. O'Neal and L. A. Hurst (pp. 284-295); *Preliminary Chemical Studies of Four Soil Types in the Louisiana Sugarcane District*, by N. McKaig, Jr., and L. A. Hurst (pp. 296-302); *Soil Fertility and Fertilizer Studies With Sugarcane in Louisiana*, by L. A. Hurst and R. L. Holmes (pp. 304-313); *Preliminary Studies on the Correlation of Cane Juice Analyses With Soil Analyses*, by R. L. Holmes (pp. 314-319); and *The Influence of the Soil on the Chemical Composition of Louisiana Sugarcane Juices*, by N. McKaig, Jr., and C. A. Fort (pp. 319-325) (all U. S. D. A.); *A Note on the Sugarcane Soils of British Guiana*, by R. R. Follett-Smith (pp. 326-333); *Stubble Deterioration*, by C. W. Edgerton (pp. 334-341) (La. State Univ.); *On the Influence of the Phosphorus Deficiency Upon the Vegetative Growth, Accumulation of Sugars, Nitrogen Content, and the Ash Constituents in the Sugarcane Plant*, by T. Saito and M. Kenjo (pp. 347-357); *Report of the Committee on Technique of Field Experiments*, by G. Arceneaux (pp. 387-390); *Portable Apparatus Used for Weighing Sugarcane in Agronomic Experiments in Louisiana*, by I. E. Stokes and R. T. Gibbens, Jr. (pp. 391-395); and *Improvements in the Methods and Equipment for Weighing Cane From Experimental Plots Used by the Soil Fertility Division of the U. S. Bureau of Plant Industry*, by R. L. Holmes and A. M. O'Neal (pp. 396-399) (all U. S. D. A.); *Cane Sampling Methods With Field Experiments*, by H. W. Kerr (pp. 399-403); *Border Competition in Sugarcane Variety Tests Under Louisiana and Georgia Conditions*, by G. Arceneaux, I. E. Stokes, B. A. Belcher, and R. T. Gibbens, Jr. (pp. 403-419) (U. S. D. A.); *An Outline of Recent Sugar Control Programs and Their Effect on the Louisiana Sugar Industry*, by M. Voorhies and W. M. Grayson (pp. 514-523) (La. State Univ.); *Mechanical Harvesting of Sugarcane in Hawaii*, by W. J. Maze (pp. 524-529) (Hawaii. Sugar Planters' Sta.); *Windrowing Cane for the Mill*, by C. L. Denley (pp. 532-534); *Land Preparation for Sugarcane*, by J. A. Gibb (pp. 536-543); *Notes on Labor-Saving Devices*, by H. T. Barr (pp. 544-548) (La. State Univ.); *Hawaiian Rapid Chemical Methods at Natal Estates, Limited, Mount Edge*

combe, by B. Campbell (pp. 617-629); The Laboratory Determination of Soil Fertility, by H. W. Kerr and C. R. von Stieglitz (pp. 629-639); Comparison of Soil Analyses With the Response of Sugarcane to Fertilization, by R. L. Holmes and L. A. Hurst (pp. 640-649), and Laboratory and Field Methods for Determining Fertilizer Requirements of Soils, by O. Schreiner and M. S. Anderson (pp. 650-663) (both U. S. D. A.); Some Studies in Soil Sampling Technique, by H. W. Kerr and C. R. von Stieglitz (pp. 664-672); A Preliminary Note on the Field Experimentation of the Cane Sugar Section, by J. M. Aguirre, Jr., H. Denley (pp. 714-717); Seedling Selection in Mauritius, by A. de Sornay (pp. 718-726); Sugarcane Varieties in Hawaii, by A. J. Mingseldorf (pp. 726-731) (Hawaii Sugar Planters' Sta.); Cane Hybridization Work in Coimbatore, by T. S. Venkatraman (pp. 731, 732); Studies in Experimental Technique: Plot Arrangement, by R. J. Borden (pp. 733-744) (Hawaii Sugar Planters' Sta.); A Study of the Relation Between Size of Field Sample and Experimental Errors of Juice Analysis and Sugar-Yield Determinations in Connection With Sugarcane Variety Tests, by G. Arceneaux, I. E. Stokes, B. A. Belcher, and R. T. Gibbens, Jr. (pp. 744-753), and A Study of the Number of Stalks of Cane Required for Accuracy in Sampling Experimental Plots, by R. L. Holmes and A. M. O'Neal (pp. 760-764) (both U. S. D. A.); Notes on Plot Technique, by H. W. Kerr (pp. 764-778); An Efficient and Compact Layout for Sugarcane Fertilizer Tests, by C. H. B. Williams and R. R. Follett-Smith (pp. 778-784); On the Arrowing Tendency of Sugarcanes Along the Edges of the Fields, by M. Yamasaki and H. Oda (pp. 793-795); The Behavior of Sugarcane in Relation to Length of Day, by G. B. Sartoris (pp. 796-801) (U. S. D. A.); Some Aspects of the Problem of Drought Resistance in Sugarcane, by H. Evans (pp. 802-807); Resistance to Inversion of Sucrose in Harvested Sugarcane in Louisiana, by J. I. Lauritzen, R. T. Balch, and C. A. Fort (pp. 809-818) (U. S. D. A.); The Composition of the Crude Chlorophyll of Cane Leaves and Its Relationship With Cane Growth, by C. E. Beauchamp and F. Lazo (p. 819-832); Suggested Ways and Means of Meeting New Economic Problems in the South African Sugar Industry, by P. Fowlie (pp. 833-839); Flood-Fallowing of Sugarcane Soils, by R. R. Follett-Smith (pp. 840-843); Deep Tillage Work in Louisiana Using the Gyrolette, by C. L. Denley (pp. 843-845); and Drainage of Peat Soils in the Florida Everglades, by B. S. Clayton (pp. 846-851) (Fla. Sta. coop. U. S. D. A.).

Interests of factory technologists and chemists were considered in papers noted on page 758, and those of economic zoology and entomology on page 812.

Timothy culture, M. W. EVANS, F. A. WELTON, and R. M. SALTER. (Coop. U. S. D. A.). (*Ohio Sta. Bul.* 603 (1939), pp. [1]+54, figs. 6).—Planting, fertilizer, and cutting experiments with timothy were made during different periods at North Ridgeville and also at Wooster, Ohio.

In seeding tests comprising rates from 1.25 to 20 lb. per acre, results indicated that 3 or 4 lb. may be a satisfactory rate with winter grain in the fall. Spring-sown with oats as a companion crop, timothy made slightly larger yields from 10 lb. than from 5 or 20 lb. of seed. In a number of tests somewhat higher hay yields containing a higher proportion of clover were obtained from spring than from fall sowings, both at a 10-lb. rate and in mixture with spring-sown red clover, but these yields usually were less than from 2.5 or 5 lb. fall sown or from split seedings (2.5 lb. in fall, 7.5 lb. in spring). Effects of different seeding rates upon the meadow diminished with age, and rate of seeding

and protein content of the hay were not related consistently. Sown alone, medium red clover outyielded timothy, but the yield of neither separately equaled that of the two combined.

At Wooster neither superphosphate alone or in mixture with potassium increased yields, but sodium nitrate with these materials increased acre yields of hay and protein. At North Ridgeville superphosphate alone and with potassium increased hay yields, chiefly through larger growth of volunteer clover. Hay on unfertilized plats averaged (5 yr.) 6.04 percent protein, and from 300- to 1,600-lb. applications of sodium nitrate increased the content from 0.58 to 2.55 percent, but no increase came from smaller rates. The second cutting averaged 7 percent as large as the first in yield, and its protein content averaged 9.96 percent on unfertilized land and exceeded 11 percent on heavily fertilized plats. Second crops were obtained only in 1931 and 1932 and both were rather light.

When sodium nitrate, 200 lb. per acre, was applied about October 1 and about every 2 weeks from March 15 to June 15, on the average the maximum came from April 15 treatment. October applications were nearly as effective as those from March 15 to May 1. Highest recovery of added nitrogen and highest protein yield were obtained from plats fertilized May 15. A second application of 200 lb. before harvesting increased the hay yield 375 lb., protein 0.74 percent, and protein yield 51 lb. Among nine nitrogen carriers compared, organic forms were somewhat less effective than the inorganics, which did not differ much in effects upon hay.

When timothy was cut for 5 yr. at six growth stages, the highest hay yield on unfertilized plats was obtained when the earliest heads were turning straw color, the highest protein percentage 8.6 at beginning of heading, and the highest acre yields of protein from fully headed to early bloom. Similar results were obtained on fertilized plats. For highest quantity and quality of hay combined, timothy evidently should be cut in early bloom.

Summer applications of sodium nitrate made before harvest increased hay yields and also percentages and yields of protein more in the plats cut early than in those cut late. Summer applications after cutting produced similar increases the next year in the yields of hay and protein but not in protein percentages.

When commercial grades were assigned to timothy cut at different growth stages, the earlier cuttings only graded Number 1 Extra Green, and the use of nitrogen slightly reduced the grade. Yields on uniform cuttings after the stage of cutting tests were ended showed that early cutting affected adversely the permanence of the meadow.

The haplocorms or bulbs continued to develop until about plant maturity, after which they began to decrease in weight simultaneously with appearance of new shoots.

Recommendations are made on production of timothy seed.

Some aspects of the physiology and nutrition of tobacco, W. W. GARNER (U. S. D. A. and N. C. and Md. Expt. Stas.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 5, pp. 459-471, figs. 4).—The necessity for developing a physiological approach to the tobacco fertilizer problem, particularly on light sandy and sandy loam soils, was demonstrated in tests with potash salts at Oxford, N. C., which resulted in the discovery (E. S. R., 48, p. 454) of magnesium deficiency in these soils, accompanied by characteristic deficiency symptoms in the crop. Chemical analysis of these soils and of tobacco they produced, supplemented by field tests, indicated that they may be as deficient in calcium, magnesium, and sulfur as in nitrogen, phosphorus, and potassium. In specific cases soil deficiency in all six elements was demonstrated by marked depression in yield, occurrence

of distinctive deficiency symptoms in the crop, and abnormally low content in the crop of the particular element withheld from the fertilizer. These soils are regarded simply as rather impure sand culture media, and it is not considered logical to apply to these soils carriers containing two or more essential elements, without compensating treatment, and attempt to evaluate results obtained with plants in terms of only one constituent element. With soils properly selected with respect to these criteria of mineral deficiency and with precaution of varying the supply of only a single essential element, excellent data were obtained on absorption by the plant in relation to increased supply of this element. By utilizing this plan of conducting "field sand cultures," consistent and significant results have been obtained in extensive physiological studies of effect of the nitrogen supply on growth and development phenomena, metabolism, and other internal relations, and on the chemical and physical properties of the cured tobacco leaf.

Drying and curing of bright leaf tobacco by means of conditioned air, A. H. COOPER, C. D. DELAMAR, and H. B. SMITH (Va. Polytech. Inst. Bul., 32 (1939), No. 6, pp. 28, figs. 8).—In the experimental application of air conditioning to the curing and drying of tobacco, drying rate curves for each period of the curing process were obtained over a wide range of constant conditions of temperature, humidity, and air velocity. Correlation of the curing curves indicated narrow limits of conditions for satisfactory curing and critical points beyond which poor quality of tobacco results. "From the results obtained, air conditioning improves the process by (1) reducing the time approximately by one-half, doubling the capacity of the barn; (2) production of uniform quality tobacco, completely eliminating loss from improper curing; and (3) considerable reduction in labor and fuel requirements." Another suggested advantage is reduction of fire hazard.

Effect of mutilation of wheat seeds on growth and productivity, W. J. SANDO. (U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 31 (1939), No. 6, pp. 558-565, figs. 2).—"When wheat is threshed, some of the grains are usually broken. This damage in very dry wheat frequently exceeds 2 percent and may amount to more than 10 percent. The value for seeding purposes of the germ end of broken grains is of interest to the farmer."

Planted in rows in the field at Arlington, Va., 1933-35, whole kernels of Dawson and Nittany winter wheats were superior to half and one-third (germ-end sections) kernels in germination and in subsequent plant survival and number of culms (with one exception), total weight, and grain yield per plant. Half kernels likewise were usually superior to one-third kernels. Half kernels with the cut ends capped with paraffin were superior to unparaffined half kernels except in seed germination and in percentage of seeds producing mature plants. In general, greenhouse experiments with Baart spring wheat confirmed the results from the field plantings of winter wheat.

Further studies upon the relative macaroni-making quality of a number of durum wheat varieties, D. S. BINNINGTON and W. F. GENDES (*Cereal Chem.*, 16 (1939), No. 3, pp. 384-392).—In an extension of earlier studies (El. S. R., 78, p. 480), 99 samples representing 11 standard varieties of durum wheat produced in western Canada, 1935-37, were milled into semolina and macaroni produced therefrom. Only Arnautka, Mindum, and Akrona produced macaroni of satisfactory commercial quality with a reasonable degree of consistency over the period. Weight per bushel and semolina yield were governed chiefly by environment, whereas protein and carotene were influenced more by variety. Significant positive intervarietal correlations were obtained only between wheat protein and semolina protein, wheat carotene and macaroni carotene, and semolina carotene

and macaroni carotene. Negative intervarietal correlations were found between wheat protein and wheat carotene and between semolina protein and semolina carotene. The results emphasized that no single analytical factor can be relied upon for the intervarietal prediction of macaroni quality, and the best index available is the color of finished product. Wheat carotene alone is deemed valueless for the intervarietal prediction of macaroni color.

Relative absorption of nutrients by weeds of arable land, B. N. and L. B. SINGH (*Soil Sci.*, 47 (1939), No. 3, pp. 227-235).—Analysis of *Chenopodium album*, *Arcemone mexicana*, *Launuca nudicaulis*, and *Oxalis corniculata*, with special attention to the concentrations of different essential elements at successive stages, showed that the absorption per plant increases throughout the life cycle, with decline in rate during the latter part. Gain in absorption per plant attains the maximum at preflowering, considered the stage of maximal absorption. At this stage for all weed species the different elements are absorbed in different quantities. On this basis the weed species were arranged into three groups. The group of weeds rich in nitrogen is the largest, weeds rich in calcium intermediate, and weeds rich in potassium the smallest. Most members of a family possess a greater affinity for a particular ion than for other ions, especially when individual genera are considered.

Relation of root reserves to control of European bindweed *Convolvulus arvensis* L., A. L. BAKKE, W. G. GAESSLER, and W. E. LOOMIS. (Coop. U. S. D. A.). (*Iowa Sta. Res. Bul.* 254 (1939), pp. 113-144, figs. 7).—Analyses of material collected from experiments involving various treatments showed that the reserves of the bindweed roots consisted largely of sucrose and a dextrin-like compound or group of compounds, while reducing sugars and true starch were less important. Acid hydrolyzable substances were not depleted in starving bindweed roots. Results with lead-precipitable gums were variable. Polysaccharide reserves were rapidly depleted in the surface roots (upper foot) under either fallowing or chlorate treatments. Sugar levels were more nearly maintained, presumably by upward translocation from the lower roots. The maximum percentage of reserves found in roots from 6 to 8 ft. deep were exhausted only after prolonged fallowing. The totals of either top or root growth of bindweed were not large, the maximum weight of roots recorded being 7,200 lb. per acre to a 17-ft. depth. Total sugar and polysaccharide reserves in the roots were less than 600 lb. per acre. Persistence of the plant under fallowing thus seemed due to the small quantity of reserves needed to regenerate new growth and to the slow rate of removal from the lower roots rather than to the presence of unusually large quantities of reserves. Chlorate treatments resulted in an immediate drop in root reserves, suggesting a direct effect upon respiratory rates or other processes in the treated roots. Total nitrogen, which does not decrease with respiration, showed a decline in fallowed plots which paralleled the drop in carbohydrates but increased in the chlorate-treated roots during the first season of treatment. The sucrose and the dextrin-starch series of polysaccharides were shown to be the important carbohydrates of all bindweed tissues in both total quantities and diurnal fluctuations. Analyses of total tissues gave evidence that the gradients of all substances assumed to be available for translocation were negative in every determination, being lowest in leaves, intermediate in stems, and highest in roots.

The worst weeds [trans. title], O. CARON (*Min. Agr. Procr. Québec Bul.* 103 (1937), pp. [2]+33, [figs. 44]).—Forty-four of the worst weeds in the Province of Quebec are described, with control measures.

Did these go thru your grain drill this spring? D. E. WEIMER (*Farm Res. [New York State Sta.]*, 5 (1939), No. 3, pp. 2, 4, figs. 2).—The content of different

weed seeds found in 49 dealer oats stocks and 40 farmer stocks in 1939 is tabulated. The most prevalent of 27 weeds were wild oats, wild buckwheat, wild mustard, quackgrass, yellow foxtail, and lamb-quarters.

HORTICULTURE

[Horticultural investigations by the Mississippi Station] (*Miss. Farm Res. [Mississippi Sta.]*, 1 (1938), Nos. 1, p. 6; 2, pp. 3, 8; 3, p. 2; 2 (1939), Nos. 1, pp. 6, 7, 8, fig. 1; 2, pp. 1, 2, 3, 4, 7, 8, figs. 2; 3, pp. 2, 6, 7; 4, pp. 2, 7, fig. 1; 5, pp. 1, 2; 6, pp. 1, 2, 6, 8, figs. 6).—Herein are presented general articles on the following subjects: Vol. 1, No. 1, strawberry growing methods, by T. E. Ashley; No. 2, fruit trees, vines, and ornamentals improved by grafting and budding, by S. J. Greer, and depth of surface soil has material effect on black locust growth, by E. G. Roberts; No. 3, tung trees respond to good treatment, by J. C. Robert: Vol. 2, No. 1, February best time for storing graftwood, by W. T. Mallory; Eckles, native apple, recommended for use in State home orchards, by C. H. Ragland; even a light fire is death to seedlings, by Roberts; and better fertilization and varieties—needs of pickle cucumber industry, by W. S. Anderson; No. 2, small fruit culture on State farms, by Ashley; propagation by cleft grafting and whip grafting easily done, by Greer and Mallory; Pontotoc pear named for home orchards, by Ragland; earlier tung income, more permanent trees, by triangular planting, by Robert; and new varieties sweet corn recommended, by C. R. Owen; No. 3, annuals and perennials for sun and shade, by F. S. Batson; springtime in orchard means spraytime; and higher yields from closer spacing of tomatoes for early market, by L. R. Farish; No. 4, pecan bark grafting, by Greer and Mallory, and native shrubs in Mississippi well adapted to home landscape planting, by Batson; No. 5, blueberries for home orchards in south Mississippi, by Ashley; No. 6, peach varieties listed for home orchards of State, by Ragland; summer training of fruit trees, by Ashley; and young- and boysenberries valuable additions to orchards and vineyards, by E. B. Ferris and Ragland.

[Horticultural studies by the New Mexico Station] (*New Mexico Sta. Rpt.* 1938, pp. 65-67, 70, 71-73, 75, 76, 78, 82-84).—Included are reports on studies relating to the time of blooming of various fruits; varieties of apples, pecans, tomatoes, chile peppers, sweet peas, spring bulbs, perennials, and other ornamentals and small fruits; time of planting lettuce; production of vegetable seeds; nature of irregular bearing of apples; and the effects of irrigation on the White Grano onion.

[Horticultural studies by the Rhode Island Station] (*Rhode Island Sta. Rpt.* [1938], pp. 17-20, 24-31, 39, 40).—Included are brief reports upon the results of studies of the fertilizer requirements of vegetables; strains and varieties of vegetables; staking of tomatoes; effect of hardening tomato plants on yield; use of growth-promoting substances in the propagation of ornamentals; culture of lilies; carbon dioxide assimilation of apple leaves; spray injury to apple leaves; relation of delayed storage and development of storage scald on Rhode Island Greening and Cortland apples; spacing and mulching of strawberries; breeding of blackberries; propagation of blueberries; and the effect of various factors such as fertilizer, moisture, photoperiods, etc., on the quality of celery as indicated by histological examination.

Inspection, certification, and transportation of nursery stock in Kentucky, with a brief report for the year ended June 30, 1938, W. A. PRICE and H. G. TILSON (*Kentucky Sta. Regulat. Ser. Bul.* 17 (1938), pp. 18).—This contains information as to regulatory activities and requirements.

The growth of plants in water and sand cultures, J. P. MARTIN and C. W. CARPENTER (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.], 43 (1939), No. 2, pp. 125-132, figs. 2*).—General information is presented on methods, equipment, materials, and economic considerations.

Vegetable variety and strain trials, F. K. CRANDALL (*Rhode Island Sta. Misc. Pub. 1 (1938), pp. [2]+11*).—The results of trials with tomatoes, cabbage, celery, lettuce, peppers, sweet corn, garden beans, late spinach, and beets are discussed.

Effect of temperature on the rate of deterioration of fresh vegetables, H. PLATENIUS. (N. Y. [Cornell] Expt. Sta.). (*Jour. Agr. Res. [U. S.], 59 (1939), No. 1, pp. 41-58, figs. 8*).—The rate of deterioration of seven kinds of fresh vegetables was determined for temperatures ranging from 35° to 83° F. When plotted against the temperature, the calculated temperature coefficients followed a logarithmic curve with a break between 50° and 65°. Q_{10} values expressing the rate of deterioration varied not only with different kinds of vegetables but also with different temperature ranges—the highest values always being found at relatively low temperatures. Temporary storage at 85° had no appreciable effect on the subsequent rate of break-down after transfer to higher temperatures. Different temperature coefficients and Q_{10} values were found to depend on whether the rate of deterioration was measured by visible break-down or by the rate at which sugar depletion occurs in these vegetables. Based on the rate of sugar losses, peas had a Q_{10} value of 27.5 at relatively low temperatures and 1.4 in the upper temperature range.

Fertilizer for cabbage, peas, methods of planting peas, J. A. CAMPBELL (*Miss. Farm Res. [Mississippi Sta.], 2 (1939), No. 7, p. 71*).—At the Truck Crops Substation, Crystal Springs, 1 year's trials indicated that 1,500 lb. of 4-8-4 fertilizer, sometimes supplemented by a side dressing of 200 lb. of nitrate of soda, was the maximum profitable application. Double-row pea plantings yielded about 50 percent more than single-row plantings with the same fertilizer.

Placement of fertilizer for spinach, kale, and collards, M. M. PARKER, R. C. OLIVER, G. A. CUMINGS, W. H. REDD, and L. G. SCHÖENLEBER. (Coop. U. S. D. A.). (*Virginia Truck Sta. Bul. 101 (1938), pp. 1595-1618, figs. 5*).—In studies extending over several years and conducted on three soil types—Sassafras sandy, Elkton silt, and Norfolk sandy loams—it was found that fertilizers placed in narrow bands on the sides of the seed row and below the level of the seed invigorated the germination of collards, kale, and spinach seed regardless of the soil moisture supply. Fertilizers placed in a narrow band directly below the seed were injurious, especially when the soil moisture was relatively low. Fertilizers broadcast several weeks in advance of or immediately prior to planting had very little effect on germination. Those mixed in the row just before planting kale and collards were toxic when moisture was inadequate. The amount of injury to seed germination with unfavorable placements was associated closely with the amount of rainfall directly preceding and following seeding. In the case of less fertile soils, fertilization following germination resulted in a period of comparatively slow growth. The largest yields of spinach and kale were obtained by side placement of fertilizer, while with collards slightly better results followed placement in a narrow band 3 in. directly below the seed.

Effect of temperature upon the rate of elongation of the stems of asparagus grown under field conditions, C. W. CUTPEPPER and H. H. MOON. (U. S. D. A.). (*Plant Physiol., 14 (1939), No. 2, pp. 255-270, figs. 5*).—For temperatures between 52.5° and 87.5° F. the relationship between the growth rate and the temperature was found represented by almost straight lines. The rate of total

elongation was approximately doubled with each increase of 18° over a limited temperature range. The rate of increase in height was slow at first, increased rapidly to about 65 cm. in height, and then slowly decreased as the stalks became taller. Growth responses were interpreted in terms of time required to reach different total heights. In a specific stalk, the zone of maximum growth (a short distance below the tip) was found to be a little more sensitive to changes in temperature than regions above or below this zone.

Effects of certain treatments on the carbohydrate reserves of asparagus crowns. L. E. SCOTT, J. H. MITCHELL, and R. A. MCGINTY (*South Carolina Sta. Bul.* 321 (1939), pp. [48], figs. 4).—Carefully selected crowns of Mary Washington asparagus planted at the Sandhill Substation in January 1930 and treated differentially with respect to fertilizer and cutting were sampled at 15-day intervals from October 3, 1932, to November 1933 and to a lesser extent in 1934 and 1935. The most striking feature was the very high percentage of total sugars present, largely nonreducing sugars in the fleshy roots. At the time of digging, moisture ran about 75 percent and was, in general, negatively correlated with the percentage of available food reserves. Starch was relatively low, seldom exceeding 3 or 4 percent of the dry weight. Total N was more variable, ranging from 0.7 to 2 percent of the dry weight. Hemicellulose was about 3 or 4 percent and crude fiber between 15 and 20 percent on a dry weight basis. The rhizome of the crown was apparently of comparatively little importance as a storehouse for reserve foods.

A comparison of the means of the samples during the 1-yr. period showed no significant differences in the percentages of carbohydrates in the crowns, as related to fertilizer treatments, but the roots from the high-N plots were significantly higher in total N. Extension of the harvest season approximately 2 weeks beyond the normal period greatly increased total yields without appreciable reduction in size of spear and without apparent permanent effect upon productive capacity. Fall harvesting, on the other hand, was definitely harmful, resulting in a lower carbohydrate reserve throughout the dormant period and extending through the period of top-growth renewal in the spring. Fall harvesting gave relatively low yields as compared with spring harvesting, due, in large part, to the small size of the spears. In general, the chemical studies suggested the need of maintaining vigorous top growth throughout the autumn to assure maximum production of spears the following spring.

Comparison of methods of applying fertilizer for cabbage. C. B. SAYRE (*Farm Res. [New York State Sta.],* 5 (1939), No. 3, pp. 9, 10).—Of different methods of applying fertilizer to cabbage grown in rotation with sweet corn and winter rye, the best results in terms of yield were secured when the fertilizer was applied, at the time of setting the plants, in bands 2.5 in. at each side of the row and from 3 to 4 in. below the surface. The application of 600 lb. per acre of 4-16-4 material produced profitable increments in yield each year. Rainfall during August and September was the most important single factor affecting the yield of cabbage.

Yellow sweet corn hybrids for New York. W. D. ENZIE (*New York State Sta. Bul.* 686 (1939), pp. 59, pls. 1).—A total of 48 varieties, all of which have been actually introduced to the seed trade, are discussed as to origin, parentage, time of maturity, yield, quality, detailed plant and ear characters, and value for canning and freezing preservation.

A trial of new varieties of hops for New York. J. D. HARLAN (*New York State Sta. Bul.* 687 (1939), pp. 8).—Of seven new varieties of hops tested by the station, Brewer Gold and Bullion were particularly promising, with the first-named variety outyielding any other by a wide margin. Both contained

greater percentages of soft resins, 22.78 percent in Brewer Gold and 26.72 percent in Bullion, than any of the standard American varieties.

Stimulation of germination of dormant lettuce seed by sulphur compounds. R. C. THOMPSON and W. F. KOSAR (U. S. D. A.). (*Plant Physiol.*, 14 (1939), No. 3, pp. 567-573, figs. 1).—Treatment of lettuce seed with dilute aqueous solutions of various chemicals showed that six solutions had marked stimulating effects. These chemicals were thiourea, allyl thiourea, thiosemicarbazide, ammonium thiocyanate, and potassium thiocyanate. After treatment, the seeds were placed in germination chambers in darkness at from 24° to 26° C. (75.2° to 78.8° F.) and germination recorded after 72 hr. All six materials contained S, but its presence was not the only condition necessary for growth. The results suggested that the presence of C, N, and S in some specific linkage is involved.

Variety and strain trials of Alaska and sweet types of peas for canning in Maryland. C. H. MAHONEY, W. A. FRAMER, H. A. HUNTER, and A. WHITE (*Maryland Sta. Bul.* 425 (1939), pp. 219-234, figs. 4).—From experiments extending over a period of 5 yr. it was evident that varieties and strains fluctuate from year to year and that testing over several years may be necessary for evaluation. However, in the Alaska group the inherent yielding capacity and quality of most of the strains were about equal. Superlaski, because of slightly greater vigor, slightly outyielded most of the Alaska strains. In a given variety, such as Alaska, there were noted certain differences in maturity dates and in size of the individual peas in the various strains.

Only two of the so-called sweet varieties—Wisconsin Early Sweet and Resistant Gem—were grown all of the 5 yr. Because of their more diverse origin, the sweet varieties differed more largely. Certain varieties proved adaptable to Maryland conditions, and a few produced more shelled peas per acre than did the Alaska type. The most outstanding sweet variety grown in 1937 and 1938 was the Dark Podded Thomas Laxton. This variety, Mardolah, and Pride can apparently be grown successfully on the Eastern Shore of Maryland. There was indicated the fact that the sweet varieties should be harvested at a relatively immature stage to secure satisfactory canning quality. Notes are presented on the number of seeds per pound, seeding rates, and stand of plants in one of the trials.

Canning peas in Wisconsin. E. L. DELWICHE, F. L. MUEBACH, W. B. SABLES, E. TACOG, J. C. WALKER, and H. F. WILSON (*Wisconsin Sta. Bul.* 444 (1939), pp. 24, figs. 7).—Herein is offered general information relating to the growing of canning peas compiled by a committee of station workers and based on the results of experiments in culture, plant breeding, and disease and insect control.

Relation between fruit size and food supply in the tomato. F. G. GUSTAFSON and H. B. HOGHTALING (*Plant Physiol.*, 14 (1939), No. 2, pp. 321-332, figs. 5).—The results showed that the size of fruits can be increased considerably by increasing the size of the vegetative structure before the time that the flowers are produced. By reducing the number of fruits to one cluster per plant, both the ovaries and mature fruits were greatly increased in size, but the fruits were not increased in proportion to the enlargement of the ovary. An increased leaf area per fruit resulted in larger fruits, but there was a definite limit to the size of the fruit, dependent on variety. There was a significant correlation between fruit size and the number of carpels.

Understocks for fruit trees. E. MAIER (*Die Unterleichen der Obstgehölze*. Berlin: Paul Parey, 1939, pp. XII+379, pls. 14, figs. [45]).—This handbook is designed to assist the nurseryman and fruit grower in the identification and culture of vegetatively increased rootstocks.

Growing fruit trees to withstand drought, W. P. BAIRD. (Coop. U. S. D. A.). (*North Dakota Sta. Biao. Bul.*, 1 (1939), No. 6, pp. 9, 10).—Based on studies at the Northern Great Plains Field Station, Mandan, N. Dak., general information is offered on location of sites, cultural practices use of shelterbelts, species of trees, and other factors that lead to successful fruit growing.

Some investigations on the assimilation of apple leaves, J. G. WAUGH. (Cornell Univ.). (*Plant Physiol.*, 14 (1939), No. 3, pp. 363-377, figs. 5).—Experiments with leaves of 1-year-old McIntosh, Delicious, and seedling apple trees growing in the greenhouse showed that the assimilation of CO₂ by the apple leaf subjected to uniform light intensity, restricted temperature variation, adequate water supply, and a slow, constant rate of air flow is very irregular from hour to hour on certain days and fairly constant on others. It appeared that internal factors must play a significant part in assimilation. There was evidently a transition range over which light intensity and rate of air flow are both limiting factors in assimilation. In general, under fairly uniform external conditions, leaf temperatures of about 38° C. (100.4° F.) apparently resulted in reduced assimilation, as compared with 30°. The critical temperature for assimilation by the apple leaf is believed to be about 35°.

Summer spray program for apples presents many problems, J. M. HAMILTON and S. W. HARMAN (*Farm Res. [New York State Sta.]*, 5 (1939), No. 3, pp. 1, 11, figs. 3).—The changing practices in spraying have brought about new problems, such as the removal of spray residues and the use of such materials as wettable sulfur which are less injurious to the tree. The use of newer materials is discussed, with suggestions as to their effectiveness.

Thinning peaches in western New York, H. B. TUKEY (*Farm Res. [New York State Sta.]*, 5 (1939), No. 3, pp. 1, 5, figs. 2).—Based on investigations conducted over a 3-yr. period in which peach fruits were thinned at different stages of development from full bloom to the final swell of the fruit as it reached maturity, the report is given that thinning at full bloom or when the fruits were 0.75 in. long resulted in an increase in the size of the pit and in the largest and best-colored peaches. All thinning tended to reduce total yield for the season, but early thinning had the least effect. Over the 3-yr. period, early thinning resulted in an increase in the number of blossoms in the light-crop year and in the size and the number of leaves per tree. As a result, there was a larger total yield for the 3 yr. as a whole, in comparison with no thinning or thinning at any of the later stages of fruit development. Thinning in the early stages is said to be more practical than that in the blossom stage.

Boysenberries: How good yields were made by station, T. E. ASHLEY (*Miss. Farm Res. [Mississippi Sta.]*, 2 (1939), No. 7, p. 2, fig. 1).—Of four methods of training compared in a planting established in February 1938, that system which provided two parallel wires 18 in. apart and the lower of which was 24 in. above the soil gave the best results, with 19 plants averaging 10.87 qt. of berries per plant. Suggestions as to culture, fertilizer, picking, and the uses of the fruit are included.

The effect of lime on the low-bush blueberry, F. B. CHANDLER. (Maine Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), p. 477).—Lime at the rate of 1, 2, 3, or 6 tons per acre for 1, 2, and 3 yr. failed to show any detrimental effects, even where a total of 18 tons was applied. In fact, most of the limed plants showed notable increase in yield. A study of the pH of the soil from the 18-ton plots showed the top inch to be slightly alkaline. A composite sample of the upper 6 in. of soil in the 18-ton plot showed a pH change from about 5 to 6.6.

Results of 47 years of breeding grapes at Geneva, L. M. VAN ALSTYNE (*Farm Res. [New York State Sta.], 5 (1939), No. 3, p. 3, 4, fig. 1*).—Emphasis is placed, in this résumé, on the use of *Vitis vinifera* as a parent to secure better quality. Over 25,000 seedlings were produced, and of these the majority resulted from controlled crosses with both parents known. Of these seedlings, about 900 have been selected for further trial, and a total of 25 have been given names. Of the 22 varieties now recommended for planting in New York State, 9 were originated at Geneva.

Influence of certain cultural systems upon root distribution of black raspberries, L. HAVIS. (Ohio Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc., 35 (1938), pp. 478-480*).—Part of a plantation established in the spring of 1931 was mulched with straw, and part was clean cultivated. Observations in trenches dug in 1938 in two directions beneath each type of culture showed no significant differences in the depth of rooting in both areas, with roots found to a depth of from 4 to 5 ft. in each case. The lateral distribution of roots was also similar. There was some tendency for fibrous roots to develop just below the mulch and in the partly decomposed material, but to a lesser degree than would occur in apple orchards. The total number of roots was larger under cultivation than under mulch. There was a decreasing gradient in the number of roots of all sizes from the surface foot downward.

Root and crown development of strawberries, C. W. VAN HORN, A. L. SCFRADER, and I. C. HATT. (Md. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc., 35 (1938), pp. 461-465, fig. 1*).—Observations on the runners produced by Blakemore plants set in March 1937 in the sandy loam near Salisbury, Md., showed well-defined responses to spacing and fertilizer treatments. Plants from thinned rows developed larger roots and crowns as compared with those from matted rows. All early-formed runners developed dry weight of roots at a rapid linear rate during the growing season, but the plants in matted rows slowed down much earlier than did the spaced plants. Fertilizers applied in mid-August or mid-September were effective in increasing the dry-matter content of the roots. The longer continuance of growth of plants in thinned rows, as well as response to fall fertilizers, is believed to contribute to their better fruiting performance.

Distribution of soluble solids in citrus juices, E. T. BARTHOLOMEW and W. B. SINCLAIR. (Calif. Citrus Expt. Sta.). (*Calif. Citrog., 24 (1939), No. 10, pp. 352, 362, 363, 382, 383, 384, fig. 1*).—Separate determinations of the total soluble solids in the stem and styler halves of individual segments of immature Valencia oranges showed, in many cases, that these solids were more abundant in the stem ends. As maturity advanced, all segments had more total soluble solids in the styler ends. The same phenomenon was noted in Washington and Thompson Navels and in grapefruit and may help to explain localization of freezing injury where, in certain cases, a single segment showed freezing injury. In analyzing some 1,500 segments there were found cases where a single segment contained as much as 3.5 percent less total soluble solids than certain of its companions. In fruits harvested from the outer portion of the tree it was noted that, irrespective of the position on the tree, the north segments were almost always higher in total soluble solids. The results were not consistent with the interior fruits. Variation was observed in the color of the juice expressed from the styler and stem halves of individual segments. Observations on Navel oranges collected between December 30 and January 4 showed that the percentage of titratable acid (expressed as citric acid) was in most cases greater in fruits taken from the north side of trees. In similar tests with Valencias harvested in March and April, the soluble solids were highest in the fruits from the south side. In all but one orchard the acid was higher in the fruit taken from the south side.

In Navel fruits of various sizes taken from the packing house in early April there was a gradual increase in concentration of soluble solids as size decreased. The same trend was noted in the case of Valencia^c collected in May. The results suggest the need of greater care in selecting samples for analysis.

Processing of the macadamia. R. H. MOLTZAT and J. C. RHPERTON. (Coop. U. S. D. A.). (*Hawaii Sta. Bul.* 83 (1939), pp. 31, figs. 13).—Herein is presented information regarding the drying of nuts, methods of cracking, grading, cooking, storage, etc. In drying tests in which kernels were placed in a series of jars containing sulfuric acid and water mixtures it was found that air drying was not effective in reducing the moisture content to the most desirable percentage for cracking (3.5 percent) when relative humidities were above 60 percent. Nuts placed in a wire-bottomed tray and exposed to the direct rays of the sun were dried to a kernel moisture content of 2.8 percent in 1 week. Kernels dried in the sun or with artificial heat required, for some unexplained reason, a longer cooking time to reach a certain degree of brownness than did air-dried nuts. Cracking, cooking, and taste tests of artificially dried nuts indicated that the final product was of excellent quality even when a temperature as high as 172° F. was employed. A total of five lots, (1) unshelled air-dried nuts in burlap sacks, (2) air-dried kernels in open containers, (3) air-dried kernels in sealed containers, (4) dehydrated nuts in sealed containers, and (5) oven-roasted kernels in sealed containers, were kept at various temperatures. The results indicated that if macadamia nuts were to be kept for more than 3 mo. they should be stored as dehydrated kernels in cold storage and in sealed containers. Cooked kernels deteriorated more rapidly in storage than did dehydrated.

Problems in the storage of cut carnations. M. S. NEFF. (Iowa State Col.). (*Plant Physiol.*, 14 (1939), No. 2, pp. 271-284, figs. 10).—Cut blooms stored at 33° F. kept better than those at 40°. Flowers stored without being placed in water were comparable in keeping quality and carbohydrate reserves with fresh blooms. Storage with stems in water was not found desirable because of poorer keeping and loss of carbohydrates. Such blooms lost weight when moved to room temperatures. Good keeping was favored by high humidity. Carnations wilted prior to storing "dry pack" kept better than when stored in a turgid condition. A reduction in turgor pressure rather clearly reduced the rate of maturity.

FORESTRY

Influence of moisture supply on drought resistance of conifers. H. L. SHIRLEY and L. J. MULL. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 59 (1939), No. 1, pp. 1-21, figs. 3).—The relative drought resistance of various lots of conifer seedlings was determined by the Lake States Forest Experiment Station by exposing them to artificial drought produced in a new "drought machine" consisting of an illuminated plant chamber provided with temperature and humidity control in which potted plants resting on a revolving table were exposed to constant wind velocity. The length of time conifer seedlings, potted in sand at 5-percent moisture content, remained alive in the machine was used as a criterion of drought resistance. This was found to be substantially in agreement with the field survival during periods of natural drought of corresponding lots of seedlings. Increased resistance to drought was induced in *Pinus strobus*, *P. resinosa*, and *P. banksiana* seedlings by subjecting them, during the growing period, to moderate soil drought. Such treatment tended to increase root development and restrict top development, but improved resistance did not depend solely on size of root, size of top, or ratio of root to top. Resistance built up in 2-year-old *P. resinosa* by controlled watering was found to persist to a significant degree during the

following season. Severe exposures to soil dryness temporarily weakened the plants, and unless followed by an ample period of recovery rendered them more susceptible to drought. The possibility of using controlled watering as an expedient for improving drought resistance of pine seedlings was demonstrated to be practical by applying this method in a large forest nursery.

The influence of soil nutrients on drought resistance of two-year-old red pine, H. L. SHIRLEY and L. J. MEULL (U. S. D. A.). (*Amer. Jour. Bot.*, 26 (1939), No. 6, pp. 355-360).—Observations on 1-year-old red pine (*Pinus resinosa*) seedlings, grown during their second season in pots or nursery beds supplied with varying amounts of N, phosphate, and water and then subjected to drought-resistance tests under controlled conditions, showed that N applications had markedly reduced resistance. As to water, nursery-grown plants grown without N and watered daily were less resistant than those watered at 3-day intervals. With N, the water effect was obscured because heavy watering leached the N. With no N supplied, an increase in phosphate increased drought resistance. With N present, the beneficial effects of the phosphate persisted, but the optimum combination of N and phosphate was not determined.

Transpiration and physico-chemical properties of leaves as related to drought resistance in loblolly pine and shortleaf pine, C. S. SCHOPMEYER (U. S. D. A.). (*Plant Physiol.*, 14 (1939), No. 3, pp. 447-462, figs. 2).—Placed in the greenhouse in December 1935, vigorous 1-year-old loblolly pine and shortleaf pine seedlings in 2-gal. cans containing Congaree silt loam were submitted, after a period of establishment, to three conditions of soil moisture. (1) adequate for optimum growth, (2) unwatered, and (3) soil allowed to dry to the wilting coefficient then restored to the optimum. Of the two species, the shortleaf pine was known to be more tolerant to dry conditions. With optimum water supply, 30 percent, shortleaf pine had a higher transpiration rate, more total water, higher osmotic pressure, and a greater solute concentration than loblolly pine. Bound water was not significantly different in the two species. At the wilting coefficient, shortleaf pine had a higher transpiration rate, more total water, and lower osmotic pressure than loblolly pine. Solute concentration and bound water were practically the same in both species. Water restoration after drying resulted in more total water, greater osmotic pressure, and higher solute concentration in the shortleaf pine. Bound water decreased in both species when the water supply was restored. Shortleaf pine absorbed more water from the soil and maintained a higher total water content in its leaves than did loblolly, even when soil moisture was limited.

Fire Control Notes, [July 1939] (U. S. Dept. Agr., Forest Serv., *Fire Control Notes*, 3 (1939), No. 3, pp. II-38, figs. 8).—Brief articles are presented relating to technic, equipment, experiences, etc.

DISEASES OF PLANTS

The Plant Disease Reporter, July 31 and August 15, 1939 (U. S. Dept. Agr., Bur. Plant Indus., *Plant Disease Rptr.*, 23 (1939), Nov. 14, pp. 225-252; 15, pp. 253-265, fig. 1).—The following items of interest are included:

No. 14.—A new potato disease resembling "bluistem" and "purple-top" in New York, by P. Decker; late blight and tipburn on potatoes in New York; potato diseases and onion diseases in Massachusetts, by O. C. Boyd; notes on onion diseases in New York, by A. G. Newhall; some reports on diseases of cucurbits, including cucurbit mosaic and bitter flavor, diseases of cucurbits in New York, and severe occurrence of downy mildew in south Georgia; tobacco diseases and the general plant disease situation in Massachusetts, including fruits, vegetables,

and ornamentals, by O. C. Boyd; incidence of fruit diseases (parasitic, nonparasitic, virus, and miscellaneous) in Idaho in 1937 and 1938, by E. C. Blodgett; some important diseases of cereals, corn, sorghum, and cowpeas in Oklahoma, by K. S. Chester; rice straw-ticks as a source of infection with the black kernel disease (*Curculio leucotus*), by A. L. Martin; and brief notes on plant diseases (strawberry red stele appears in Connecticut, perithecia of *Venturia inaequalis* still active in New York, *Fusicladium* wilt of peach trees in New York, X-disease on wild cherry in Massachusetts—a correction, bacterial stalk rot of corn found in Kentucky, and bacterial wilt of sweet corn in New York).

No. 15.—Red suture disease of peach reported from Maryland, by E. A. Walker; peach leaf curl incidence in Illinois in 1939, by G. H. Boewe; some reports on apple rust on fruit in Illinois, unusual occurrences of cedar rusts in New York, apple blotch in Illinois, peach viroses in Massachusetts, and red stele of strawberry reported from Wisconsin; spotted wilt of tomatoes in Missouri, by J. T. Middleton and C. M. Tucker; bacterial ring rot of potato in New York, by H. S. Cunningham; reports on bacterial canker of tomatoes and fertilizer injury in Massachusetts, cabbage yellows in New York, *Fusarium* wilt of spinach destructive on Long Island, *Fusarium* wilt of potatoes in Massachusetts, halo blight and *Alternaria* spot of lima beans on Long Island, salt injury to celery and other crops in Massachusetts, and celery diseases in New York; and poor growth of corn following lespedeza, by S. Diachun and W. D. Valleau.

[Phytopathological studies by the New Mexico Station]. (Partly coop. U. S. D. A.). (*New Mexico Sta. Rpt. 1938*, pp. 20, 21, 41, 42).—Brief reports of progress are included on curly top of sugar beets, treatments for chlorosis of various plant species, and *Ozonium* root rot.

Proceedings of the thirty-seventh annual meeting of the North Carolina Academy of Science (*Jour. Elisha Mitchell Sci. Soc.*, 54 (1938), No. 2, pp. 189, 190, 191, 192, 193).—The following abstracts of papers are of interest to phytopathology: Host Range Studies With *Bacterium solanacearum*, by T. E. Smith; Some Parasitic Fungi Harbored by Peanut Seed Stock, by M. M. Evans and R. F. Poole; The Role of Magnesium in a Chlorosis of Peach, by J. C. Hackney; and Notes on a Bacterial Disease of the Tubers of the Jerusalem Artichoke, *Helianthus tuberosus*, by L. Shanor.

[Plant disease studies by the Rhode Island Station] (*Rhode Island Sta. Rpt. [1938]*, pp. 23, 36, 37, 40-43, 44, 45-49).—Brief reports are included on the status of work on diseases of fine turf and turf grasses and their control (snow mold, leaf spot, brown patch, and dollar spot); spray injury on tomatoes; partial soil sterilization with chloropicrin for various crop plants and for weed control; field tomato disease control with fungicides; chemical control of nematodes in tomato greenhouses; chloropicrin treatment of seedbed soil; buckwheat growth retardation by chloropicrin in culture solutions; response of eggplants to field soil fumigation with chloropicrin; onion varietal resistance to downy mildew; potato spray tests for disease and insect control; disease and pest control in *Lilium formosanum*; seasonal development of apple scab; and a serious maple blight associated with a pythiaceus fungus.

Seventeenth annual report of the Canadian Plant Disease Survey, 1937, I. L. CONNERS (*Canada Dept. Agr., Sci. Serv., Plant Disease Survey Ann. Rpt.*, 17 (1937), pp. XI+87).—Following the general sections on new or noteworthy diseases, phenological data, and weather and its influence on plant diseases, specific diseases are taken up under cereal crops, forage and fiber crops, vegetable and field crops, fruit crops, forest and shade trees, and ornamental plants. A host index is provided.

Eighteenth annual report of the Canadian Plant Disease Survey, 1938, I. L. CONNERS (*Canada Dept. Agr., Sci. Serv., Plant Disease Survey Ann. Rpt., 18 (1938), pp. XII+112*).—Following general sections on new or noteworthy diseases, phenological data, and weather and its influence on plant diseases, specific diseases are taken up under cereal crops, forage and fiber crops, vegetable and field crops, fruit crops, forest and shade trees, and ornamental plants. A host index is provided.

A new fungus with anteriorly uniloculate zoospores: *Hyphochytrium catenoides*, J. S. KARLING (*Amer. Jour. Bot., 26 (1939), No. 7, pp. 512-513, figs. 18*).—*H. catenoides* n. sp. (described and illustrated) was found as a weak parasite and saprophyte in trichomes and parenchyma cells of corn and in cooked internodes of *Chara* and *Nitella*.

On the systematic position and generic names of the gram negative bacterial plant pathogens, W. J. DOWSON (*Zentbl. Bakt. [etc.], 2. Abt., 100 (1939), No. 9-13, pp. 177-193*).—Examination of the cultural and biochemical characters as exhibited by a large number of the gram-negative bacterial plant pathogens on a variety of media led the author to conclude that the plant pathogens could be arranged in three groups, one like *Bacterium coli*, a second like *Pseudomonas fluorescens*, and a third unlike either for which the name *Xanthomonas* n. g. is proposed. The salient characters of the three genera and lists of the species included in them are given in tabular form, the species mentioned being those studied by the author together with other gram-negative plant pathogens that have been fully described elsewhere. There is a copious bibliography.

Osmotic and permeability relations in the nutrition of fungus parasites, F. S. THATCHER (*Amer. Jour. Bot., 26 (1939), No. 6, pp. 449-458, figs. 11*).—The fungi used in this study were *Cromyces fabae* on pea, *T. caryophyllinus* on *Dianthus caryophyllus*, and *Botrytis cinerea* and *Sclerotinia sclerotiorum* from decaying celery petioles. Osmotic values were obtained for germ tubes and haustoria of the rusts, for hyphae of *Botrytis* and *Sclerotinia*, and for diseased and healthy tissues of the hosts—in all cases greatest for the fungus. Permeability measurements in diseased and healthy tissues of rusted plants indicated that rust increases the permeability of the host plasma membranes. Absolute permeability values for water, urea, and dextrose were calculated by Scarth's simplified formulas (*E. S. R., 81, p. 346*). This increase was apparently due to some secretion from the fungus as indicated by tests with juice extracts of tissues containing its hyphae. Increased permeability was also apparent in celery tissues some distance from the cells killed by the fungi. A theory based on the results reported is elaborated to explain the mechanism of transfer of food and water from host cells to parasite as manifest in these rusts, permitting an explanation of how cells are able to remain alive even though continually taxed by the parasites. Light is also thrown on other hitherto unexplained phenomena.

Danger in seed importation, H. P. BARRS, (T. S. D. A.). (*Phytopathology, 28 (1938), No. 12, p. 939*).—The author lays stress on the general danger of introducing plant diseases into the United States through seed importations, noting especially a new cotton anthracnose (*Colletotrichum* sp.) recently reported as occurring in Manchukuo.

Snow-mould of turf in Alberta, W. C. BROADFOOT (*Jour. Bd. Greenkeeping Res. [England], 5 (1938), No. 18, pp. 182, 183*).—The conditions favorable and unfavorable for turf in Alberta are discussed, and it is stated that when the snow cover melts slowly, too early, or too often in spring or early winter the growth of parasitic low-temperature fungi, such as the *Fusarium nivale* causing

snow mold, is favored. *Fusarium* spp., a basidiomycete, and *Rhizoctonia* sp. were isolated from diseased crowns and roots of grasses in golf greens, and the first two proved fairly pathogenic and the last only slightly so. Trials of calomel and mercuric chloride for snow mold led to the recommendation of equal parts of these fungicides to be applied in the fall at the rate of 4 oz. per 1,000 sq. ft.

Boron deficiency symptoms in the genus Brassica, F. B. CHANDLER. (Maine Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), p. 549).—An abstract.

Bacterial wilt and soft rot of the potato in Maine, R. BONDE (Maine Sta. Bul. 396 (1939), pp. 675-694, figs. 4).—The bacterial wilt and soft rot (probably due to *Phytophthora scabedonia*) recently described from Maine (El. S. R., 77, p. 349) is reported as becoming of major importance in some parts of the State, losses being estimated at \$32,000 in 1937 and nearly \$80,000 in 1938. The disease is apparently not soil-borne in Maine, but is perpetuated in the seed tubers. Increase in the field is often very rapid and seed stocks with only a trace may develop a high percentage the following year. Experiments have demonstrated dissemination in the field, but the spread is not extensive beyond the first row, though more down a hillside slope. Contamination of freshly cut tubers from affected ones will spread the disease. Seed tubers bruised and contaminated before winter storage developed the disease in 7.6 percent of the progeny, while similar tests of unbruised tubers gave only 1 percent. A knife contaminated from an infected tuber was found capable of transmission to the fifth successive seed piece cut thereafter. The amount of such infection was reduced by drying the seed quickly after cutting. The disease was controlled neither by careful examination during cutting nor by roguing and seed plat methods, but the amount was reduced by planting whole tubers. The only known practical method of control is by exclusive use of healthy seed. Planting of seed plots in proximity to affected potato fields should be avoided.

Virus diseases of potatoes [trans. title], L. GARBOWSKI (*Bibliot. Puławska, Państ. Inst. Nauk. Gosp. Wielek. Puławach*, No. 18 (1938), pp. [4]+98, pls. 6).—A monograph of the subject (97 references).

Pythium root rot of sugar cane in Louisiana, C. W. CARPENTER (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.]*, 43 (1939), No. 2, pp. 115-118).—A review of salient points regarding the *P. arrhenomanes* root rot, stressing its importance to sugarcane production in Hawaii and quoting the summary of studies by Rands and Dopp (El. S. R., 80, p. 500).

A description of certain nutrient deficiency symptoms of the Porto Rico sweetpotato, J. B. EDMOND and H. J. SEFICK. (S. C. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), pp. 544-549, fig. 1).—Experiments were set up to study the relative effects of a complete nutrient supply as compared with various deficiencies. As to the tops of the plants, a lack of N, P, or K had a much greater influence in reducing growth than a lack of Mg or Ca. With respect to the fleshy roots, plants lacking Ca produced a small number of moderately large roots, and those without Mg the reverse. Plants with complete nutrient or minus P produced a small number of moderately small roots, those minus N a large number of small roots, and those minus K a small number of exceedingly small roots, the last effect, particularly striking, indicating that a continuous supply of K is not only necessary for developing a large number of roots but also for developing large sized ones. As to color of skin and flesh, three groups were evident—the minus N plants produced roots with dark-pink skin and pink flesh, the complete nutrient, and the no Ca or no Mg ones produced roots with light-pink skin and flesh, and the no P or no K plants pro-

duced roots with creamy white skin and flesh. It seems evident that the proportion of N to other nutrients and particularly to K has an important bearing on the color of the skin and flesh.

Oat nematodes on winter wheat, L. J. CHAPMAN (*Sci. Agr.*, 18 (1938), No. 9, pp. 527, 528, pl. 1).—This reports a serious outbreak of injury by *Heterodera schachtii* on winter wheat sown in infested soil.

Diseases of vegetable crops, J. C. WALKER (*Ann Arbor, Mich.: Edwards Bros.*, 1939, pp. [3]+67).—This is the first revision of the work previously noted (E. S. R., 77, p. 801).

Progress in breeding cucumbers resistant to scab (*Cladosporium cucumerinum*), R. M. BAILEY. (Maine Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), pp. 645, 646).—Continuing the work earlier noted (E. S. R., 74, p. 340), this is a brief progress report.

Calcium cyanamide as a crown treatment, G. R. HOERNER (*Pacific Hop Grower*, 5 (1938), No. 11, p. 7).—From 52 replies to a questionnaire sent to hop growers in British Columbia, California, and Oregon, it appeared that in general when calcium cyanamide was used as a crown treatment for downy mildew control according to directions (2 oz. before hoeing applied to the soil surface over the crown in a circle approximately 2 ft. in diameter, avoiding replants) little injury resulted, the development of basal spikes was suppressed, and increases in yields were secured.

A trace element deficiency on the tomato, J. B. HESTER (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), pp. 744-746, fig. 1).—The symptoms described were apparently entirely different from others previously reported. For the most part they were induced in water or sand culture, boron alone or in combination apparently being the only corrective treatment. It is deemed possible that only a partial deficiency existed, which may have been associated with other elements absorbed by the plants from the soil which had not been present in former studies. While only one or two cases were noted in the field during the past season, it may be more common than is expected. It is emphasized that extreme care should be exercised in applying trace elements to tomatoes.

Control of tomato leaf mold in greenhouses, E. F. GIBBA (*Massachusetts Sta. Bul.* 361 (1939), pp. 36, figs. 7).—This compendium (56 references) presents descriptions of various practices contributing to the control of *Cladosporium fulvum* leafmold, a serious foliage disease of greenhouse tomatoes, and includes the results of work by the station. Successful control is said to involve cultural practices, greenhouse management, location and design, and the use of chemicals for disinfecting the greenhouse interior and protecting the plants from infection. These factors are discussed in detail.

A recurrence of broomrape, *Orobancha ramosa* L., on tomato plants in California, G. L. STOUT (*Calif. Dept. Agr. Bul.*, 27 (1938), No. 2, pp. 166-171, figs. 4).—The author reports an outbreak of parasitism on tomato in 1929, and a recurrence on this host in 1934 after the field had been in alfalfa for at least three of the four intervening years. Again other crops were grown on the infested soil, but in 1937 the pest reappeared when tomatoes were planted. It seems apparent, in this case, that the tomato is a highly favored host.

The work of others is briefly reviewed, including presentation of a list of 29 hosts said to be liable to attack.

The influence of bordeaux spray on the growth and yield of tomato plants, V. G. SHUTAK and E. P. CHRISTOPHER. (R. I. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), pp. 747-749).—The data presented "seem to support the claim that bordeaux retards ripening to some extent but may control disease sufficiently well to increase the total yield during some seasons. It is also defi-

nately indicated that high-lime bordeaux should be avoided and that high-copper bordeaux may be safely and satisfactorily used. Our observations indicate that the injury from lime must be considered along with possible copper injury."

The influence of sulphur dust on the rate of photosynthesis of an entire apple tree, A. J. HLINICKI. (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), pp. 202-204) —Using the methods and equipment previously described (*E. S. R.*, 77, p. 483), this study indicated that finely divided sulfur dust, as compared to lime-sulfur solution, has relatively little influence on the photosynthetic rate of the leaves of an entire Baldwin apple tree. Even though sulfur dust may cause some leaf scorch in extremely hot weather, this injury is usually much less than where lime-sulfur has been used.

The effect of dilute liquid lime-sulphur sprays on the photosynthesis of apple leaves, H. W. BRODY and N. F. CHILDERS. (Ohio Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), pp. 205-209, figs. 4).—It is deemed evident from this brief report that dilute lime-sulfur sprays may cause marked reductions in the apparent rate of photosynthesis of Stayman Winesap apples for 3-5 days after application, even though no visible burning occurs. It also seems evident that when the maximum temperature reaches 90°-100° F. a significant reduction in assimilation usually occurs regardless of the spray concentration in contact with the leaf tissues. In these experiments the photosynthetic rate (three exceptions) of sprayed leaves showed a reduction on the first day after treatment. Otherwise the reduction in assimilation occurred not later than the second day following application.

The effect of copper compounds applied to spur units during bloom upon the set of apple fruits, L. H. MACDANIELS and E. M. HILDEBRAND. (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), pp. 230-233).—In spite of the known toxicity of copper compounds to pollen germination, their use has failed to give the expected results in reducing the fruit set, the explanation probably being related to the location of the pollen grains on the papillose stigma with respect to the grains of copper-lime dust and the failure of the spray to cover the stigmatic surface completely. This study emphasizes the very complex nature of the setting process and the many factors involved. From the standpoint of practice the results presented give further weight to the statement that these copper compounds (copper-lime dust and bordeaux mixture) may be applied to blooming apple trees without seriously reducing the fruit set.

An apple leafspot associated with *Fabraea maculata*, M. C. GOLDSWORTHY and M. A. SMITH. (U. S. D. A.). (*Phytopathology*, 28 (1938), No. 12, p. 938).—In addition to parasitizing the leaves of pear seedlings, this fungus was observed to cause similar leaf spots on French crab and McIntosh apple scions grafted on various rootstocks.

A case of rosette on apple in Virginia, H. W. RIDGWAY (*Amer. Soc. Hort. Sci. Proc.*, 34 (1937), pp. 227-229, fig. 1).—This is a description of a case responding to zinc therapy, the preliminary data being presented since zinc deficiency is said not to have been previously reported from apple districts east of the Rocky Mountains.

Some associated factors in the development of watercore, C. P. HANLEY. (U. S. D. A.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), pp. 435-439, fig. 1).—In the initiation of water core, aside from the fundamental influence of high temperature, leaf area appeared to play a very important role, since in no case was water core found in fruits grown with 10 leaves per apple although their exposure to the sun was at least as great as those with a larger number of leaves, where it occurred in greater or less amounts. Next in importance was nitrogen, the highest percentage of water core for a given leaf area being

found in the nitrated plats. The influence of moisture was not as clear, though for the most part more affected fruits were present in the "dry" plats. The results here reported from Wenatchee, Wash., are believed to offer evidence that factors intimately connected with carbohydrate metabolism in the leaf are predisposing to water core.

Physiological studies in lime-induced chlorosis, Y. MEAD (*Egypt. Min. Agr., Tech. and Sci. Serv. Bul.* 211 (1939), pp. [31]+56, pls. 7, figs. 3).—A case of lime-induced chlorosis in pear trees, occurring on soils containing ± 15 –40 percent CaCO_3 , was studied in detail and is described. Less Fe was found in the ash of stems and leaves of affected trees than in normal green trees on noncalcareous soils, and the chlorotic leaves showed a higher content of Ca and Mg. The susceptibility of pear, apple, white lupine, and rice to chlorosis on calcareous soils was found to be related to a relatively slow rate of CO_2 production from their root systems, while sunflower, buckwheat, cotton, corn, and barley, which did not develop the chlorosis on such soils, gave a much higher rate of CO_2 from their roots than the first group. The importance of CO_2 in increasing the solubility of Fe in lime soils was shown by quantitative analysis, and it proved possible to prevent chlorosis in lupines growing in suspensions of calcareous soils by applying CO_2 . The part played by CO_2 given off by roots in increasing Fe availability in calcareous soils is suggested as due (1) to lowering the pH of the soil solution around the root hairs and rootlets, and (2) to acting as a solvent for FeCO_3 which might form in the lime soil from reduction of ferric oxides in the presence of organic matter and excessive moisture.

Variation in resistance to brown rot in apricot varieties and seedling progenies, C. O. HESSE (U. S. D. A.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), pp. 266–268, fig. 1).—The springs of 1935 and 1938 having been especially favorable to brown rot development in central California at the time apricots were in bloom, the trees in the variety block at Davis were rated as to relative resistance. Similar ratings were also made in a large seedling block. The readings for the 2 yr. in the variety block checked very closely. Though not conclusive, the results were deemed of value in indicating the relative resistance to brown rot of the different varieties and their general behavior in transmitting resistance.

Bacterial canker of sweet cherry trees, D. T. PALMITER (*Farm Res. [New York State Sta.]*, 5 (1939). No. 3, p. 6, figs. 2).—This disease was first noted during the spring and summer of 1938 in the Hudson Valley, but has since been reported in western New York and Pennsylvania. It was found to be similar to if not identical with the serious disease of cherry known on the Pacific coast and in Europe for many years. Besides the trunk and limb cankers, blossom blight and leaf spot phases may appear in moist weather and terminal shoots may become infected and die back to older wood. The cankers are most active while the trees are dormant, the disease being favored by mild winters and rainy weather. Windsor appeared to be the most resistant variety in 1938, and Giant the most susceptible. With present knowledge, removal of diseased branches during the growing season and prevention of early defoliation to shorten the dormant period are the only control measures recommended.

The effect of potash on leaf-curl of sour cherry, L. R. LANGORD (Univ. Wis.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), pp. 261, 262, fig. 1).—With respect to the leaf curl of cherry previously reported (E. S. R., 75, p. 650), subsequent trials have shown that affected trees fertilized with potash had less leaf curl and greater shoot growth than comparable trees without it.

Symptoms of malnutrition in the peach resulting from various combinations of nutrient deficiencies, O. W. DAVIDSON (N. J. Expt. Stas.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), pp. 87, 88).—An abstract.

First progress report on prune drouth spot, A. B. BURELL and R. M. HEINICKE. (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), pp. 275-278, fig. 1).—As a phase in the study of the so-called drought spot of prune, mineral nutrient plats were laid out in three western New York State prune orchards. The materials applied were borax, $(\text{NH}_4)_2\text{SO}_4$, K_2SO_4 and superphosphate, CuSO_4 , ZnSO_4 , MnSO_4 , and FeSO_4 . In 1938 only one of these orchards had an appreciable amount of drought spot, and the only plat with consistently less of it than adjacent controls was the one receiving K_2SO_4 and superphosphate. Whether this difference was due to the treatment or to accident further tests alone will show.

Prevalence of certain diseases affecting the foliage in some strawberry progenies, J. H. CLARK. (N. J. Expt. Stas.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), pp. 455-460).—Certain data secured in connection with the strawberry breeding projects are here summarized with respect to leaf scorch (*Diplocarpon earliana*), powdery mildew (*Sphaerotheca humuli*), and June yellows.

Deficiency symptom patterns in citrus, O. C. BAXAN (*Citrus Indus.*, 19 (1938), No. 3, pp. 11-15, figs. 2).—Following a brief general discussion the author presents synopses of deficiency symptoms for Mg, Zn, B, N, Fe, K, Ca, Mn, P, and Cu—all but the last two being also illustrated.

Some symptoms of citrus malnutrition in Florida, A. F. CAMP and B. R. FUDGE (*Florida Sta. Bul.* 335 (1939), pp. 55, pls. 8, figs. 11).—Research revealing the specific relationship between nutritional requirements and certain symptoms exhibited by the citrus tree has furnished the basis for using these symptom expressions on leaves, twigs, and fruits as guides to fertilization. In this bulletin—intended as a reference work—the authors endeavor to bring together the gist of the pertinent information now available (196 references) on Cu, Zn, Mn, Mg, N, Fe, and B deficiency and on B toxicity in relation to citrus, with illustrations in color of the more common symptoms of these types of malnutrition as observed in Florida. A number of other symptom complexes apparently due to malnutrition are briefly noted.

Manganese deficiency in citrus in Florida, A. F. CAMP and M. PEECH. (Fla. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), pp. 81-85, fig. 1).—"Manganese deficiency symptoms on citrus as they occur in the field in Florida were found to resemble the symptoms of zinc deficiency as to leaf pattern but much less pronounced. It can be corrected both by applications of manganese salts to the soil and to the leaves. Its occurrence on both acid and alkaline soils is discussed in relation to the soil analysis."

A new disease of papaya in Hawaii, G. K. PARRIS. (Hawaii Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), pp. 263-265, figs. 3).—This disease was first noted in 1937, with losses estimated at 6-30 percent. Investigations, begun in 1938 and here reported in a preliminary way, appear to indicate its virus nature. Affected plants are badly stunted, the foliage is characteristically yellowed, and the individual leaves are crinkled and at the same time bent downwards and inwards. The symptoms are described in detail and illustrated.

The effect of root-knot upon the subsequent growth of tung-oil (*Aleurites fordii*) seedlings, R. D. DICKEY and H. MOWBY. (Univ. Fla.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), pp. 389-392, figs. 2).—"It is clearly indicated that tung-oil seedlings are highly susceptible to attack by the root knot nematode their first growing year in the nursery, whereas these same seedlings, when planted in the field at 1 yr. of age or older, are apparently quite resistant if not immune. Furthermore, severely affected seedlings when planted in the field show no further infestation and eventually grow out of any evidence of the previous infestation, as far as the root system is concerned. The effect of the

nematode root knot attack has been such as to weaken the vigor of the seedling trees, and subsequent exposure to low temperatures resulted eventually in the death of 8 of the 19 trees. Also, nursery stock which has become stunted from any cause will ordinarily fail to grow into vigorous field trees and for that reason should not be planted."

Symptoms of boron deficiency in the rose. O. W. DAVIDSON and H. M. BIEKART. (N. J. Expt. Stas.). (*Amer. Soc. Hort. Sci. Proc.*, 35 (1938), pp. 841-844, figs. 2).—In September 1938, Briarcliff roses in a demonstration test developed a type of injury believed not to have been described before and diagnosed as due to boron deficiency. The symptoms on the leaves, preflowering stems, and flowers are described in detail, with notes on a "meager study" of the effects on composition of the plants.

Downy mildew of the rose in British Columbia. W. JONES (*Sci. Agr.*, 18 (1938), No. 10, pp. 627, 628, fig. 1).—This note reports considerable injury by *Peronospora sparsa* to the varieties Portadown and Lord Lonsdale, and slight infection on the varieties Mrs. Gladys Peach, Mrs. H. Morse, Mrs. Laxton, Lal, Crimson Glory, Trigo, and Mrs. C. Lamplough. The leaves, stems, and flowers were affected.

Control of snapdragon rust (*Puccinia antirrhini* D. & W.). W. R. FOSTER (*Sci. Agr.*, 18 (1938), No. 9, pp. 524-526, pl. 1).—Copper sprays proved more effective than sulfur for control in the British Columbia coastal areas, bordeaux (4-4-50) plus a spreader (agral 2, lethelate, or penetrol) being effective preventatives on plants grown for seed. Only two applications of bordeaux were needed (1936-37) to protect the seed crop, since spraying after opening of the flowers is not necessary in such cases. Boniol, Dordinette, Copper hydro, and Burgundy mixture, with agral 2 as a spreader, all gave sufficient protection on plants grown for seed to warrant their trial on those grown as ornamentals.

Rubber blocks and wax for tree repairs: A new method to check decay. J. DOHERTY (*Florists Exch. and Hort. Trade World*, 92 (1939), No. 5, p. 10, figs. 3).—The new process makes use of rubber blocks as "sutures" followed by application of bolting wax used in the manner of dental "amalgam."

A decade of research in forest pathology. U. HARTLEY. (U. S. D. A.). (*Jour. Forestry*, 36 (1938), No. 9, pp. 908-912).—This is a review of research in the United States on seedling and plantation diseases, diseases in forests, naturalized diseases, decay of logging slash, and deterioration of killed timber and forest products. The present status and prospects for the future are also briefly discussed.

Dodder damages black locust seedlings at a Pennsylvania nursery. L. W. R. JACKSON and F. KAPLAN. (U. S. D. A.). (*Jour. Forestry*, 36 (1938), No. 7, p. 712).—Note on an outbreak of *Ouscuta arvensis* infestation on *Robinia pseudoacacia* seedlings, apparently brought in with clover seed.

Arsenate injury to black locust caused by drift. H. C. McNAMARA (*Miss. Farm Res. [Mississippi Sta.]*, 2 (1939), No. 7, p. 1).—A note reporting leaf drop and resulting reduction in growth of trees due to drift of calcium arsenate dusted by airplane for cotton bollweevil control.

Septoria canker of introduced and native hybrid poplars. J. E. BIEB (*Canad. Jour. Res.*, 17 (1939), No. 6, Sect. C, pp. 195-204, pls. 5).—It was found that in addition to leaf injury, *S. musiva* induces cankers on certain introduced poplars (*Populus ramosissima*, *P. peucephylla*, and *P. berolinensis*) and the native hybrids Northwest and Saskatchewan. Field observations and inoculations demonstrated that most of the inoculum for spring infection comes from ascospores of a *Myosphaerella* stage, and that the fungus enters the stems

through mechanical wounds, uninjured lenticels, leaf petioles, or stipules. Incipient cankers occur in the bark of the current season's wood, soon girdling both leading and side shoots. The cankers later spread from lateral branches to the main stem, developing into perennial cankers which ultimately girdle and kill the trees.

Laboratory tests of wood preservatives, J. LEIFERTZ (*Sri. Mo.*, 46 (1938), No. 6, pp. 576-579, figs. 4).—The method described involves the impregnation of small blocks of wood with the preservative under test, and their exposure in separate glass jars to the action of different fungi. After several weeks the effectiveness is rated on the amount and density of fungus growth, the decrease in weight of the samples, and their loss of mechanical strength. The untreated controls are valuable as indicators of the nature of the preservative from the standpoints of solubility, volatility, and chemical stability, and particularly of the strength lost by the treated blocks.

ECONOMIC ZOOLOGY—ENTOMOLOGY

George Henry Falkner Nuttall, 1862-1937 (*Parasitology*, 39 (1938), No. 4, pp. 403-418, pl. 1).—This biographical sketch is followed by a list of 190 scientific publications by G. H. F. Nuttall, issued from 1886 to 1938, inclusive.

Directory of field activities of the Bureau of Biological Survey, 1939 (*U. S. Dept. Agr., Misc. Pub.* 343 (1939), pp. II+117, figs. 3).

Conservation of wildlife, W. J. HAMILTON, JR. (In *Conservation in the United States*, Ithaca, N. Y.: Comstock Pub. Co., 1939, pp. 259-345, figs. 40).—This discussion relates to conservation of fish and fisheries (pp. 261-293), game and fur resources (pp. 294-327), and of other useful wildlife (pp. 328-345).

Wildlife food strip planting (*Rhode Island Sta. Misc. Pub.* [2] (1939), pp. [1]+3, fig. 1).—A practical account.

Legumes: Their erosion-control and wildlife values, E. H. GRAHAM (*U. S. Dept. Agr., Soil Conserv. Serv.*, 1939, *SCS-TP-23*, pp. [4]+102).—Following introductory accounts, this work presents an alphabetical annotated list of legumes which serve as food for wildlife (pp. 17-65), and an annotated list of birds (pp. 66-74) and of mammals (pp. 75-82) with the legumes they utilize. A list of 159 references to the literature cited and an index to legume names are included.

The problem of wildlife destruction by automobile traffic, L. M. DICKERSON (*Jour. Wildlife Mgmt.*, 3 (1939), No. 2, pp. 104-116, figs. 4).

Annotated list of Tennessee mammals, R. KELLOGG (*U. S. Natl. Mus. Proc.*, 86 (1939), No. 3051, pp. 245-303).—This annotated list of mammals of Tennessee is presented with a list of 44 references to the literature cited.

A census of red foxes and striped skunks in Clay and Boone Counties, Iowa, T. G. SCOTT and L. F. SELKO. (Iowa Expt. Sta.). (*Jour. Wildlife Mgmt.*, 3 (1939), No. 2, pp. 92-98).

Fall and winter food habits of Vermont bobcats, W. J. HAMILTON, JR., and B. P. HUNTER. (Cornell Univ. et al.). (*Jour. Wildlife Mgmt.*, 3 (1939), No. 2, pp. 99-103).—Identification of the stomach contents of 140 bobcats (*Lynx rufus rufus*), taken in Vermont from fall to late winter over a 3-yr. period, is reported upon. The findings indicate that the chief food of the bobcat consists of deer (much of which is carrion), mice, chiefly *Microtus* and *Peromyscus*, varying hares and cottontails, porcupines, squirrels, and grouse. "Shrews, muskrats, carrion, and blue jays were eaten less frequently. Such items as red and gray foxes, grass, poultry, fish, mink, and insects are also included in the winter dietary of the bobcat."

Central Wisconsin muskrat study, F. N. HAMERSTROM, JR., and J. BLAKE. (Univ. Wis. et al.). (*Amer. Midland Nat.*, 21 (1939), No. 2, pp. 514-520).—A list of food plants of the muskrat in central Wisconsin.

Rat surveys and rat proofing, B. E. HOLSENDORF (*Pests*, 7 (1939), No. 6, pp. 10-12).

Sanitation in fur farming: The use of disinfectants and insecticides in insect and disease control, R. LAW (*Soap*, 15 (1939), No. 2, pp. 93, 95, 117).

The migration of American birds, F. C. LINCOLN (*New York: Doubleday, Doran & Co.*, 1939, pp. XII+189, pls. 12, figs. 22).—In the preparation of this work, in addition to the original investigations in the field by the author and the extensive accumulations of data contained in the files of the U. S. D. A. Bureau of Biological Survey, free use was made of the writings of many others. Following an introduction and brief historical account, consideration is given to the origin and mechanics of, influence of the weather on, dangers in, times of, and distances covered in, migration; pelagic and vagrant migration; bird banding; evolution of migration routes; and the flyway systems.

Studies of breeding birds in the Allegany State Park, A. A. SANDERS (*N. Y. State Mus. Bul.* 318 (1938), pp. 160, figs. 77).—Forty-one species of birds found breeding in the Allegany State Park during a period of 12 summers for the months of July and August are reported upon.

The birds of Antigua, S. T. DANFORTH. (Univ. P. R.). (*Auk*, 51 (1934), No. 3, pp. 350-364).—In reporting further upon studies of birds in the West Indies (E. S. R., 81, pp. 669, 670), the author considers 61 species observed in Antigua, of which 42 were actually collected. As a result of the work 20 species previously unrecorded from the island are added to its known avifauna, bringing the total list of birds known from Antigua to 81, exclusive of 6 that have been doubtfully recorded and are listed hypothetically.

Supplement to "The birds of Antigua," S. T. DANFORTH (*Auk*, 56 (1939), No. 3, pp. 304, 305).—In this supplemental annotation, 6 species are added to the definitive list, making a total of 87 recorded from Antigua.

Geese and ducks of the world, N. KURODA ([*Tokyo: Shukyo-sha*], 1939, pp. [225], pls. 121).—Two hundred and thirty-two species and varieties of ducks and geese of the world, representing 13 subfamilies, are dealt with in this work, which is in Japanese.

Comparison of the food of white-necked ravens and crows in Oklahoma, R. H. IMLER. (U. S. D. A.). (*Wilson Bul.*, 51 (1939), No. 2, pp. 121, 122).

Winter losses from starvation and exposure of waterfowl and upland game birds in Ohio and other Northern States, M. B. TRAUTMAN, W. E. BILLS, and E. L. WICKLIFF (*Wilson Bul.*, 51 (1939), No. 2, pp. 86-104, figs. 8).—This contribution is presented with a list of 28 references to the literature.

A study of Wisconsin prairie chicken and sharp-tailed grouse, F. N. HAMERSTROM, JR. (*Wilson Bul.*, 51 (1939), No. 2, pp. 105-120, figs. 2).—A list of 22 references to the literature cited is included in this contribution.

Studies of the eastern ruffed grouse (*Bonasa umbellus umbellus*) in Michigan, L. W. FISHER (*Michigan Sta. Tech. Bul.* 166 (1939), pp. 46, figs. 9).—A report is made of studies started in Michigan in 1924 when a National Cooperative Committee was formed to determine what diseases or parasites might be responsible for the sudden decrease in the population of ruffed grouse. Work reported includes the history and distribution of ruffed grouse in Michigan, a description of ruffed grouse census areas, census methods, census data presented at length in tables and charts, habit studies, and some factors studied which determine the abundance of ruffed grouse (namely predators, parasites, and diseases), and control of cover. A summary of the parasitic infestation findings of

more than 300 ruffed grouse collected in the State has revealed the gizzard worm (*Ocheilospirura spinosa*) to be the parasite of most common occurrence, with the roundworm (*Ascaridia lineata*) and the eyeworm (*Oxyurisura petrovi*) ranking as close second in the number of infestations. Other parasites were the tapeworm (*Darainia tetraensis*), the proventricular worm (*Dispharynx spiralis*), the crop worm (*Thomox annulata*), the intestinal fluke, and the blood parasite *Leucocytozoon bonasae*. A bibliography of seven pages is included.

Seasonal movements of a low-density valley quail population, J. T. ENIEN, JR. (Univ. Calif.). (*Jour. Wildlife Mgmt.*, 3 (1939), No. 2, pp. 11-13, figs. 3).

Increase quail by improving their habitat, V. W. LEHMANN (Austin, Tex.: *State Game, Fish and Oyster Comm.*, 1937, pp. 44, figs. 13).—This report, based upon field observations conducted since the fall of 1927 in all important quail habitats in Texas and examinations during the fall of 1935 of 2,000 winter quail stomachs collected throughout the State, is presented with a list of 26 references to the literature reviewed.

Additional information on the food of the American woodcock, O. S. PEITINGILL, JR. (*Wilson Bul.*, 51 (1939), No. 2, pp. 78-82).—This contribution supplements the earlier work noted (E. S. R., 76, p. 211).

Life histories of North American woodpeckers: Order Piciformes, A. C. BENT (U. S. Natl. Mus. Bul. 174 (1939), pp. VIII+334, pls. 39).—This is the twelfth in a series of bulletins on the life histories of North American birds (E. S. R., 80, p. 509).

Dispharynx pipilonis, a new spiruroid nematode from the red-eyed towhee (*Pipilo erythrophthalmus erythrophthalmus* (Linn.)), O. W. OLSEN. (Minn. Expt. Sta. et al.). (*Amer. Midland Nat.*, 21 (1939), No. 2, pp. 472-475, figs. 4).—Under the name of *D. pipilonis* a description is given of a new species collected from the proventriculus of the red-eyed towhee in Kentucky. A key to the species of the genus which supplements that issued by Cram in 1927 (E. S. R., 53, p. 157) includes five species since described.

Trout streams: Conditions that determine their productivity and suggestions for stream and lake management, P. R. NEEDHAM (Ithaca, N. Y.: Comstock Pub. Co., 1938, pp. X+233, figs. [75]).—This work includes discussions of predatory animals occurring along trout streams, parasites, stream insects which serve as food, and crustaceans, snails, and clams (pp. 73-112), also a discussion of food selection as shown by trout (pp. 113-126) and the distribution of trout foods (pp. 127-153).

Fifty years of entomology research, J. R. WATSON. (Fla. Expt. Sta.). (*Citrus Indus.*, 19 (1938), No. 11, pp. 3, 23, fig. 1).

The role of arrhenotoky in the adaptation of insects, S. E. FLANDEBS. (Calif. Citrus Expt. Sta.). (*Science*, 90 (1939), No. 2326, p. 82).

The nomenclature of categories lower than species, C. W. SABBOSKY. (Mich. Expt. Sta.). (*Ent. News*, 50 (1939), No. 7, pp. 197-203).

[Contributions on economic insects, insecticides, and insect control] (U. S. Dept. Agr., Bur. Ent. and Plant Quar., 1939, E-469, pp. 19; E-470, pp. 17, pls. 9; E-471, pp. 12, pls. 7; E-472, pp. 2; E-473, pp. 13, pls. 2; E-474, pp. 8; E-475, pp. 37, figs. 37; E-476, pp. 9, pls. 3; E-477, pp. 18; E-478, pp. 14; E-479, pp. 11, pls. 8; E-480, pp. 4; E-481, pp. 4; E-482, pp. 14; E-483, pp. 56).—The following contributions are in continuation of this series (E. S. R., 81, p. 242): Insects of the Castor-Benn. by G. Myers (E-469); Practical Methods of Mormon Cricket Control, by C. Wakeland, W. B. Mabey, and F. T. Cowan (E-470); Status of White Pine Blister Rust Control on January 1, 1939 (E-471); The European Earwig and Its Control, by C. W. Getzenbauer (E-472); A Preliminary Report on the Influence of Stock on Supersedure, or Loss, of Queen Bees,

by C. L. Farrar and C. W. Schaefer (E-473); The Strawberry Weevil and Its Control, by W. A. Thomas (E-474); Keys for the Identification of Some Lepidopterous Larvae Frequently Intercepted at Quarantine, by H. W. Capps (E-475); The Use of Oil for Earworm Control in Sweet Corn, by G. W. Barber (E-476); List of Common Names Used for Species of *Deris* in Connection With Insecticidal Properties, by R. C. Roark (E-477); Recommendations for the Control of Certain Insects Attacking Vegetables, Strawberries, and Raspberries, by W. H. White (E-478); Aids to the Identification of the Mormon and Coulee Crickets and Their Allies (Orthoptera: Tettigonidae, Gryllacrididae), by A. B. Gurney (E-479); Results of Studies on Diphenylamine As a Wound Protector Against the Screwworm (*Cochliomyia americana* C. and P.) (E-480) and Diphenylamine As a Wound Protector Against the Screwworm (*Cochliomyia americana* C. and P.) (E-481), both by R. Melvin, H. E. Parish, E. F. Knippling, and R. C. Bushland; The Effect on Plants of Methyl Bromide Fumigation in Japanese Beetle Treatment Tests—Preliminary Report, by H. C. Donohoe and V. A. Johnson (E-482); and A Bibliography of *Quassia*, by R. L. Busbey (E-483).

Insect populations (*Ecol. Monog.* 9 (1939), No. 3, pp. 25f-320, figs. 2).—Contributions presented in a symposium on insect populations at a joint meeting of the Ecological Society of America, Entomological Society of America, and the American Association of Economic Entomologists at Richmond, Va., in December 1938 are: Insect Population Problems in Relation to Insect Outbreak, by R. N. Chapman (pp. 261-269) (Hawaii, Pineapple Prod. Expt. Sta.); Population Studies of Soil Insects, by K. M. King (pp. 270-296); Populations of Social Insects, by A. E. Emerson (pp. 297-300); Forest Insect Populations, by S. A. Graham (pp. 301-310); and Insect Populations in Relation to Biological Control, by H. S. Smith (pp. 311-320) (Calif. Citrus).

Proceedings Seventeenth Annual Meeting of the North Central States Entomologists (*North Cent. States Ent. Proc.* 17 (1938), pp. 17-20, 23, 25-29, 31, 32, 34, 39-43, 55-83, 84-92, 92-96, 96-99, 99-101, 103-106, 107-110).—Among the contributions presented at the annual meeting held in March 1938 and included in this mimeographed report are: Some Recent Developments of the Locust Borer Problem, by W. L. Baker (pp. 17, 18); Breeding Plants for Resistance to Insects, by G. H. Stringfield (p. 23); Promising New Insecticides Developed by the [U. S. D. A.] Division of Insecticide Investigations, by R. C. Roark (pp. 25-29); Some Interesting Data From a Study of Grassland Insects, by D. A. Wilbur (p. 31); Armyworms—Forecasting, Migrating, Habits, and Control, by W. P. Flint (pp. 33, 34); Insect Hazards and Preventive Measures Possible to Grain Stored on Farms Under the Proposed Ever Normal Granary Plan, by R. T. Cotton (pp. 39, 40); The Corn Borer Situation in the Lake States Area in 1937, by W. A. Baker (pp. 41, 42); Present Status of Corn Borer in Indiana and Work in Progress, by G. A. Ficht (pp. 42, 43); Codling Moth—New Developments on Life History and Control, by C. R. Cutright and G. E. Marshall (pp. 55-57), and Use of Bait Traps as an Extension Project, by G. E. Lecker (p. 58); Oriental Fruit Moth—Parasitism and Infestation, by B. F. Driggers (pp. 59-61); Chemical Control, by M. D. Farrar (p. 62), and Cultural Control, by G. E. Marshall (pp. 62, 63); Tests With Dilutant Oil Containing 2,4-Dinitro-cyclohexyphenol on Peach (pp. 63, 64) and Effectiveness of Ethylene Dichloride at Low Temperatures for Control of Peach Borer (p. 64), both by S. C. Chandler; Control of Flat-Headed Borers, by J. S. Houser (pp. 64, 65); Apple Leafhopper—Life Histories of Important Species, by D. M. DeLong (pp. 65, 66), and White Apple Leafhopper Control, by H. M. Steiner (pp. 66, 67); Recent Developments in Grape Insect Research, by G. A. Runner (pp. 67-69); Biology and Control of

Strawberry Leaf Roller, by R. L. Park and P. G. Lumsden (Kans. Expt. Sta.) and R. B. Neiswander (pp. 69-72); Control of Twining Cynipids, by G. A. Ficht and R. Hutson (pp. 72-74); Control of Raspberry cane Borer and Related Species, by E. L. Chambers (p. 74); Effect of Fruit Tree Removal by W. P. A. on Insect Populations in Commercial Orchards, by F. G. Anderson (p. 75); Safeners for Use With Calcium Arsenate, Zinc Arsenate, and Lead Arsenate in Different Spray Combinations, by H. F. Dietz (pp. 75-77); The Quantitative Approach to the Problems of Plant Resistance to Insect Attack, summarized by L. L. Huber (pp. 78-82); Insect Pollination of Alsike Clover, by W. E. Dunham (p. 83); 4-H Club Work in Beekeeping, by G. E. Lehker (p. 83); Evaluation of Biotic Control, by S. A. Graham (p. 84); Evaluation of Biological Control Through Parasites and Predators and the Relative Importance of Each Group, by A. Peterson (p. 85); Should Our Cultural Practices be Correlated With Biological Control? by L. M. Peairs (p. 85); Should Our Insecticide Program be Correlated With Biological Control? by P. Garman (pp. 85, 86); Some Important Factors in Biological Control, by C. P. Clausen (pp. 86, 87); Possibilities of Biological Control of Greenhouse Insects Thru Natural Enemies, by C. C. Compton and J. H. McLeod (pp. 88, 89); Importance of Continued Surveys To Determine Parasite Effectiveness, by R. B. Neiswander (p. 89); The Present Status of Biological Control of the European Corn Borer, by W. A. Baker (pp. 89, 90); Newer Developments and Present Trends of Research in the Control of Greenhouse Insects, by H. F. Dietz (pp. 90, 91); Thrips and Red Spider and Their Control Under Glass, by C. C. Compton and C. R. Neiswander (pp. 92, 93); Cyclamen Mite and Broad Mite Control in the Greenhouse, by C. C. Compton (p. 93); An Earwig Destructive to Greenhouse Radish, by C. R. Neiswander (p. 94); The Garden Symphlyid, by J. S. Houser (pp. 94, 95); Control of Green Bean Pests With Special Reference to Leafhopper, Mexican Bean Beetle, and Red Spider, by N. F. Howard and L. H. Shropshire (pp. 96, 97); The Striped Cucumber Beetle and Wilt Disease, by G. E. Gould (p. 97); Control of Cabbage Insects, by L. H. Shropshire (p. 98); Control Experiments Against the Tarnished Plant Bug, by G. E. Gould (p. 99); Squash Vine Borers, by R. Hutson (p. 100); Control of Tomato Fruit Worm, by L. H. Shropshire and G. E. Gould (pp. 100, 101); Relation of Mosquitoes to Encephalomyelitis of Horses (pp. 103, 104) and Distribution, Importance, and Control of the Sheep Bot Fly (p. 104), both by F. C. Bishopp; Testing of Fly Sprays, by W. A. Simonton (pp. 104, 105); Electric Insect Traps and Screens, by T. H. Parks (pp. 105, 106); Rubberized Fumigating Bags for Individual Articles of Household Furniture, by R. T. Cotton (p. 107); Life History and Habits of Six Species of Cockroaches, by G. E. Gould (pp. 107, 108); A New Ant to Consider in the North Central States—the Crazy Ant (*Paratrechina [Prenolepis] longicornis*), by W. E. McCauley (p. 108); Proprietary Termite Control Treatments, by J. J. Davis (pp. 109, 110); and A Termite Control Project, by G. E. Lehker (p. 110).

[Contributions on economic insects and insect control] (*Northwest Assoc. Hort., Ent., and Plant Pathol., Moscow, Idaho, 4 (1938), Abs. Papers*, pp. 9-12).—Among the entomological contributions presented at a meeting held in Idaho in July 1938, abstracts of which are included in this mimeographed report, are the following: Progress in the Biological Control of Fruit Insects at Parma, Idaho, by R. W. Haegele (p. 9); Wireworms and Their Control in the Pacific Northwest, by M. C. Lane (pp. 9, 10) (U. S. D. A.); Dissemination of Introduced Insect Pests in Washington, by L. G. Smith (p. 10); Resistance of Winter Wheats to Hessian Fly, by W. R. Foster and C. E. Jeffery (pp. 10, 11); Pea Aphid Populations on Alfalfa and Canning Peas During 1937, by R. D. Elchmann (p. 11) (Wash. Expt. Sta.); Experiments With Phenothiazine, by C. W. Murray (p. 11)

(U. S. D. A.) ; The Control of the Hairy Spider Beetle (*Ptinus villiger* Reit.) by Means of Poisoned Baits, by W. Downes and H. Andison (pp. 11, 12) ; The Distribution of Pea Weevil Infestations in the Palouse Area of Northern Idaho and Eastern Washington, by T. A. Brindley and F. G. Hinman (p. 12) (U. S. D. A.) ; and Field Experiments for the Control of the Beet Leafhopper in Idaho, 1936-37, by J. R. Douglass, C. Wakeland, and J. A. Gillett (p. 12) (U. S. D. A., Idaho Sta., et al.).

[Studies on economic zoology and entomology] (*Miss. Farm Res. [Mississippi Sta.]*, 2 (1939). Nov. 3, p. 3; 6, pp. 1, 6, 8).—Brief articles are included as follows: No. 3, Crawfish Control by Simple Treatment, by C. Lyle; No. 6, July Poison for Weevils Is Suggested, by C. Lyle, and Little Danseur of Injury From Use of Calcium Arsenate, by R. Coleman.

[Work in entomology by the New Mexico Station] (*New Mexico Sta. Rpt.* 1938, pp. 45-55, figs. 7).—The work of the year referred to (E. S. R., 79, p. 76) includes codling moth investigations, namely, (1) relation of bacteria to fermentation and attractiveness, (2) attractancy of chemicals isolated from fermenting baits and their comparison with members of homologous or related series, (3) improvements in trap design and manipulation, and (4) comparison of insecticides used as supplements for lead arsenate in summer cover spray; and further tests with soil insecticides for control of subterranean larvae of the California prionus.

[Work in entomology by the Rhode Island Station] (*Rhode Island Sta. Rpt.* [1938], pp. 20, 23).—Brief reference is made (E. S. R., 79, p. 504) to the treatment of early cabbage plants with corrosive sublimate to protect them from root maggots, the use of rotenone for the control of the green cabbageworm on cabbage and cauliflower, and control of the webworm by the application of arsenate of lead.

[Contributions on economic insects] (*Wash. State Hort. Assoc. Proc.*, 34 (1938), pp. 7-13, 31-33, 123-140, 144-149, 149, 150, 151, 152, 153, 154, 155, 156, 157, 158, 159, 160, 161, 162, 163, 164, 165, 166, 167, 168, 169, 170, 171, 172, 173, 174, 175, 176, 177, 178, 179, 180, 181, 182, 183, 184, 185, 186, 187, 188, 189, 190, 191, 192, 193, 194, 195, 196, 197, 198, 199, 200, 201, 202, 203, 204, 205, 206, 207, 208, 209, 210, 211, 212, 213, 214, 215, 216, 217, 218, 219, 220, 221, 222, 223, 224, 225, 226, 227, 228, 229, 230, 231, 232, 233, 234, 235, 236, 237, 238, 239, 240, 241, 242, 243, 244, 245, 246, 247, 248, 249, 250, 251, 252, 253, 254, 255, 256, 257, 258, 259, 260, 261, 262, 263, 264, 265, 266, 267, 268, 269, 270, 271, 272, 273, 274, 275, 276, 277, 278, 279, 280, 281, 282, 283, 284, 285, 286, 287, 288, 289, 290, 291, 292, 293, 294, 295, 296, 297, 298, 299, 300, 301, 302, 303, 304, 305, 306, 307, 308, 309, 310, 311, 312, 313, 314, 315, 316, 317, 318, 319, 320, 321, 322, 323, 324, 325, 326, 327, 328, 329, 330, 331, 332, 333, 334, 335, 336, 337, 338, 339, 340, 341, 342, 343, 344, 345, 346, 347, 348, 349, 350, 351, 352, 353, 354, 355, 356, 357, 358, 359, 360, 361, 362, 363, 364, 365, 366, 367, 368, 369, 370, 371, 372, 373, 374, 375, 376, 377, 378, 379, 380, 381, 382, 383, 384, 385, 386, 387, 388, 389, 390, 391, 392, 393, 394, 395, 396, 397, 398, 399, 400, 401, 402, 403, 404, 405, 406, 407, 408, 409, 410, 411, 412, 413, 414, 415, 416, 417, 418, 419, 420, 421, 422, 423, 424, 425, 426, 427, 428, 429, 430, 431, 432, 433, 434, 435, 436, 437, 438, 439, 440, 441, 442, 443, 444, 445, 446, 447, 448, 449, 450, 451, 452, 453, 454, 455, 456, 457, 458, 459, 460, 461, 462, 463, 464, 465, 466, 467, 468, 469, 470, 471, 472, 473, 474, 475, 476, 477, 478, 479, 480, 481, 482, 483, 484, 485, 486, 487, 488, 489, 490, 491, 492, 493, 494, 495, 496, 497, 498, 499, 500, 501, 502, 503, 504, 505, 506, 507, 508, 509, 510, 511, 512, 513, 514, 515, 516, 517, 518, 519, 520, 521, 522, 523, 524, 525, 526, 527, 528, 529, 530, 531, 532, 533, 534, 535, 536, 537, 538, 539, 540, 541, 542, 543, 544, 545, 546, 547, 548, 549, 550, 551, 552, 553, 554, 555, 556, 557, 558, 559, 560, 561, 562, 563, 564, 565, 566, 567, 568, 569, 570, 571, 572, 573, 574, 575, 576, 577, 578, 579, 580, 581, 582, 583, 584, 585, 586, 587, 588, 589, 590, 591, 592, 593, 594, 595, 596, 597, 598, 599, 600, 601, 602, 603, 604, 605, 606, 607, 608, 609, 610, 611, 612, 613, 614, 615, 616, 617, 618, 619, 620, 621, 622, 623, 624, 625, 626, 627, 628, 629, 630, 631, 632, 633, 634, 635, 636, 637, 638, 639, 640, 641, 642, 643, 644, 645, 646, 647, 648, 649, 650, 651, 652, 653, 654, 655, 656, 657, 658, 659, 660, 661, 662, 663, 664, 665, 666, 667, 668, 669, 670, 671, 672, 673, 674, 675, 676, 677, 678, 679, 680, 681, 682, 683, 684, 685, 686, 687, 688, 689, 690, 691, 692, 693, 694, 695, 696, 697, 698, 699, 700, 701, 702, 703, 704, 705, 706, 707, 708, 709, 710, 711, 712, 713, 714, 715, 716, 717, 718, 719, 720, 721, 722, 723, 724, 725, 726, 727, 728, 729, 730, 731, 732, 733, 734, 735, 736, 737, 738, 739, 740, 741, 742, 743, 744, 745, 746, 747, 748, 749, 750, 751, 752, 753, 754, 755, 756, 757, 758, 759, 760, 761, 762, 763, 764, 765, 766, 767, 768, 769, 770, 771, 772, 773, 774, 775, 776, 777, 778, 779, 780, 781, 782, 783, 784, 785, 786, 787, 788, 789, 790, 791, 792, 793, 794, 795, 796, 797, 798, 799, 800, 801, 802, 803, 804, 805, 806, 807, 808, 809, 810, 811, 812, 813, 814, 815, 816, 817, 818, 819, 820, 821, 822, 823, 824, 825, 826, 827, 828, 829, 830, 831, 832, 833, 834, 835, 836, 837, 838, 839, 840, 841, 842, 843, 844, 845, 846, 847, 848, 849, 850, 851, 852, 853, 854, 855, 856, 857, 858, 859, 860, 861, 862, 863, 864, 865, 866, 867, 868, 869, 870, 871, 872, 873, 874, 875, 876, 877, 878, 879, 880, 881, 882, 883, 884, 885, 886, 887, 888, 889, 890, 891, 892, 893, 894, 895, 896, 897, 898, 899, 900, 901, 902, 903, 904, 905, 906, 907, 908, 909, 910, 911, 912, 913, 914, 915, 916, 917, 918, 919, 920, 921, 922, 923, 924, 925, 926, 927, 928, 929, 930, 931, 932, 933, 934, 935, 936, 937, 938, 939, 940, 941, 942, 943, 944, 945, 946, 947, 948, 949, 950, 951, 952, 953, 954, 955, 956, 957, 958, 959, 960, 961, 962, 963, 964, 965, 966, 967, 968, 969, 970, 971, 972, 973, 974, 975, 976, 977, 978, 979, 980, 981, 982, 983, 984, 985, 986, 987, 988, 989, 990, 991, 992, 993, 994, 995, 996, 997, 998, 999, 1000).

The Entomological Branch (*Canada Min. Agr. Rpts.*, 1936-37, pp. 81-90; 1937-38, pp. 81-102).—Further reports are made of the appearance of and control work with economic insects in Canada (E. S. R., 78, p. 512).

[Contributions on economic insects and related pests and their control] (*Jour. Southeast. Agr. Col., Wye, Kent*, No. 44 (1939), pp. 37, 38, 59-91, 103-108, 180-182, figs. 24).—Contributions presented include The Control of Hop Red Spider—Some Recent Experiences (pp. 37, 38), A Note on Tyroglyphid Mites [*Cosmoglyphus* sp.] Occurring in Silage and on Lily of the Valley (pp. 59, 67), and Investigations on the Insect and Allied Pests of Cultivated Mushrooms—XIII, Another Tyroglyphid Mite [*Caloglyphus berlesii* Mich. 1903] (pp. 68-72) (E. S. R., 81, p. 69), all by S. G. Jary; Investigations on Insect Pests of Brassica Seed Crops in Romney Marsh, I] (pp. 73-83) and II (p. 84), and Investigations on Wireworms. I (pp. 85-91), all by S. G. Jary and M. D. Austin; Hive Bees in Relation to Commercial Fruit Production, by C. H. Hooper (pp. 103-108); and

Notes on Diplopoda—VI, The Recognition of Some Millipedes of Economic Importance, III, by S. W. Rolfe (pp. 180-182) (E. S. R., 81, p. 69).

[Contributions on economic insects and insecticides] (*East Malling [Kent] Res. Sta. Ann. Rpt.*, 26 (1938), pp. 1-6-203, 250-252, 256-258, pls. 3, figs. 1).—Contributions presented (E. S. R., 81, p. 69) relating to observations and work in Great Britain include Notes on Some Interesting Insects Observed in 1938, by A. M. Massee (pp. 180-185); The Control of Strawberry Aphis [*Capitophorus fragariae* Theob.] and Tarsouenid Mite, by R. M. Greenslade and A. M. Massee (pp. 186-190); The Bramble Shoot-Webber *Agrotis ulmanniana* L., by G. H. L. Dicker (pp. 191-198); Spray Residue Investigations—III, The Influence of Petroleum Oil and of Lime-Sulphur on the Retention of Lead Arsenate on Apples, by H. Shaw and W. Steer (pp. 199-203); Suggestions for Control of Strawberry Aphis [*Capitophorus fragariae* Theob.] by R. M. Greenslade and A. M. Massee (pp. 250-252); and Investigations With Insecticides, by W. Steer (pp. 256-258).

Insect and other pests of 1938. A. E. CAMERON (*Highland and Agr. Soc. Scot. Trans., 5. ser.*, 51 (1939), pp. 136-174, figs. 16).—A discussion of the more important insect and tick pests of Scotland (E. S. R., 81, p. 69).

[Contributions on economic insects] (*Bul. Soc. Fouad 1. Ent.*, 22 (1938), pp. 1-9, 36-59, 67-109, 233-283, 286-345, 357-395, pls. 10, figs. 95).—Among the contributions presented are the following: Insects Injurious to Vegetables and Shrubs in the Jordan Valley, Huleh Area, and the Upper Galilee, by A. Granberg (pp. 1-9); Description of a New Species of *Leptonuxia* Parasitic in *Phenacoccus hirsutus* Green, by H. Compere (pp. 36-38) (Calif. Citrus Expt. Sta.); Studies on the Mediterranean Fruit-Fly (*Ceratitis capitata* Wied.)—I. The Structure and Operation of the Reproductive Organs, by A. D. Hanna (pp. 59-59); The Terminalia of the Genus *Wohlfahrtia* B. & B. and Those of Some Allied Genera, Together With Notes on the Natural Grouping of the Species of the Subfamilies Sarcophaginae and Miltogrammatinae, by W. S. Patton (pp. 67-109); Constant Temperature Hot Air Sterilizer for the Control of *Ephestia* and *Myelois* on Dates, by M. Shafik (pp. 233-263); A Mud Brick Oven for Drying Dates and Controlling *Ephestia*, by M. Shafik and A. L. Hilmy (pp. 265-277); A Brief Note on the Relation Between the Physiological Condition of Plants and Insect Attack, by H. Priesner (pp. 279-283); Notes on the Embryonic and Post-Embryonic Development of *Calandra oryzae* (Linn.) and Related Coleoptera, by K. Mansour (pp. 286-299); Efficiency of Commercial Sodium Cyanide and Sulphuric Acid in Liberating Hydrocyanic Acid Gas for the Fumigation of Citrus Trees in Egypt Against Scale Insects, by M. Shafik, A. Amer, and A. L. Hilmy (pp. 301-345); and The Ideal Spray Emulsion for the Control of Scale Insects on Citrus in Egypt, by M. Shafik and M. Husni (pp. 357-395).

[Contributions on economic zoology and entomology] (*Indian Sci. Cong. Proc. [Hyderabad]*, 24 (1937), pp. 300, 301, 303, 304, 307, 308, 309, 368-372).—Included among the abstracts of contributions presented at the twenty-fourth Indian Science Congress held at Hyderabad in January 1937 are the following: The Anatomy of *Glyptidilus annandalei* Mich., by K. Bhaskaran Nair (p. 300); Economic Aspect of Insect Parasitism, by T. V. R. Ayyar (pp. 300, 301); Biological Control in the Lac Industry, by P. M. Glover (p. 301); The Alimentary Canal of *Epilachna indica* (Coccinellidae: Coleoptera), With a Discussion on the Activities of the Mid-Gut Epithelium, by S. Pradhan (p. 303); Experiments on the Sterility of *Ephestia kuehniella* Z. in Relation to High Temperature (30° C.), by D. P. Raichoudhury and S. E. Jacobs (p. 304); Soil Moisture and Incubation Period in *Schistocerca gregaria* Forsk. Eggs, by M. A. Husain and T. Ahmad (p. 307); Cestode Parasites of Sheep and Goats in the Punjab, by M. Amin (p. 308); Some Coccinellids of the Punjab, by A. P. Kapur (p. 309); Cotton Jassids

and Hairiness of Cotton Plant, by M. A. Husain and K. B. Lal (p. 368); The Bird Enemies of the Cotton Leaf Roller *Sylepta acroqata* Fb. at Khanewal (Multan, Punjab), by M. A. Husain and H. Bhalla (p. 368); Observations on the Life-History of Pink Bollworm *Platyedra gossypiella* Saund. at Parbhani (Deccan), by H. D. Nangpal, N. T. Nadkerny, and T. E. Krishnaswamy (p. 368); The Tur-Pod Fly *Agromyza obtusa* Mall., by T. Ahmad (pp. 368, 369); A New Cecidomyid Pest *Dasyneura lini* Barnes of Linseed in India, by H. S. Pruthi and H. L. Bhatia (p. 369); Life-History and Biology of the Weevil Borer *L[igustica] truncatulus* of Amaranthus, by T. Ahmad (pp. 369, 370); Studies on *Stenobracon nicrillei*, a Parasite of the Sugarcane White Moth Borer *Scirpophaga*, by M. C. Cherian and P. Israel (p. 370); A New Enemy of the Indian Honey Bee, by M. C. Cherian and V. Mahadevan (p. 370); Notes on the Life-History and Habits of *Dacus brevistylus* (Family Trypetidae), a Pest of *Coccinia indica* Fruits, by M. C. Cherian and C. V. Sundaram (p. 370); Studies on the Incidence of the Swarming Caterpillar [*Spodoptera mauritia* Boisdu.] of Paddy, by M. C. Cherian and K. P. Anantanarayanan (p. 371); The Important Insect Problems Affecting the Cultivation of Coconuts in Cochin State and *Oryza retusa* F. as a Pest of "Kole Paddy" in Cochin, both by C. S. Venkatasubban (p. 371); and Marriage Flight and Colony Founding of *Camponotus* (Tanae-Myrmex) *compressus* Latr., by P. N. Krishna Iyer (pp. 371, 372).

[Contributions on economic zoology and entomology] (*Indian Sci. Cong. Proc. [Calcutta], 25 (1938), pts. 3, pp. 158, 159, 162, 173, 174, 175, 176, 177, 178, 179, 180, 181, 182-192, 274; 4, pp. 78-81*).—Among the contributions presented at the twenty-fifth Indian Science Congress held at Calcutta in January 1938 are the following: The Incidence of Cestode Parasites Among Ovine Hosts in the Punjab (p. 158), Two New Species of *Aritellina* (Cestoda) From Ovis in the Punjab (pp. 158, 159), and The Occurrence of the Cestode *Helicometra giardi* (Moniez 1879) in Indian Sheep (p. 159), all by M. Amin; on a New Nematode *Pseudaspidodera jnanendrac* n. sp. From Peafowl (*Pavo cristatus*), by G. K. Chakravarty (p. 159); Diseases Transmitted by Indian Species of Ticks in India and Other Countries and the Possibility of Their Prevention Through Biological Control, by M. Sharif (p. 162); Some Reversal Changes Among Locusts and Other Acrididae and the Probable Importance of the Third Instar, by M. L. Roonwal (pp. 173, 174); A Preliminary Note on the Probable Existence of Seasonal Migration Among the Solitary Phase Individuals of *Locusta migratoria* in North-West India, by Y. R. Rao and D. R. Bhatia (p. 174); On Two Chalcidoid Parasites on Moths [*Brachymeria euplocae* (Westw.)], With a Description of *Eupelmus terminaliae* sp. nov., by H. A. Hafiz (p. 175); Some Species of the Scolytidae (Coleoptera) From Mysore, With Special References to the Occurrence of *Stephanoderes hampei* Ferr in Dry Cotton Fruit Stalks and Carpels, by T. V. Subramanian (pp. 175, 176); An Extra Hopper Stage in the Desert Locust *Schistocerca gregaria* Forsk., by C. B. Mathur (p. 177); On the Thoracic Mechanism of the Pulse Beetle *Bruchus quadrimaculatus* Fabr., by D. Mukerji (p. 177); Effect of Different Sugars on the Longevity of *Microbracon greeni* Ashm., by S. N. Gupta (p. 178); Further Observations on the Role of Blood in Oviposition in Culicidae, by S. K. Sen (pp. 178, 179); Length of Life of Pink Bollworm Moth and Its Correlation With Temperature and Humidity, by H. D. Nangpal and V. N. Poorna Pregna (p. 179); The Influence of Temperature on the Rate of Growth and Size in the Desert Locust *Schistocerca gregaria* Forsk., by Abdul Haq (p. 180); Life-History and Biology of *Monophlebus stebbingi*, by A. B. Misra and S. R. M. Rao (pp. 181, 182); On the Habits and Life-History of *Amphipsyche indica* Martynov. (Trichoptera), by H. A. Hafiz (p. 182); Two Caterpillars of Economic Im-

portance Not Recorded Before in S. India and The Economic Role of South Indian Horn Worms (*Sphingidae*), both by T. V. R. Ayyar (p. 182); The High Fecundity of the Epilachna Beetles *Epilachna vigintio[cto]punctata* Fabr. and *Epilachna dodecastigma* Muls. in Cochin, by C. S. Venketasubban and Neelakanta Iyer (pp. 182, 183); The Cotton Jassid *Eurpasa dirastus* Distant, by M. A. Husain and K. B. Lal (p. 183); Studies and Observations on the Incidence and Control of *Spodoptera incurtita* (Doisd.), a Major Pest of Rice in Cochin, by C. S. Venketasubban (p. 183); Observations on the Sugarcane Borer Incidence at the Government Sugarcane Farm, Jorhat, by K. C. Sharma (pp. 183, 184); *Semiothisa (Macaria) pervolvata*, a Geometrid Pest of Daincha (*Desbania aculeata*), by M. C. Cherian and B. Rangiah Pillai (p. 184); Studies on *Laphygma exigua* Hb. and its Natural Enemies, by M. C. Cherian and M. S. Kylasam (p. 184); Effect of Bollworm Attack on the Number of Seed, Lint Weight, Seed Weight, and Ginning Percentage of Clean Locks in Partially Damaged Bolls, by H. D. Nangpal (pp. 184, 185); Incidence of Spotted Bollworm Attack on Cotton at Parbhani (Hyderabad-Dn), by H. D. Nangpal, N. T. Nadkarni, and T. E. Krishnaswami (p. 185); A Caterpillar Pest of Champaka (*Mitella*) in South Malabar District, by T. V. R. Ayyar (p. 185); A New Cecidomyiad Pest of *Moringa*, by M. C. Cherian and M. Basheer (p. 185); The Amaranthus Stem Weevil of S. India (*Lixus brachyrrhinus* Boh.) and Its Parasites, by P. N. K. Ayyar (pp. 185, 186); Measures Against Sugarcane Pests in the Jullundur Circle, by M. Fateh-ud-din and B. D. Singh (p. 186); An Annotated Conspectus of the Insects Affecting Fruit Crops in South India, by T. V. R. Ayyar (p. 186); Some Observations on the Bionomics and Control of Fruit Fly Pests in the N.-W. Frontier Province, by H. S. Pruthi and H. L. Bhatia (p. 187); On *Agrilus citri* Thery (Buprestidae), a Pest of *Citrus acida* in Bihar, by B. B. Bose (p. 187); Studies on the Coconut Beetle *Oryctes rhinoceros* Linn. in South India, by M. C. Cherian and K. P. Anantanarayanan (p. 187); Preliminary Studies on the Biology of the Mite (*Tetranychus* sp.), by A. N. Sapra (pp. 187, 188); Mass Breeding of *Microbracon greeni* Ashm.—an Ectoparasite of the Larva of *Eublemma amabilis* Moore Predaceous on Lac, by S. N. Gupta (p. 188); A Preliminary Note on the Bionomics and Mass-Breeding of *Trichogramma* sp., by A. G. Hussain (pp. 188, 189); A Trichogrammid Chalcid Parasite of the Egg of *Eublemma amabilis* Moore Predaceous on Lac, by J. N. Singh, P. S. Negi, M. P. Misra, and S. N. Gupta (p. 189); *Apanteles tachardiae* Cam. and Endoparasite of the Larva of *Holcocera pulverea* Meyr. Predaceous on Lac, by M. P. Misra, S. N. Gupta, and J. N. Singh (p. 189); *Pareuderus torymoides* Ferr., an Egg Parasite of the Amaranthus Borer *Lixus truncatulus* (pp. 189, 190) and a Chalcid Parasite of the Linseed Midge *Dasyneura lini* (p. 190), both by T. Ahmad; Notes on a Braconid Parasite of the Wax Moth (*Galleria mellonella*), by M. C. Cherian and S. Ramachandran (p. 190); *Rhaconotus scirpophaga*, a Parasite of the Sugarcane White Moth Borer (*Scirpophaga*), by M. C. Cherian and M. Israel (pp. 190, 191); The Bacterial Flora in the Gut of the Larvae of the Cocoa Moth *Ephestia elutella* Hb., by S. E. Jacobs and D. P. Raichoudhury (p. 191); The Cotton White-Fly As a Vector of the Leaf Curl Disease of Tobacco, by H. S. Pruthi (p. 191); The Relative Efficiency of Some Methods for Comparing Jassid Population in Cotton Fields, by K. B. Lal (pp. 191, 192); Observations on the Bionomics of the Ox Warble-Fly *Hypoderma lineatum*, by B. N. Soni (p. 274); and biological control of insect pests (pp. 78-81).

[Work with economic insects in 1937] (*Philippine Bur. Plant Indus. Ann. Rpt., 1937, pp. 76-78*).—Report is made of laboratory studies and field control work with economic insects, particularly grasshoppers.

Meadow and pasture insects, H. Osborn (*Columbus, Ohio: Educators' Press, [1939], pp. VIII+288, figs. 103*).—This work, with a foreword by L. O. Howard, is presented in 13 chapters and an appended list of 296 references to the literature. Preceding the chapters presenting the subject under the more important orders of insects found in meadow and pasture are others on the ecology of the meadow (pp. 12-42), animal groups in the meadow fauna (pp. 43-55), the insect population (pp. 56-59), and general control measures for meadow and pasture insects (pp. 60-69).

The dodder and its insects, W. D. PIERCE (*Bul. South. Calif. Acad. Sci., 38 (1939), No. 1, pp. 43-53, fig. 1*).—A report is made of insects, particularly weevils, taken in or reared from the flowers of *Cuscuta californica* on the El Segundo, Calif., sand dunes. Three species of the genus *Smicronyx* and one of the genus *Berginus* are described as new.

[Contributions on sugarcane insects and rodents and their control] (*Internatl. Soc. Sugar Cane Technol. Cong. [Baton Rouge, La.] Proc., 6 (1938), pp. 89-112, 223-261, 361-386, 421-426, 461-467, 472-513, 581-616, 693-709, figs. 17*).—Entomological contributions presented at the Sixth Congress of the International Society of Sugar Cane Technologists are: Sugarcane Pests in Florida, by J. W. Ingram, H. A. Jaynes, and R. N. Lobdell (pp. 89-98) (U. S. D. A. and Fla. Expt. Sta.); Rodents in Relation to Sugarcane Growing, by F. E. Garlough (pp. 98-105) (U. S. D. A.); The Field Rats and Their Control in Formosa, by S. Takano and T. Kondo (pp. 106-112); Biological Control of *Diatraea saccharalis* (Fabricius) in St. Lucia, B. W. I., by H. E. Box (pp. 223-240); Some Aspects of the Control of the Sugarcane Moth Borer *Diatraea saccharalis* F., by R. W. E. Tucker (pp. 240-243); The Introduction and Colonization of the Amazon Fly *Metagonistylum minense* Tns. in Puerto Rico, by K. A. Bartlett (pp. 243-245); Further Attempts to Establish *Likrophaga diatraea* (Townsend) and Other Sugarcane Borer Parasites in Louisiana and Florida, With Recoveries in 1936 and 1937, by H. A. Jaynes (pp. 245-258), and Introduction and Recoveries of Parasites of Sugarcane Insects in Continental United States, by T. E. Holloway (pp. 259-261) (all U. S. D. A.); Trend in Natural Parasitism of Sugarcane Borer (*Diatraea saccharalis* (F.)) by *Trichogramma* spp., by A. L. Dugas (pp. 361-367) (La. Sta.); *Trichogramma* Proves Itself in Sugarcane Borer Control, by E. G. Smyth (pp. 367-377); The Progress of Applied Entomology in Mauritius During the Years 1933 to 1934, With Reference to Insects of the Sugarcane, by W. F. Jepson and L. A. Moutia (pp. 377-382); The Introduction of Predatory Beetles Into Puerto Rico to Aid in the Control of the Yellow Cane Aphid *Sipha flava*, by K. A. Bartlett (pp. 383-385) (U. S. D. A.); An Attempt to Colonize *Hippodamia convergens*, by C. O. Eddy (pp. 385, 386) (La. Sta.); Some Phases of Biological Control Work Applicable to Sugarcane Insect Problems, by C. P. Clausen (pp. 421-426) (U. S. D. A.); Stem Galls of Sugarcane Induced With An Insect Extract, by J. P. Martin (pp. 461-467) (Hawaii. Sugar Planters' Sta.); Biology and Importance of the Sugarcane Rootstock Weevil *Anacetrinus subnudus* Buch. in Louisiana, by B. A. Osterberger and M. B. Christian (pp. 472-475) (La. Sta.); The Cell-Sap Concentration of Sugarcane Varieties in Relation to Their Resistance to the Attack of the White Leaf Louse, by M. Yamasaki and H. Arikado (pp. 475-479); A Summary of Investigations on the Sugarcane Beetle in Louisiana, by J. W. Ingram, E. K. Bynum, and W. A. Douglas (pp. 478-482), and Insect Vectors of Sugarcane Mosaic in Continental United States, by J. W. Ingram, W. E. Haley, and L. J. Charpentier (pp. 483-494) (both U. S. D. A.); Some Aspects of the Campaign Against the Moth Borer *Diatraea saccharalis* Fabr. in Antigua and St. Kitts, 1931-1938, by H. E. Box (pp. 493-513); Preliminary Report on Studies of Progenies of Sugarcane Crosses

for Susceptibility to Sugarcane Borer Injury in Louisiana, by R. Mathes, J. W. Ingram, and W. E. Haley (pp. 581-589) (U. S. D. A.); The Introductions of *Thoresia claripalpis* V. d. W. Into Cuba and Its Artificial Multiplication, by L. C. Scaramuzza (pp. 589-595); Quarantine Measures Against Insects Carried by Transpacific Airplanes, by C. E. Pemberton (pp. 595, 596) (Hawaii. Sugar Planters' Sta.); Sources of Infestation by the Sugarcane Borer and Trash Treatment for the Destruction of Overwintering Borers, by E. K. Bynum, W. E. Haley, and L. J. Charpentier (pp. 597-610), and Plant Quarantine Restrictions on the Entry of Sugarcane Into the United States, by E. R. Sasser (pp. 611-616) (both U. S. D. A.); Experiments With Insecticides in the Control of the Sugarcane Borer (*Diatraea saccharalis*) (Fab.), by L. O. Ellisor and J. W. Ingram (pp. 693-705) (La. Sta. and U. S. D. A.); and Sugar and Sugar Products in Insecticides, by C. O. Eddy (pp. 705-708) (La. Sta.).

[Contributions on fruit insects and their control] (*Ind. Hort. Soc. Trans.*, 1938, pp. 33-40, 67-71, 85-103, 104-107, 114-116, 129-133).—Contributions presented at the seventy-eighth annual meeting held at La Fayette in January 1939 include the following: Oriental Fruit Worm Control With Parasites, by J. J. Davis (pp. 33-35), and The Control of the Oriental Fruit Moth by Mechanical Means, by G. E. Marshall (pp. 37-40) (both Ind. Expt. Sta.); Sprays for Aphid Control, by G. S. L. Carpenter (pp. 67-70); The Effect of Recent Increase in Government Lead Tolerance on Spray Practice, by C. L. Burkholder (p. 85) (Ind. Sta.); Codling Moth Insecticide Investigations in 1938 at the Vincennes Laboratory, by L. F. Steiner, J. E. Fahey, and S. A. Summerland (pp. 86-99) (U. S. D. A.); Recent Studies and Trends in Codling Moth Control in Indiana, by G. E. Marshall (pp. 100-102) (Ind. Sta.); and Our Experience With Nicotine-Bentonite Spray, by S. W. Holmes (pp. 104-106).

Other contributions given are: Removal of Nicotine-Bentonite Spray Residues from Apples at Harvest, by J. E. Fahey, H. W. Rusk, L. F. Steiner, and R. F. Szama (pp. 114-116) (U. S. D. A.); and The Present Status of the Oriental Fruit Moth in Indiana, by G. E. Marshall (pp. 129-132), The Theory and Practice of First Brood Codling Moth Control, by C. L. Burkholder (pp. 132-134), Mr. Fruit Grower Versus Codling Moth, by J. J. Davis (pp. 134-139), and Lead and Arsenic Residues Resulting From Several Spray Schedules and Materials, La Fayette, 1937, by C. L. Burkholder, O. W. Ford, and D. L. Johnson (pp. 139-143) (all Ind. Sta.).

The insect problem in shelterbelt plantations, J. A. MUNRO (*North Dakota Sta. Bimo. Bul.*, 1 (1939), No. 6, pp. 3, 4).—Brief mention is made of borers and leaf-eating insects, the two groups of chief importance as enemies of the shelterbelt plantings of the Northern Great Plains area. The species concerned are the carpenter worm, particularly destructive in the older plantings of green ash and to a lesser extent the American elm and cottonwood, the ash borer, which sometimes causes appreciable injury to shelterbelt plantings of ash and lilac, the flatheaded apple tree borer, which with other borers attack upwards of 90 percent of newly transplanted stock, cankerworms, grasshoppers, and a hornworm (*Hyloicus chersis*).

202 common household pests of North America, H. HARTNACK (*Chicago: Hartnack Pub. Co.*, 1939, pp. 319, [figs. 268]).—A practical account.

House insulation and insect infestations, E. A. BACK. (U. S. D. A.). (*Ent. Soc. Wash. Proc.*, 41 (1939), No. 4, pp. 129-136, figs. 10).

Medical entomology, W. B. HERMS (*New York: Macmillan Co.*, 1939, 3. ed., rev., pp. XIX+582, figs. [197]).—This, the third edition of the work previously noted (E. S. R., 51, p. 356), appears under an abbreviated title, and is a completely rewritten edition.

A list of parasites recorded from the domestic and wild animals and birds of Cyprus, R. MOYLAN GAMBLES (*Cyprus Agr. Jour.*, 34 (1939), No. 1, pp. 29-32).

A study of the olfactory responses of insect parasites to the food plant of their host, W. H. THORPE and H. B. CAUDLE (*Parasitology*, 30 (1938), No. 4, pp. 523-528).

The chemical control of insect pests of animals, J. HENDRICK and W. MOORE (*Highland and Agr. Soc. Scot. Trans.*, 5. ser., 51 (1939), pp. 58-74).

The control of fleas and tropical rat mites, M. A. STEWART. (Univ. Calif.). (*Pests*, 7 (1939), No. 5, pp. 6, 7, 8).

[Contributions on insect control] (*Tenn. State Hort. Soc. Proc.*, 33 (1937), pp. 73-78, 84-88).—Contributions on insect control presented at the annual convention at Jackson in November 1937 include: Control of Tomato Fruit Worm by Use of Cottonseed Meal Containing 10 Percent Cryolite, by W. W. Stanley (pp. 73-77), Control of Tomato Fruit Worm, by W. W. Stanley and S. Marcovitch (pp. 77, 78), and Spray Residues and Human Health, by S. Marcovitch (pp. 84-88) (all Tenn. Expt. Sta.).

Entoma: A directory of insect pest control, edited by C. C. HAMILTON (*Plainfield, N. J.: Boise Ptg. Co.*, 1939, 3. ed., pp. [1]+170).—A revised edition of this directory (E. S. R., 78, p. 657).

Fly spray analysis (*Soap*, 14 (1938), No. 10, pp. 91, 93, 95).—An account is given of a systematic study made by the Pacific Coast Insecticide Association of certain acid methods for determining pyrethrins I and II in household insecticides.

Insecticide analysis: The determination of pyrethrins in pyrethrum products and of rotenone in derris and cube, J. J. T. GRAHAM. (U. S. D. A.). (*Soap*, 15 (1939), No. 2, pp. 97, 99, 101, 109).

Pyrethrum evaluation, M. S. LOWMAN and W. N. SULLIVAN. (U. S. D. A.). (*Soap*, 14 (1938), No. 11, pp. 89-91, 93, 119).—A report on the relation of the pyrethrin content of pyrethrum flowers to their toxicity to mosquito larvae.

Preparation of pyrethrins: Isolation of pyrethrin II, M. S. SCHECHTER and H. L. HALLER. (U. S. D. A.). (*Soap*, 14 (1938), No. 11, pp. 101, 103).—A report on the effect of aqueous extraction on the pyrethrin content of pyrethrum.

Methyl bromide used successfully to fumigate plants in soil beds, C. C. HAMILTON. (N. J. Expt. Stas.). (*Hort. Topics*, 3 (1939), No. [6], p. 11).—Experiments have shown that methyl bromide emulsions made by adding 50 cc. of methyl bromide to 250 cc. of wood alcohol and adding this to 3 gal. of water will kill grubs of the Asiatic beetle in azalea beds both in the greenhouse and outdoors. Examination made 7 days after treatment revealed that 100 percent of the Asiatic beetle larvae were either dead or completely disabled, the azalea plants having suffered no injury. The 3 gal. of emulsion thus prepared was applied with a sprinkling can to 50 sq. ft. of soil containing growing azalea plants.

The use of protective films of insecticide in the control of indoor insects, with special reference to *Plodia interpunctella* Hb. and *Ephestia elutella* Hb., C. PORTER (*Ann. Appl. Biol.*, 25 (1938), No. 4, pp. 836-854).—In a series of experiments and a field scale trial made of a film spraying method for the protection of stored goods from infestation by the tobacco moth and *P. interpunctella* reinfestation was prevented completely when the goods were efficiently sterilized before storage. "The procedure is to spray the interior of the warehouse and the cases stored in it with an insecticide consisting of a solution of 0.8 percent pyrethrins in a white oil, the constitution of which is given. The apparatus and method of spraying are described. Spraying should be started

some time before the moths are expected to emerge, in England about May 15, and should be continued twice a week throughout the period of moth emergence, which may continue until September 30."

Effect of arsenic and copper sprays on Navel oranges, R. H. MARLOTH and F. J. STORBERG (*Farming in So. Africa, 1½* (1939), No. 155, pp. 180, 181).—This report deals with the results obtained over a 4-yr. period as to the effect of the application of lead arsenate and copper carbonate sprays on the quality of Washington Navel orange fruits, as determined by the total soluble solids and acid contents of the juice. No evidence was obtained of any effect of lead arsenate on the total soluble solids in the fruit juice. Copper carbonate applied in five cover sprays at the total rate of 5 oz. per large tree showed no effect on either the total soluble solids or acid contents of the juice of fruit from sprayed trees. A slight earliness in coloring of the fruit sprayed with this material was observed. Chemical analyses made showed that the quantity of arsenic present in the fruit juice following cover sprayings with lead arsenate was negligible. No increase in the lead or copper content in the fruit juice above that normally found resulted from cover sprays of lead arsenate and copper carbonate."

It is pointed out that the insect pests of citrus in South Africa include the false codling moth *Argyroplotea leucotreta*, the Mediterranean fruitfly, the Natal fruitfly *Pterandrus rosa*, and the bollworm.

Winter spraying: Trees and shrubs, C. C. HAMILTON. (N. J. Expt. Stas.). (*Shade Tree, 12* (1939), No. 2, pp. [2-5]).

An investigation of the interrelationships of the vegetation, soils, and termites, J. M. MURRAY (*So. African Jour. Sci., 35* (1938), pp. 288-297, figs. 2).

Notes on Symphyla with descriptions of three new species of Symphylella from California, A. E. MICHELLBACHER. (Univ. Calif.). (*Pan-Pacific Ent., 15* (1939), No. 1, pp. 21-28, fig. 1).—Under the names *S. subterranea*, *S. cavigli*, and *S. capitata*, three members of the genus *Symphylella*, occurring in California, are described as new to science.

Psocids in dwellings, E. A. BACK. (U. S. D. A.). (*Pests, 7* (1939), No. 6, pp. 8, 9).

Grasshopper outbreaks in Missouri, G. D. JONES (*Missouri Sta. Bul. 406* (1939), pp. 52, figs. 12).—A review is given of the occurrences of grasshoppers in the Missouri area as known since 1817, together with 22 references to the literature consulted. Notes on the life history of the native grasshoppers of Missouri and observations made during recent outbreaks are briefly considered.

Vegetation types associated with plague "grasshoppers" in South Australia, H. G. ANDREWARTHA, J. DAVIDSON, and D. C. SWAN (*So. Austral. Dept. Agr. Bul. 333* (1938), pp. 47, pl. 1, figs. 73).

Field observations on the brown locust in an outbreak centre, C. J. B. SMIT (*Union So. Africa Dept. Agr. and Forestry, Sci. Bul. 190* (1939), pp. 145, figs. 34).—A detailed report of observations during the seasons 1935-36, 1936-37, and 1937-38 on the *solitaria* and *transiens congregans* phases of the brown locust *Locustana pardalina* (Walk.) in its natural environment. A list is given of 19 references to the literature.

The locust outbreak in Africa and western Asia in 1937, B. P. UVAROV and W. MILNTHORPE (*London: Econ. Advisory Council, Com. Locust Control, 1939, pp. 64, pls. 9*).—A further report on locust outbreaks (E. S. R., 80, p. 228).

The occurrence of the brown and red locust [*Locustana pardalina* and *Nomadacris septemfasciata*] in the Union during the seasons 1934-35 and 1935-36, C. DU PLESSIS (*Union So. Africa Dept. Agr. and Forestry, Sci. Bul. 164* (1937), pp. 17, figs. 9).

Control of mole crickets, J. R. WATSON. (Fla. Expt. Sta.). (*Citrus Indus*, 20 (1939), No. 5, p. 14).

Notes on the bionomics of roaches inhabiting houses, G. E. GOULD and H. O. DEAY. (Purdue Univ.). (*Ind. Acad. Sci. Proc.*, 53 (1937), pp. 281-284).

A synopsis of the American species of Chirothrips Haliday (Thysanoptera), F. ANDRE. (U. S. D. A.). (*Ent. Soc. Wash. Proc.*, 41 (1939), No. 6, pp. 192-204, figs. 10).

Five new species of Miridae from Texas (Hemiptera), H. G. JOHNSTON. (Tex. A. and M. Col.). (*Bul. Brooklyn Ent. Soc.*, 34 (1939), No. 2, pp. 129-133).—One species each of the genera *Atractotomus* and *Eustictus* and three species of the genus *Neoborus* are described as new to science.

The flugorina of Barro Colorado and other parts of Panama, Z. P. METCALF. (Univ. N. C.). (*Bul. Mus. Compar. Zool.*, 82 (1938), No. 5, pp. [1]+277-423, pls. 23).

The injury and spread in France of *Ceresa bubalus* F., the American buffalo treehopper enemy of cultivated crops [trans. title], A. BALACHOWSKY (*Rev. Pathol. Vég. et Ent. Agr. France*, 26 (1939), No. 1, pp. 39-61, figs. 8).—This membracid, which was first reported from Europe by Horwarth in 1931, having been discovered in Hungary, has since spread and is now of economic importance in southern France. A bibliography of 20 references is given.

The behavior of POJ 2878 sugar cane in relation to Fiji disease and transmission of the virus by nymphs of *Perkinsiella vastatrix*, G. O. OCEFFMIA and M. S. CELIXO (*Phytopathology*, 29 (1939), No. 6, pp. 512-517, fig. 1).—In transmission experiments it was found that in addition to adults of the leafhopper *P. vastatrix*, second, third, fourth, and fifth instar nymphs can transmit the virus of Fiji mosaic disease of sugarcane. It is pointed out that the nymphs that hatch from eggs laid by viruliferous leafhoppers do not carry the Fiji disease virus. The viruliferous adult *P. vastatrix* requires at least 24 hr. to elapse before it can transmit the disease.

Dormant and delayed dormant sprays for the control of the rosy apple aphids in Virginia, W. S. HUGH. (Va. Expt. Sta.). (*Va. State Hort. Assoc. Proc.*, 80 (1939), pp. 21-24).

Studies on aphides infesting the potato crop.—VII, Report on a survey of the aphid population of potatoes in selected districts of Scotland (July 23-August 6, 1936), W. M. DAVIES (*Ann. Appl. Biol.*, 26 (1939), No. 1, pp. 116-134, fig. 1).—In this further contribution (*E. S. R.*, 80, p. 73) the results of a survey of the green peach aphid, *Macrosiphum pisi* Koch, *Aphis rhamni* Boyer, and *Myzus pseudosolani* Theob. on potatoes in certain districts of Scotland are reported.

Transmission of sugarcane mosaic by aphids, H. D. TATE and S. R. VANDENBERG. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 59 (1939), No. 1, pp. 73-79).—In sugarcane mosaic transmission experiments in Puerto Rico, four species of aphids were used, namely, *Carolinata cyperi* Ainsl., the rusty plum aphid, *Sipha flava* (Forbes), and the corn leaf aphid. It was shown that *C. cyperi* can transmit mosaic from diseased to healthy sugarcane plants. Of 192 plants exposed to *C. cyperi* taken from diseased plants, 31.2 percent developed mosaic, as did 34.5 percent of 200 healthy plants exposed to infective corn leaf aphids. Field observations revealed the presence of *C. cyperi* on its host plant (*Cyperus rotundus*) in and around sugarcane fields in Puerto Rico in considerable abundance in certain periods of the year. In the transmission experiments the rusty plum aphid was shown to transmit mosaic from diseased to healthy sugarcane plants, thus confirming the evidence obtained by earlier investigators. Of 75 healthy sugarcane plants exposed to *S. flava* taken from diseased plants, none

developed mosaic. In most cases a considerably higher percentage of transmission resulted when young seedling plants were exposed to infective aphids than when plants grown from cuttings were employed.

Time of pea aphid treatment in relation to aphid populations and plant development in Wisconsin, H. F. WILSON and C. E. DIETER (*Canner*, 88 (1939), No. 23, pp. 18, 19, figs. 6).

Three new species of Aphididae (Homoptera), A. A. GRANOVSKY. (Minn. Expt. Sta.). (*Ent. Soc. Wash. Proc.*, 41 (1939), No. 5, pp. 143-154, figs. 17).—*Drepanosiphum oregonensis*, which feeds singly on the lower side of maple (*Acer macrophyllum*) leaves in Oregon; *Calaphis coloradensis*, common on western red birch (*Betula fontinalis*) and taken on *B. alba*, feeding on the lower side of the leaves and terminal shoots of young growth in Colorado and Utah; and *Mysocallis meridionalis*, which feeds on the lower side of leaves of several oaks, namely, water oak (*Quercus nigra*), white oak (*Q. alba*), red oak (*Q. rubra*), and willow oak (*Q. phellos*), in Texas, Georgia, and Mississippi, are described as new.

Entomological investigations on the leaf-curl disease of tobacco in Northern India.—III, The transmission of leaf-curl by white-fly *Bemisia gossypiperda* to tobacco, sann-hemp, and a new alternate host of the leaf-curl virus, H. S. PRUTHI and C. K. SAMUEL (*Indian Jour. Agr. Sci.*, 9 (1939), No. 2, pp. 223-275, pls. 4, fig. 1).

Spot treatment for red scale, M. B. PATTERSON (*Calif. Citrog.*, 24 (1939), No. 10, pp. 368, 369, fig. 1).—A description is given of the so-called spot treatment for red scale, which has proved economical and effective in the Corona district of California in handling resistant red scale where spotty conditions of infestation frequently are found.

Results of different methods of oil application for the control of scale insects on citrus, W. L. THOMPSON. (Fla. Expt. Sta.). (*Fla. State Hort. Soc. Proc.*, 51 (1938), pp. 109-114).

The opportunity for forestry practice in the control of gypsy moth in Massachusetts woodlands, C. E. BEHRE (*Jour. Forestry*, 37 (1939), No. 7, pp. 546-551, figs. 2).—The author concludes that, with the gypsy moth recognized as an established pest in New England, control efforts in Massachusetts woodlands should turn from measures aimed at eradication to the creation of forest conditions less favorable for serious outbreaks.

Some observations on the life history, habits, and control of the rice caseworm *Nymphula depunctalis* Guen., P. SISON (*Philippine Jour. Agr.*, 9 (1938), No. 3, pp. 273-301, pls. 4, fig. 1).—A report of studies of *N. depunctalis*, one of the most important rice pests in the Philippines, where it attacks the crop from July to November. Its life cycle from egg to egg, under laboratory conditions, varied from 21 to 37 days, with an average of about 27 days. A list is given of 14 references to the literature.

The cactus-feeding Phycitinae: A contribution toward a revision of the American pyralidoid moths of the family Phycitidae, C. HENNICH (*U. S. Natl. Mus. Proc.*, 86 (1939), No. 3053, pp. 331-413, pls. 29).—In this contribution on the cactus-feeding group of American pyralidoid moths 18 genera, 46 species, and 2 varieties are considered, of which 8 genera and 8 species are described as new to science.

The habitat, distribution, and dispersal of the psychid moth *Luffa ferchaultella* in England and Wales, R. S. McDONOGH (*Jour. Anim. Ecol.*, 8 (1939), No. 1, pp. 10-28, figs. 3).—Report is made of a study of *L. ferchaultella*, a small wingless moth with casebearing larvae that depend for food on the

algal-lichen flora of the trunks of trees. The larvae are carried by the wind to a distance of at least several miles.

Further notes on the fall cankerworm and its control by "solid-stream" spraying. R. E. BALCH (*Sci. Agr.*, 19 (1939), No. 7, pp. 411-423, figs. 4).—These notes relate to further investigations, particularly of the outbreak of the fall cankerworm on the large elms in Fredericton, New Brunswick (E. S. R., 80, p. 387), which has been completely controlled by spraying, although it continues in the woodlands of the St. John Valley. Additional notes are given on the bionomics of the species, and the methods of control by spraying are described.

It appears that the fall cankerworm may be a very serious pest of elm trees in a town if the trees are numerous and the ground beneath them is not more than 60-percent paved. "Complete control by spraying is possible on trees up to 100 ft. in height with a solid-stream sprayer which has a capacity of 400-lb. pressure and 50 U. S. gal. per minute. Calm weather is necessary, however. Pyrethrum powder, 0.8 percent pyrethrins, at the rate of 2 lb. per 100 Imperial gal. will give extremely satisfactory control if applied before the larvae reach the final stage. The addition of 5 lb. of arsenate of lead will insure practically 100-percent control if the spraying is thorough. This may be dispensed with, however, in moderate infestations. A sticker is not essential. Spraying is much cheaper and more efficient than banding."

The citrus rind borer and its control. C. E. GARCIA (*Philippine Jour. Agr.*, 10 (1939), No. 1, pp. 89-93, pls. 2).—A brief account of *Prays citri* Milliere, one of the most serious pests of the pummelo, sweet orange, lemon, lime, and several other varieties, including the wild citrus, and its control. It is one of the most serious pests of these fruits in the Philippines, India, Ceylon, and Malay.

Cryolite recommended for control of orange tortrix. A. M. BOYCE and C. O. PERKINS. (Calif. Citrus Expt. Sta.). (*Citrus Leaves*, 19 (1939), No. 5, pp. 5, 26).—The work of a representative committee is said to have shown that a dust mixture of cryolite applied at the rate of 0.5 lb. per mature tree can be safely used against the orange tortrix without exceeding the fluorine tolerance. "Without consideration of other insect problems, the most practical formula is cryolite 50 percent plus talc 50 percent. A dosage of 1 lb. of the dust mixture to the tree should be used. However, if sulfur dust is used in an insect control program, in which a treatment will be applied after about May 15, the cryolite may be incorporated with the sulfur dust. A generally useful formula is cryolite 40 percent plus sulfur 60 percent, used at a dosage of 1.25 lb. to the tree. This allows 0.5 lb. of cryolite and 0.75 lb. of sulfur per tree. If the treatment is applied at a time when more than 0.75 lb. of sulfur per tree is desirable, either the dosage per tree of the above formula should be increased or an appropriate formula used. However, regardless of the percentage of cryolite in the dust mixture, a dosage that would allow 0.5 lb. of cryolite per tree should be used. Only a well-established brand of cryolite should be considered."

Present recommendations for control of orange tortrix. A. M. BOYCE and C. O. PERKINS. (Calif. Citrus Expt. Sta.). (*Calif. Citron.*, 24 (1939), No. 8, pp. 278, 312).—A discussion of recommended control measures for the orange tortrix.

A field experiment on the control of the European corn borer (*Pyrausta nubilalis* Hubn.) by *Beauveria bassiana* Vuill.—H. G. BLALL, G. M. STRETT, and I. L. CONNERS (*Sci. Agr.*, 19 (1939), No. 8, pp. 531-534).—Work conducted in 1937 in continuation of that of the preceding year (E. S. R., 78, p. 823) has again shown that the time of application of the fungus *B. bassiana* is of the greatest importance when used against the European corn borer and worthy of further investigation. In both 1936 and 1937 a control of 60 or 70 percent was effected.

The development of a second generation of the European corn borer (*Pyrausta nubilalis* Hbn.) in Indiana, G. A. FIGHT. (Ind. Expt. Sta.). (*Ind. Acad. Sci. Proc.*, 54 (1938), pp. 211-215, fig. 1).—Evidence is presented that a second generation of the European corn borer occurs in Indiana, although there has been little tendency on the part of such generation to select host plants other than corn for oviposition. The importance of the appearance of the second brood in Indiana is pointed out.

The use of baits in oriental fruit moth control, M. L. BOBB. (Va. Expt. Sta.). (*Ud. State Hort. Soc. Proc.*, 41 (1939), pp. 15-20).

Ethylene dichloride emulsion for the control of the peach borer, O. I. SNAPP. (U. S. D. A., Ill. and N. Y. State Expt. Stus et al.). (*Tenn. State Hort. Soc. Proc.*, 34 (1938), pp. 82-86).

Baits and bait traps in codling moth control, M. L. BOBB, A. M. WOODSIDE, and R. N. JEFFERSON (*Virginia Sta. Bul.* 320 (1939), pp. 19, figs. 7).—Studies conducted in Virginia over a period of 4 yr. in Albemarle and Augusta Counties during the season of 1935 to 1938, inclusive, and in Patrick County in 1938 are reported. A bait that consisted of 1 part of stock syrup to 20 parts of water to which 1 cc. of anethol per quart was added proved to be the most constantly attractive material tested during the 4-yr. period. "Generally the catch of moths was increased to a slight extent during the summer months by the addition of a small amount of sodium benzoate to the bait mixture. Few moths were caught in old, rusty traps. The largest catch of moths was made in new, unpainted bait traps, and the second largest in bait traps painted with aluminum paint. The position of the bait trap in the tree was an important factor in determining its efficiency. When three bait containers were suspended at three different heights in an apple tree, the trap in the top of the tree captured more moths than the other two traps combined. The use of 1/4-inch-mesh wire screens over the tops of the traps had little effect on the catch of moths, but there was a slightly higher percentage of moths captured in traps without covers. Of the captured moths examined during 1938, approximately 60 percent were females and less than 5 percent of these had deposited their full quota of eggs. Bands on trees in unbaited blocks of apple trees caught approximately six times as many codling moth larvae as similar bands on trees in the baited block of trees in the same orchard. Under usual weather conditions, bait traps should be suspended in apple trees about May 1 in central Virginia and about April 20 in southern Virginia."

[Codling moth control work] (*Ind. Hort. Soc. Trans.*, 1937, pp. 84, 85, 88-107).—Contributions presented at the annual meeting of the Indiana Horticultural Society at La Fayette, January 1938, on codling moth include: Some Results of Bait Trap Experiments in 1937, by L. F. Steiner and S. A. Summerland (pp. 84, 85), Per Cent Larvicidal Efficiency and Spray Deposits in Relation to Growth, Rainfall, and Timing of Cover Sprays on Jonathan, by L. F. Steiner, J. E. Fahey, R. F. Sazama, and H. W. Rusk (pp. 88, 89), and Large Scale Tests of Tank-Mix Nicotine-Bentonite-Soyoil in 1937, by L. F. Steiner and R. F. Sazama (pp. 89-91) (all U. S. D. A.).

Check list of the Lepidoptera of boreal America, superfamilies Sphingoidae, Saturnioidae, and Bombycoidea of the families Syntomidae and Arctiidae, W. BARNES and F. H. BENJAMIN (*Bul. South. Calif. Acad. Sci.*, 26 (1927), No. 2, pp. 35-50).—A continuation of this check list (*E. S. R.*, 55, p. 662).

The mosquitoes of the Southeastern States, W. V. KING, G. H. BRADLEY, and T. E. McNEEL (*U. S. Dept. Agr., Misc. Pub.* 336 (1939), pp. 91, pls. 6, figs. 26).—The introductory part of this work consists of an account of the genera and species found in the southeastern United States, summarized in table form; the literature on mosquitoes; their general characteristics and habits; collec-

tion and preservation of material; and identification. Methods of mosquito control are then dealt with (pp. 14-28), followed by notes on the genera, 11 in number, and the species (pp. 28-57), and synoptic tables for the identification of the mosquitoes of this area, both adults and fourth-stage larvae. A list of 122 references to the literature cited and an index of genera and species are included.

Habits of *Aedes thibaulti* Dyar and Knab. (Diptera, Culicidae), W. R. HORSFALL (Univ. Ark.). (*Jour. Kans. Ent. Soc.*, 12 (1939), No. 2, pp. 70, 71).

Ground beetles predatory on the eggs of *Aedes* mosquitoes, H. H. STAGE and W. W. YATES. (U. S. D. A.). (*Ent. Soc. Wash. Proc.*, 41 (1939), No. 6, pp. 204-206).

Notes on some parasites and predators of blackflies (Simuliidae, Diptera), C. R. TWINN (*Canad. Ent.*, 71 (1939), No. 5, pp. 101-105).—These notes relate to certain of the natural enemies of blackflies, some of which may be of value in developing biological control measures.

Biology, morphology, and anatomy of aphidophagous syrphid larvae, M. L. BHATIA (*Parasitology*, 31 (1939), No. 1, pp. 78-129, figs. 75).—This contribution reports upon the biology, morphology, and anatomy of seven species of syrphid larvae found in Cambridge that live on aphids, namely, *Syrphus luniger* Meig., *S. balteatus* DeG., *S. ribesii* Linne, *Oatobomba pyrustris* Linne, *Sphaerophoria flavicauda* Zett., *S. scripta* Linne, and *Platychirus scutatus* Meig. A list of 36 references to the literature is included.

On the changes in chemical composition associated with larval development in the sheep blowfly, R. C. RAINEY (*Ann. Appl. Biol.*, 25 (1938), No. 4, pp. 822-835, figs. 5).—The disappearance of fat typical of cleidoic eggs is the most marked change in composition found by the author during embryonic development of the sheep blowfly *Lucilia sericata*.

Studies of the physiology and toxicology of blowflies.—I, The development of a synthetic medium for aseptic cultivation of larvae of *Lucilia cuprina*, F. G. LENNOX (*Austral. Council Sci. and Indus. Res. Pam.* 90 (1939), pp. 24, pl. 1, figs. 8).—A description is given of a technic for the cultivation of larvae of *L. cuprina* in small, flat-walled bottles. "Growth is recorded, without opening the cultures, by photographing the larvae at a standard magnification. The evolution of a basal medium for the aseptic cultivation of the larvae is also described. It contains only yeast and sodium chloride, in addition to agar, which is added to give a suitable gel consistency. Although larvae reach full size on this medium, growth is more rapid on an enriched medium containing fresh egg white in place of the agar. The pH limits for growth on synthetic media are wide and vary from below 4 to beyond 8 or 10, the exact upper limit depending on the composition of the medium."

A note on rearing houseflies, C. EAGLESON and R. BENKE. (U. S. D. A.). (*Soap*, 14 (1938), No. 11, pp. 109, 119, fig. 1).

The generative organs of the blowfly *Calliphora erythrocephala* L., with special reference to their musculature and movements, G. S. GRAHAM-SMITH (*Parasitology*, 30 (1938), No. 4, pp. 441-476, figs. 16).

New genera and species of muscoid Diptera, H. J. REINHARD. (Tex. Expt. Sta.). (*Bul. Brooklyn Ent. Soc.*, 34 (1939), No. 2, pp. 61-74).—The genera *Clastoneuriopsis* and *Philocalia* are erected and new species are described as follows: *Emblemasoma* and *Sarcophaga* two species, and *Opsotheresia*, *Clastoneuriopsis*, *Philocalia*, and *Siphoclytia* one species each.

Breeding houseflies, E. G. THOMSEN and M. H. DONEY (*Soap*, 14 (1938), No. 10, pp. 89, 90, 101, fig. 1).—A description is given of a simplified and more convenient method of rearing and handling flies for use in experimental work.

Observation on white grub pupation, P. O. RITCHER. (Ky. Expt. Sta.). (*Jour. Kans. Ent. Soc.*, 12 (1939), No. 2, pp. 64-69).—Data on the pupation depths of 320 white grubs belonging to 8 species of Kentucky May beetles are presented. "It was found that *Phyllophaga hirticula* larvae usually pupate deep in the soil while larvae of *P. inversa* pupate at shallow depths. *P. futilis*, [*P.*] *fusca*, and [*P.*] *bipartita* usually seek intermediate depths for pupation. Certain factors such as soil structure, soil drainage, and soil moisture may affect the pupation levels, but they do not appear to change the relative positions of the various species. Differences in latitude appear to make little difference in the depth of pupation for a given species, other factors being equal."

New and little known *Phyllophaga* from Texas (Scarabaeidae, Coleoptera), H. J. REINHARD. (Tex. Expt. Sta.). (*Jour. Kans. Ent. Soc.*, 12 (1939), No. 2, pp. 47-63, figs. 13).—This contribution includes descriptions of seven species and four subspecies of *Phyllophaga*, new to science, together with notes on four little known species previously described.

Descriptions of the three larval instars of the Japanese beetle (*Popillia japonica* Newm.) (Coleoptera, Scarabaeidae), A. G. BÖVING. (U. S. D. A.). (*Ent. Soc. Wash. Proc.*, 41 (1939), No. 6, pp. 183-191, figs. 24).

The probable future distribution of the Japanese beetle in North America, H. FOX (*Jour. N. Y. Ent. Soc.*, 47 (1939), No. 2, pp. 105-123).

Revision of the beetles of the melolonthine subgenus *Phytalus* of the United States, L. W. SAYLOR (*U. S. Natl. Mus. Proc.*, 86 (1939), No. 3048, pp. 157-167, pls. 2).—While engaged in this revision of beetles of the subgenus *Phytalus*, seven in number, the economic status of the majority of which species is little known, the author observed *P. pallida* Horn doing a good deal of damage in Arizona by eating the foliage of rose bushes, young fruit trees, and walnut trees, often stripping them.

Pathogenicity of *Beauveria bassiana* (Bals.) Vuill. on Colorado potato beetle larvae, M. I. TIMONIN (*Canad. Jour. Res.*, 17 (1939), No. 4, Sect. D, pp. 103-107, figs. 5).—It was found that *B. bassiana*, isolated from infected larvae of the Colorado potato beetle, is pathogenic in this host. Experiments conducted indicate that some of the infected larvae "may pass through the larval stage, but owing to further mycelial growth finally succumbed in the pupal stage. The fungus does not attack the eggs, but infected young larvae were found dying on the fourth day after hatching, when the eggs had been dusted with *B. bassiana* spores. The mycelial growth on the infected larvae is more rapid in the soil than above ground."

The elm leaf beetle, C. W. COLLINS (*U. S. Dept. Agr. Leaflet* 184 (1939), pp. [1]-6, figs. 3).—A practical account.

Four wireworms found in bluegrass sod, H. H. JEWETT (*Kentucky Sta. Bul.* 392 (1939), pp. 107-118, figs. 18).—Technical descriptions are given of four species of wireworms that live in bluegrass sod in Kentucky, some of which become pests of crops that follow sod in rotations. The four species, which have been found most frequently injuring tobacco plants, and are here described in detail, are: *Aeolus dorsalis*, *Oonoderes auritus*, *O. bellus*, and *O. lividus*.

Description of the larva of *Ludius divaricatus* Lec., H. H. JEWETT. (Ky. Expt. Sta.). (*Canad. Ent.*, 71 (1939), No. 5, pp. 105-108, figs. 2).

The occurrence of *Tribolium destructor* Uytt. in seeds in England, C. POTTER (*Ent. Mo. Mag.*, 3, ser., 25 (1939), No. 293, pp. 114, 115).—The beetle *T. destructor*, introduced into England from Italy, is said to have become a pest of stored products, with indications that it may prove serious.

Notes on Coleoptera found in raisin storages, H. C. DONOHUE. (U. S. D. A.). (*Ent. Soc. Wash. Proc.*, 41 (1939), No. 5, pp. 154-162).—Notes are given

on 32 insect forms found in raisin storages in Fresno and Tulare Counties of the San Joaquin Valley of California.

Studies on the coconut palm beetle *Oryctes rhinoceros* Linn. in South India. M. C. CHERIAN and K. P. ANANTANARAYANAN (*Indian Jour. Agr. Sci.*, 9 (1939), No. 3, pp. 541-559, pl. 1).—An account of the biology of *O. rhinoceros* in South India, with notes on control measures.

The giant palm borer (Coleoptera Bostrichidae), an economic pest in lower California, A. E. MICHELbacher and E. ROSS. (Univ. Calif.). (*Calif. Dept. Agr. Bul.*, 28 (1939), No. 2, pp. 166-169, figs. 3).—The giant palm borer *Dinapate wrighti* Horn, of which the Washington palm is the host and which may be almost completely destroyed by the borings of the larvae, is said to have a very limited distribution, appearing in Palm Canyon, Calif., and at Catavina, Lower California (Mexico), some 300 miles to the south.

Cryptorhynchus lapathi L. in relation to the watermark disease of the cricket-bat willow, E. M. CALLAN (*Ann. Appl. Biol.*, 26 (1939), No. 1, pp. 155-157).—Although the poplar and willow borer has been found occasionally attacking the bat willow (*Salix alba caerulea* Smith) it has not yet been associated with the watermark disease in the field.

The white fringed beetle [*Naupactus leucoloma* Boh.] a serious threat to southern agriculture, J. R. WATSON. (Fla. Expt. Sta.). (*Fla. State Hort. Soc. Proc.*, 51 (1938), pp. 127-129).

The species of *Pantomorus* of America north of Mexico, L. L. BUCHANAN (*U. S. Dept. Agr., Misc. Pub.* 341 (1939), pp. 40, figs. 5).—Report is made of a taxonomic study of a group of scarred-snout beetles, which includes species of considerable importance, as Fuller's rose beetle and the recently introduced South American white-fringed beetle *Naupactus leucoloma* Boh. In the region north of Mexico the genus has been found represented by 4 subgenera, 11 species, and 3 varieties. Those described as new are the 2 subgenera *Graphognathus* (type, *N. leucoloma*) and *Atrichonotus* (type, *N. taeniatus* Berg), the 2 species *peregrinus* (type locality, Gulfport, Miss.) and *planifolius* (type locality, Pueblo, Colo.), and 1 variety *elegans caximius* (type locality, San Diego, Tex.). The new synonymy is as follows: *taeniatus* Berg (= *texanus* Pierce 1911), *elegans elegans* (Horn) (= *metallicus* Pierce), *candidus* (Horn) (= *nebraskensis* Pierce), and *texanellus* new name (= *texanus* Pierce 1913). Two previously "lost" generic names belonging to the *Pantomorus* complex (*Adomopactus* Jekel 1876 and *Pantopactus* Jekel 1876) are noted. Parthenogenesis has been demonstrated for *P. leucoloma* and *P. godmani* and probably occurs also in *P. peregrinus*, *P. taeniatus*, *P. tessellatus*, and *P. pallidus*. Of these 6 species *P. leucoloma* and *P. taeniatus* are known to be native to South America and the other 4 are probably also South American. The gamogenetic species and varieties which comprise the subgenus *Phacepholis* are all indigenous to North America.

The plum curculio in Tennessee, S. MARCOVITCH and W. W. STANLEY. (Tenn. Expt. Sta.). (*Tenn. State Hort. Soc. Proc.*, 54 (1938), pp. 86-88).

Studies on American foul brood of bees, III, IV, H. L. A. TARR (*Ann. Appl. Biol.*, 25 (1938), No. 4, pp. 307-321, pls. 3).—A continuation of this contribution (*U. S. R.*, 80, p. 664) from the Rothamsted Experimental Station, presented in two parts.

III. The resistance of individual larvae to inoculation with the endospores of *Bacillus larreae*.—The author reports having failed to produce American foul-brood by direct inoculation of eggs, or larvae from the time of hatching to that just subsequent to sealing, by placing "from 0.001 to 0.005 cc. of aqueous suspensions of washed spores of *B. larreae*, obtained from natural sources, in their cells. With this method of oral inoculation, larvae are rarely removed by the bees and mature normally when each receive from a few thousand

to over 45×10^6 spores of *B. larvae*. Feeding individual larvae with unwashed spores of *B. larvae*, or with portions of crushed larvae recently affected with American foulbrood, does not cause the disease. Methods of inoculation, in which the adult bees are allowed access to relatively dilute suspensions of *B. larvae* spores, form a satisfactory means of initiating American foulbrood in colonies of bees. It is inferred that adult bees play an important part in carrying American foulbrood in the colony, and the possible role of the adult bee as 'insect vector' of American foulbrood is considered."

IV. *On the attempted cultivation of Bacillus pluton, the susceptibility of individual larvae to inoculation with this organism, and its localization within its host.*—It was found that *B. pluton* "will not grow on the chorioallantoic membrane of the developing chicken embryo or on embryo brei medium made from minced embryos. European foulbrood is a purely intestinal infection of the bee larva, the causal organism being localized in the food mass within the peritrophic membrane. Young larvae are readily infected with European foulbrood by mixing relatively small numbers of *B. pluton* organisms, obtained from recently affected larvae, with the brood food surrounding them."

The control of meat ants (*Iridomyrmex detectus* Sm.), T. GREAVES (*Jour. Council Sci. and Indus. Res. [Austral.]*, 12 (1939), No. 2, pp. 109-114).

On some larval stages of two species of Ichneumonidae, *Bassus tetragonus* Thunb. and *Homocidus fissorius* Grav., parasitizing *Sphaerophoria flavicauda* Zett. (Diptera, Syrphidae), M. L. BHATIA (*Parasitology*, 30 (1938), No. 4, pp. 502-510, figs. 11).—This contribution deals mainly with the larvae of *B. tetragonus*.

Two new chalcidoid parasites of the linseed midge *Dasyneura lini* Barnes, I, II (*Indian Jour. Agr. Sci.*, 9 (1939), No. 3, pp. 531-539, pl. 1).—Part 1 of this contribution (pp. 531-535), which is by T. Ahmad, deals with the biology and morphology of *Systasis dasyneurae* Mani; part 2 (pp. 535-539), by M. S. Mani, consists of a description of its parasites, namely, *S. dasyneurae* n. sp. and *Errikotomorpha taskhiri*, n. g., n. sp.

The phytophagous chalcidoid *Eurytoma samsonovi* Vas., a serious pest of apricot and some other fruits in India, H. S. PRUTHI and H. N. BATRA (*Indian Jour. Agr. Sci.*, 9 (1939), No. 2, pp. 277-283, pl. 1).—Observations on the biology of *E. samsonovi*, which attacks apricot, peach, etc., in the North-West Frontier Province of India, are reported.

The control of the woolly aphid by *Aphelinus mali*, L. J. DUMBLETON and F. J. JEFFREYS (*New Zeal. Jour. Sci. and Technol.*, 20 (1938), No. 3A, pp. 183A-190A, fig. 1).—Records of the percentage of parasitism in the field by *A. mali* are presented, and factors influencing the extent to which the aphid is controlled by the parasite are considered.

The life history of *Allotropa utilis* Mues., a hymenopterous parasite of the orchard mealybug [*Phenacoccus aceris* Sign.] in Nova Scotia, F. C. GILLIATT (*Canad. Ent.*, 71 (1939), No. 7, pp. 160-163, fig. 1).—A report of observations of the biology of the parasite above noted. Its parasitism seems to fluctuate according to the abundance of the host, varying from 50 to 66 percent in orchards when the host is abundant and from 2 to 15 percent where the mealybug is not numerous.

A new mealybug parasite (Hymenoptera: Scelionidae), C. F. W. MUESEBECK. (U. S. D. A.). (*Canad. Ent.*, 71 (1939), No. 7, pp. 158-160, fig. 1).—Under the name *Allotropa utilis*, a description is given of a scelionid parasite of the orchard mealybug *Phenacoccus aceris* (Sign.) in Nova Scotia.

Epimegastigmus (*Megastigmus*) *brevivalvus* Girault: A parasite of the citrus gall wasp *Eurytoma fellis* Girault, with notes on several other species of hymenopterous gall inhabitants, N. S. NOBLE (*N. S. Wales Dept.*

Agr., Sci. Bul. 65 (1938), pp. 46, figs. 18).—Accounts of the morphology and biology of *Epimegastigmus breviculrus* (pp. 5-30), *E. trisulcus* Gir. (pp. 31-34), and *Epibootania novvitta* Gir. (pp. 35-40) are followed by a discussion of the relative abundance of the various species of parasites of *Eurytoma fellis* in the Grafton District, New South Wales. The accounts include a list of 27 references to the literature cited.

Further notes on *Trichogramma semblidis*, G. SALT (*Parasitology*, 30 (1938), No. 4, pp. 511-522, figs. 3).—The author has found several "behavioristic and physiological differences [to] distinguish the two species *T. semblidis* and *T. evanescens*. There are no true intermediates between the two forms of the male *T. semblidis*, but intermediate types are simulated by degenerate individuals of small size produced by starvation. Among 1,740 males reared from eggs of *Sialis* and 1,847 reared from eggs of moths, there were only 19 exceptions to the rule that the apterous form emerges from the former and the winged form from the latter. The ability of *T. semblidis* to produce its apterous male can remain latent through as many as 64 generations reared on *Sitotroga* and yet find its full expression immediately when the parasite is reared on *Sialis*. Several other species of Neuroptera have been parasitized, but *S. lutaria* remains the only known host that regularly elicits the apterous form. *T. semblidis* is capable of arrhenotokous parthenogenesis. The statement that the species includes thelytokous strains requires corroboration."

A new reared Meteorus from Tasmania (Hymenoptera: Braconidae). C. F. W. MUESEBECK. (U. S. D. A.). (*Ent. Soc. Wash. Proc.*, 41 (1939), No. 5, pp. 172, 173).—Under the name *M. dumbletoni* a description is given of a new braconid parasite reared from *Tortrix postrittana* Walker in Hobart, Tasmania.

A species of gall-mite (Eriophyidae) injurious to tomato, A. M. MASSEE (*Ann. and Mag. Nat. Hist.*, 11, ser., 3 (1939), No. 18, pp. 617-619, fig. 1).—A gall mite that produces whitish pilose areas on the stems and young fruitlets of the tomato plant in Morocco, the damage by which is somewhat similar to that produced by *Phyllocoptes lycopersici* Massee (*E. S. R.*, 78, p. 673), is described as new under the name *Eriophyes lycopersici*. Its distribution is said to include all the tomato-growing districts extending for 120 miles along the seacoast of Morocco.

The relation of mites to animals and plants in South Africa, R. F. LAWRENCE (*So. African Jour. Sci.*, 35 (1938), pp. 332-338).

Eriophyid studies, III, H. H. KEIFER (*Calif. Dept. Agr. Bul.*, 28 (1939), No. 2, pp. 144-162, figs. 14).—A continuation of the earlier studies (*E. S. R.*, 81, p. 254) in which 15 species are described as new.

Ornithodoros talaje on the California mainland, T. H. G. AITKEN. (Univ. Calif.). (*Pan-Pacific Ent.*, 15 (1939), No. 1, pp. 12, 13).—Report is made of the collection of specimens of *O. talaje* in the Mojave Desert near Palmdale, San Bernardino County, Calif. This is believed to be the first actual record of its collection on the California mainland. Reference is also made to a later collection in Contra Costa County at an altitude of 2,000 ft.

The development of *Moniezia expansa* in the intermediate host, H. W. STUNKARD (*Parasitology*, 30 (1938), No. 4, pp. 491-501, pl. 1).—It was found that when eggs of *M. expansa* are fed to galumnid mites, "the onchospheres emerge in the intestine and migrate to the body cavity. Here they undergo metamorphosis and develop into cysticeroids. The dissection of mites, at various intervals after exposure, has yielded a successive series of developmental stages. Protocols of the experiments and photographs of living larvae are presented. These results demonstrate that mites serve as intermediate hosts of *Moniezia* and probably also of other anophlocephaline cestodes."

ANIMAL PRODUCTION

[Experiments with livestock in Mississippi] (*Miss. Farm Res. [Mississippi Sta.]*, 1 (1938), Nos. 1, pp. 4, 5, fig. 1; 2, pp. 5, 7, 8; 3, p. 6; 2 (1939), Nos. 1, p. 5; 2, pp. 4, 8; 3, p. 3; 4, pp. 3, 7; 5, pp. 2, 6).—Progress reports of numerous lines of investigation are presented in brief articles as follows: Vol. 1, No. 1, Green Crops for Laying Hens Mean More Eggs and Less Feed, by G. R. Sipe, and Twenty-five Dollar Cows Produce Spring Calves Worth as Much, by E. W. Sheets; No. 2, Rye Grass, Mustard, and Bermuda in Year-Round Poultry Grazing, by G. R. Sipe; Home Grown Feed and Green Forage Essential in Pork Production, by P. G. Bedenbaugh and H. H. Leveck; and Feeding Practices for the Work Mules, by R. H. Means; No. 3, Cottonseed Meal for Hogs Being Tested, by P. G. Bedenbaugh and H. H. Leveck; Vol. 2, No. 1, Efficient Production and Usage of Roughages a Major Farm Problem, by E. W. Sheets; No. 2, Good Pasture Most Profitable Feed Source for Dairy Cattle, by J. S. Moore; and Choice Spring Lambs From Good Pasture, by H. H. Leveck; No. 3, Mineral Deficiencies in Livestock New Approach to Old Problem, by E. W. Sheets and V. R. Berliner; No. 4, Dairy Calves Showing Symptoms of Vitamin A Deficiency Respond to Treatment With Cod Liver Oil, by W. C. Cowser; The Effect of Ration on Colt Production—Feeding Breeding Sires, by F. E. Cowart and V. R. Berliner; and Successive Grazing Crops for Producing Home Supply of Pork on Small Farms, by E. W. Sheets; No. 5, Cottonseed Meal for Broilers, by H. D. Polk, and Corriedale Rams With Native Ewes Mean Increased Wool Production, by H. H. Leveck.

[Livestock investigations in New Mexico] (*New Mexico Sta. Rpt. 1938*, pp. 32, 33, 35-41, 85-87, fig. 1).—Reports of progress (E. S. R., 79, p. 55) are presented for studies on the natural revegetation of ranges under controlled and limited grazing and the carrying capacities of ranges, the rate of increase or decrease of plague on grazed and protected areas, the calcium and inorganic phosphorus content in the blood of range cattle, the composition of range grasses and browse gathered at varying stages of maturity, cottonseed meal as a concentrate for fattening yearling steers, the amount of cottonseed meal required to supplement hegari fodder and hegari grain in lamb-fattening rations, and battery cages v. pen management of laying pullets.

Commercial feeding stuffs, H. R. KRAYBILL ET AL. (*Indiana Sta. Cir. 249* (1939), pp. 39, fig. 1).—This condensed report of the commercial feed inspection for 1938 (E. S. R., 79, p. 522) covers 3,180 samples of feeding stuffs examined during the year with an indication of the number failing to meet the standard specifications. The average and range of analyses are given for 112 samples of canned dog foods examined. Definitions of a large number of feeding stuffs as approved by the Association of American Feed Control Officials are also presented.

Caking mature steers on pasture, R. H. MEANS (*Miss. Farm Res. [Mississippi Sta.]*, 2 (1939), No. 5, pp. 3, 4).—Three trials were conducted to determine whether cottonseed meal or cake could be fed profitably to mature steers grazing on good pasture, the level at which cottonseed cake or meal might be fed most economically, and the most profitable length of the grazing and feeding period. Grade Jersey or "Yellow Hammer" steers were used in the first trial, first-cross steers from native cows by beef-type bulls in the second, and good grade beef-type steers in the third trial. In each case the three groups of steers received 0, 2.5, and 5 lb. of cottonseed meal per head daily, respectively. In each instance the feeding of cottonseed meal proved to be unprofitable. In the first two trials steers receiving cottonseed meal made only slightly greater average daily gains than those receiving no supplement, with practically no difference between the

groups receiving the two levels of meal. In the third trial the average daily gains were considerably greatest for the supplemented lots, but the increased market value of these steers was more than offset by the cost of the supplement.

Spring vs. fall calving, R. H. MEANS (*Miss. Farm Res. [Mississippi Sta.]*, 2 (1939), No. 5, pp. 5, 6, figs. 5).—A 3-yr. comparison was made of the returns secured from fall-born v. spring-born beef calves, the observations extending over the time of breeding the dams through the feeding and slaughtering of the calves. The advantages derived from spring calves were a higher percentage calf crop, slightly less feed required over the entire growth and finishing period, the calves finishing at about 42 days younger age, and less trouble from screwworm infestation. The advantages derived from fall calves were approximately 2 mo. longer suckling period with the dams in better condition at weaning time, a price advantage when calves were marketed as feeders at weaning time, approximately 30 days shorter finishing period, and a higher average price for Good and Choice cattle during the market period for finished fall-born calves. The results appeared to warrant consideration of the production of fall-born as well as spring-born calves.

Tankage, a protein supplement for fattening beef calves, J. W. WILSON and T. WRIGHT (*South Dakota Sta. Bul.* 329 (1939), pp. 15, figs. 6).—Results are summarized for three separate feeding trials comparing the rate and economy of gain of fattening beef calves on a basal ration of shelled corn and alfalfa hay, when (1) no protein supplement, (2) linseed meal, (3) cottonseed meal, (4) dry-rendered tankage, and (5) a 1:1 mixture of linseed meal and tankage were added to the diet. The average daily gains per calf were 2.23, 2.37, 2.39, 2.21, and 2.35 lb. in lots 1 to 5, respectively. The tankage proved less palatable than linseed or cottonseed meal, the steers consuming only about one-half as much of the former supplement as of the latter two. The mixed supplement was intermediate in palatability. Calves in the cottonseed meal group showed the best finish and commanded the highest average selling price, closely followed by the mixed supplement and linseed meal groups, while the tankage-fed lot only slightly excelled the no-supplement group in degree of finish. The mixed animal and vegetable protein supplement did not prove superior to either of the straight vegetable supplements. In two trials in which a lot fed shelled corn, wild hay, and tankage were included, the calves consumed about 1 lb. of tankage per head daily, or approximately twice as much as a comparable group receiving alfalfa hay.

Breeding ewe lambs, D. L. HIRM (*North Dakota Sta. Bimo. Bul.*, 1 (1939), No. 6, pp. 7, 8).—In a further report of this line of investigation (El. S. R., 75, p. 91), results of a second trial comparing groups of purebred Shropshire, Hampshire, and Southdown ewes bred as lambs and as yearlings essentially agreed with those of the former trial which involved the same comparison with grade ewes. At 35 mo. of age the yearling-bred ewes averaged 13.7 lb. heavier than the lamb-bred ewes, but at 48 mo. of age differences in weight were not significant. A comparison of the performance of the two groups at 2-year-olds showed that the lamb-bred ewes raised a higher percentage of lambs than the yearling-bred ewes. Lamb-bred Hampshires dropped lighter lambs but weaned heavier ones than the yearling-bred group, while yearling-bred Shropshires dropped and weaned heavier lambs. The effect of age of breeding on the percentage of twins dropped varied between breeds and also within breeds from year to year so that the results on this point are inconclusive. In general, it is recommended that purebred ewe lambs of the above breeds should not be exposed to breeding before they are 10 mo. of age and, further, that ewe lambs should not be bred unless the best of care can be given them.

Economical production of pork demonstrated in two experiments (*Miss. Farm Res. [Mississippi Sta.]*, 2 (1939), No. 7, pp. 1, 8).—A summary of pig-feeding trials at the main station and the Delta Substation gives evidence that through the use of properly balanced rations consisting largely of home-grown feeding stuffs, pastures, and good management pork can be produced at from 4 to 6 ct. per pound at prevailing feed prices.

In the report by H. H. Leveck a ration containing corn and soybeans (85:15) when fed to pigs on green pasture gave relatively low-cost gains and resulted in a satisfactory quality of pork as compared with a corn and tankage ration.

In the report by W. P. McFadden a ration of corn and cottonseed meal (70:30) when hand-fed to pigs on alfalfa pasture gave relatively economical and satisfactory gains. Under these conditions the addition of 5 percent of tankage to the concentrate ration was not justified. Less satisfactory results were obtained by feeding the corn and cottonseed meal ration to pigs on wheat or Sudan grass pasture. When cottonseed meal is fed to pigs on such pasture a ration of corn, tankage, and cottonseed meal (85:7.5:7.5) is recommended.

[Poultry investigations in Rhode Island] (*Rhode Island Sta. Rpt.* [1938], pp. 56, 57).—Progress results are noted on a study of the effect of varying levels of alfalfa leaf meal on hatchability, egg yolk color, and livability of adult birds.

The significance of body weight in breeding for egg production, F. A. HAYS (*Massachusetts Sta. Bul.* 364 (1939), pp. 16, figs. 4).—Employing the data obtained on 2,283 Rhode Island Red pullets, the relationship between body weight and various characters related to egg production was determined. The pullets showed the highest rate of gain during the first month of laying, with a continued gradual gain until mature weight was attained at 11 or 12 mo. of age. Considerable parallelism was observed between the mean monthly body weight and mean monthly egg weight, also between monthly body weight and monthly egg production. The highest level of egg production occurred in March and April when body weight was at a maximum. Satisfactory winter egg weight and egg production were not obtained unless pullets averaged 1 lb. gain in weight during the laying year. Increases greater than 1 lb. in weight were accompanied by heavier winter eggs. There was a consistent decline in mortality in the laying house as the weight of pullets at the time of housing increased. It is concluded that body weight offers a valuable guide to the poultry breeder, particularly from the standpoint of egg size and extent of laying house mortality.

Egg production and livability of pullets as affected by management, D. C. KENNARD and V. D. CHAMBERLIN. (*Ohio Expt. Sta.*). (*Poultry Sci.*, 18 (1939), No. 4, pp. 318-322).—Five systems of management of chicks and growing pullets, with representatives from each group kept in floor pens and in laying cages during the laying year, were compared in this experiment. None of the management practices proved more than partially effective in reducing the mortality of pullet layers. Chicks having access to isolated range after 2 weeks proved superior, both in egg production and livability, to those confined to wire sun porches from 8 to 10 weeks before being placed on range. Egg production in floor pens averaged highest for those pullets reared on the isolated range. In practically all cases livability and total egg production of pullet layers in laying batteries were better than similarly raised pullets kept in floor pens. Pullets brooded and reared in batteries generally proved unsatisfactory when placed in floor pens during the laying year, whereas they were generally satisfactory when continued in batteries during the laying period.

Breed variations in egg characters, G. O. HALL. (*Cornell Univ.*). (*Poultry Sci.*, 18 (1939), No. 4, pp. 282-287).—A statistical analysis of various egg char-

acters for the White Wyandotte, Barred Plymouth Rock, Rhode Island Red, and Single Comb White Leghorn revealed no significant breed differences in egg weight, weight of yolk, weight of total white, height of albumin, yolk index, percentage of total yolk, and percentage of total white. Compared with eggs of other breeds and with the average of all breeds, the Barred Plymouth Rocks were lower in weight of shell, percentage of shell, and weight and percentage of inner thin white, but had a greater amount and higher percentage of thick white. Similarly, eggs from Rhode Island Reds had a significantly higher percentage of inner thin white and eggs from White Leghorns a significantly higher percentage of outer thin white. The White Wyandottes differed significantly from the Rhode Island Reds and White Leghorns and from the mean of all breeds in observed score of condition of firm albumin. Meat spots were more numerous in eggs of Plymouth Rocks and Rhode Island Reds.

Effect of varying levels of wheat bran on age at sexual maturity, L. W. TAYLOR and I. M. LERNER. (Univ. Calif.). (*Poultry Sci.*, 18 (1939), No. 4, pp. 323-326).—Groups of Single Comb White Leghorn chicks were reared on well-balanced rations containing 0, 15, and 25 percent of red wheat bran, respectively. The inclusion of either the 15 or 25 percent level of bran resulted in more rapid growth of the chicks, earlier sexual maturity of the pullets, and, as a direct result of the latter, lower egg weight at the beginning of the laying period. Such changes in the ration did not affect annual egg production, March egg weight, nor the extent and kind of pathology occurring among pullets.

The calcium and phosphorus contents of chickens of various ages, J. R. HAAG. (Oreg. Expt. Sta.). (*Poultry Sci.*, 18 (1939), No. 4, pp. 279-281).—Data are presented on the live weight and the calcium and phosphorus contents of the bodies of chickens at 0, 2, 4, 8, 12, 16, and 20 weeks of age. The calcium:phosphorus ratio gradually widened with advancing age, ranging from approximately 1.3 in day-old chicks to about 1.7 at 20 weeks. Comments regarding the usefulness and limitations of these data are included.

The effect of high temperature on the blood calcium of the laying hen, R. M. CONRAD. (Kans. Expt. Sta.). (*Poultry Sci.*, 18 (1939), No. 4, pp. 327-329).—In a series of experiments in which hens were maintained at various constant levels of temperature and relative humidity, it was found that high temperature materially affected the blood calcium of the hens. An increase in temperature from 70° F. to about 90° caused a decrease of from 25 to 30 percent in the blood calcium level. Such changes were not due apparently to decreased calcium intake at the higher temperature. The effect of high temperature on the thickness of eggshell probably can be attributed directly to the decreased calcium-carrying capacity of the blood.

Effect of single cereal grains upon the hatchability of eggs and subsequent growth of chicks, V. D. CALL and H. L. WILCKE. (Iowa Expt. Sta.). (*Poultry Sci.*, 18 (1939), No. 4, pp. 303-317).—Four groups of yearling hens were fed and managed under similar conditions except for the source of grain in the ration. Groups 1 to 4 received corn, wheat, oats, and a complex grain mixture (control), respectively. Mortality was high in all lots of breeders, ranging from 14.3 percent in the oat lot to 46.4 percent in the corn lot. Wheat as the only grain produced diarrhea in the adult birds which apparently contributed to high mortality. Egg production was highest for the mixed grain group, closely followed by the corn-fed lot, while the oat-fed lot was consistently lower and the wheat group less than half that of the control lot. Fertility was not significantly different on the various rations. Hatchability was best from the wheat-fed group, closely followed by the oat lot, while the other two

groups were somewhat lower and about equal. Chicks from hens fed oats or wheat were more vigorous than those from corn-fed hens. However, the grain ration of the parental stock had little apparent effect on subsequent growth rate of chicks.

The efficiency of carotene as supplied by alfalfa meal in meeting the vitamin A requirements of laying hens, J. K. WILLIAMS, C. E. LAMPMAN, and D. W. BOLIN. (Idaho Expt. Sta.). (*Poultry Sci.*, 18 (1939), No. 4, pp. 268-275).—A series of experiments was conducted in which laying hens received a basal diet low in vitamin A but adequate in other known dietary factors supplemented with alfalfa meal at such rates as to provide 0.1, 0.2, 0.25, 0.3, 0.4, and 0.5 mg. of carotene per bird daily. Birds receiving 0.2 mg. of carotene per day, equivalent to 333 U. S. P. units or 238 Sherman-Munsell units of vitamin A, maintained good body weight and fair egg production with good hatchability and failed to develop deficiency lesions in the throat, whereas 0.1 mg. per bird daily was definitely insufficient to prevent deficiency symptoms. Increasing the alfalfa meal intake to provide 0.5 mg. of carotene per bird daily slightly increased egg production but otherwise did not seem to benefit the hen. The higher level resulted in a higher vitamin A potency of the eggs, better livability of the chicks, and a greater storage of vitamin A in the livers of the hens.

Further studies on the riboflavin requirements of the chicken, C. H. HUNT, A. R. WINTER, and R. M. ВЕТНКЕ. (Ohio Expt. Sta.). (*Poultry Sci.*, 18 (1939), No. 4, pp. 330-336).—In one experiment involving only laying hens and in a second involving chicks from day old to 40 weeks of age, groups of birds were fed (1) a basal diet of corn, wheat, wheat bran, Argentine casein, steamed bonemeal, oystershells, salt, and cod-liver oil; (2) basal diet plus 5 percent of alfalfa leaf meal; (3) basal diet plus 10 percent of alfalfa leaf meal; (4) basal diet plus 5 percent of dried skim milk; (5) basal diet plus 10 percent of dried skim milk; and (6) basal diet plus 5 percent each of alfalfa meal and dried skim milk. These rations supplied 0.3, 1.5, 1.9, 1.6, 2.3, and 2.2 μ g. of riboflavin per gram of ration, respectively. The amount of feed consumed per hen increased as the riboflavin content of the ration increased. The riboflavin content of eggs varied directly with that in the hen's ration. Eggs of highest riboflavin content gave highest hatchability, and chicks from such eggs showed greatest livability when subjected to a riboflavin-deficient diet. Chicks required approximately from 190 to 200 μ g. of riboflavin per 100 gm. of ration to attain maximum growth from 1 to 12 weeks of age, while from 220 to 230 μ g. were required in laying rations to give good hatchability of eggs. It appeared that somewhat less riboflavin was required for good egg production than for maximum hatchability.

A curative method for the assay of vitamin D with chicks, J. S. CARVER, V. HEIMAN, and J. W. COOK. (Wash. Expt. Sta.). (*Poultry Sci.*, 18 (1939), No. 4, pp. 288-294, figs. 5).—The technic described consists essentially in depleting day-old sexed chicks for from 8 to 10 days on a vitamin D-deficient, low-mineral ration, and then feeding the vitamin D ration to be assayed for a 24-day period. The interpretation of the assay can be made on the basis of the growth response, the degree of healing of the ribia, or the percentage of ash in the ribia. By projecting onto a straight line of best fit either of these criteria over the negative control, the vitamin D unitage may be determined by interpolation.

The limit of accuracy of the A. O. A. C. chick assay for vitamin D, B. L. OSER (*Jour. Assoc. Off. Agr. Chem.*, 22 (1939), No. 2, pp. 445-449).—This discussion is based on a critical analysis of data submitted by 13 collaborators in the 1937 study of the A. O. A. C. chick assay for vitamin D. In the opinion

of the author, the minimum significant difference in bone ash value between assay groups should be twice the standard error, e. g., between two groups of 10 chicks each, two times 1.866 or 2.73 percent.

Egg deterioration due to ingestion by hens of malvaceous materials, F. W. LORENZ. (Univ. Calif.). (*Poultry Sci.*, 18 (1939), No. 4, pp. 295-300, fig. 1).—In a study of factors responsible for olive-yolk and pink-egg types of egg deterioration, nine groups of birds received supplements of (1) petroleum ether extract of raw cottonseed, equivalent to 5 percent cottonseed; (2) purified gossypol, 0.35 gm. per bird fed by capsule in six doses of from 0.05 to 0.06 gm. each; (3) mother liquor (tar) from gossypol preparation, equivalent to 15 percent cottonseed; (4) completely extracted cottonseed, 5 percent of the ration; (5) raw decorticated cottonseed, 5 percent; (6) petroleum ether extract of *Malva parviflora* seeds, equivalent to 10 percent raw seeds; (7) ethyl ether extract of the above-extracted seeds, 10 percent equivalent; (8) completely extracted *M. parviflora* seeds, 10 percent; and (9) young green *M. parviflora* leaves ad libitum. Two distinct substances were found to be present in cottonseed or cottonseed meal. Gossypol gave the yolk an olive-green color and a gelatinous consistency, while the other substance, which is either identical or closely associated with the substance responsible for the Halphen reaction, caused an abnormal enlargement of the yolk and a reddish color of yolk and albumin to develop in storage. Eggs from hens fed cottonseed developed a combination of these abnormalities. The Halphen substance was contained in other members of the plant family Malvaceae, and eggs from hens fed such plants developed only the second group of defects.

Fishy flavor in turkey meat caused by feeding menhaden fish meal, R. L. BRYANT and G. T. STEVENSON (*Virginia Sta. Bul.* 321 (1939), pp. 7).—Four groups of Bronze turkey poulters were fed rations containing 20 percent of flame-dried menhaden fish meal, 20 percent of steam-dried fish meal, 20 percent of meat scrap, and a combination of 10 percent each of fish meal and meat scrap, respectively, to 21 weeks of age, at which time all the fish meal in the rations was replaced by an equivalent amount of meat scrap. Representative birds from each group were killed, roasted, and scored for flavor at 21 weeks of age and at 2-week intervals thereafter until all traces of fishy flavor were eliminated from the cooked carcasses. Fishy flavor was detected in the roasted carcasses of turkeys receiving 10 percent or more of fish meal. Fishy flavor was eliminated within 4 weeks after the 10-percent level of fish meal feeding was discontinued and within 8 weeks after the 20-percent level was discontinued. The drippings had a more pronounced fishy flavor than did the meat, and male birds exhibited a slightly stronger fishy flavor than females. There was no marked difference in intensity of fishy flavor between the lots receiving the flame-dried and steam-dried meals.

Sulfured soil for poultry yards, M. W. EMMER. (Fla. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 94 (1939), No. 4, pp. 409, 410).—Preliminary studies gave evidence that heavy applications of commercial flour sulfur to poultry yards on which chickens are constantly confined proved an effective way of eliminating or greatly reducing various types of intestinal parasites.

DAIRY FARMING—DAIRYING

Timothy hay compared with alfalfa hay as a feed for dairy cows: Supplemental factors influencing the milk-producing value of alfalfa hay and timothy hay in feeding dairy cows, C. W. HOLDAWAY, W. B. EHLETT, J. F. EHLETT, and A. D. PRATT (*Virginia Sta. Tech. Bul.* 65 (1939), pp. 39).—The results of a series of experiments, extending over a period of 10 yr. and in

part previously noted (E. S. R., 68, p. 662), are summarized. The grain mixtures supplementing these hays were so adjusted as to provide equal levels of protein intake on the two rations, equal quantities of both hay and grain being fed to the two groups of animals during the test periods. The nutrients in the alfalfa hay rations proved slightly more digestible than those in the timothy hay rations. The addition of minerals with or without yeast did not affect the digestibility of the nutrients. The unsupplemented timothy ration produced an average of 87.5 percent and when supplemented with minerals 90.7 percent as much 4-percent milk as the alfalfa rations. The addition of dicalcium phosphate and calcium carbonate improved the efficiency of the timothy ration, and the addition of 10 gm. of yeast per cow daily to the above ration further improved its efficiency. The addition of bonemeal plus 100 gm. of yeast per cow daily materially decreased the amount of total digestible nutrients required from the timothy ration per unit of 4-percent milk produced. The milk production on the supplemented timothy ration compared more favorably with that on the alfalfa ration during the fourth to tenth months of lactation than during the first 3 mo. of the milking period, but on the average the milk production was in direct proportion to the total digestible nutrient intake within a 1-percent range. Thus it appeared that timothy hay of good quality will give efficient results as a roughage in the dairy cow's ration if the supplementary grain ration is properly balanced to supply the deficiencies in protein and minerals of the timothy hay.

A comparison of alfalfa silages prepared by the A. I. V. and molasses methods, D. M. HEGSTED, F. W. QUACKENBUSH, W. H. PETERSON, G. BOHSTEDT, I. W. RUPPEL, and W. A. KING. (Wis. Expt. Sta.). (*Jour. Dairy Sci.*, 22 (1939), No. 7, pp. 489-500, figs. 2).—Continuing this line of investigation (E. S. R., 78, p. 240), alfalfa silages prepared by the A. I. V. and molasses methods were compared both on the basis of chemical analyses and the quantity and quality of milk produced during feeding trials. Alfalfa containing from 20 to 25 percent of dry matter was well preserved by either method. The protein and carotene were somewhat better preserved by the A. I. V. method, although there was no pronounced difference in the lots. No significant differences in milk production were obtained when rations containing A. I. V. or molasses alfalfa silage or corn silage plus linseed meal were fed. The carotene and vitamin A contents of the butterfat produced on either of the alfalfa silages were relatively high. The milks from the three above lots were approximately equal in growth-promoting properties when fed to rats. The molasses silage appeared equal to the A. I. V. silage and was considered more suitable for general farm use.

Inadequacy of a whole milk ration for dairy calves as manifested in changes of blood composition and in other physiological disorders, G. H. WISE, W. E. PETERSEN, and T. W. GULLIKSON. (Minn. Expt. Sta.). (*Jour. Dairy Sci.*, 22 (1939), No. 7, pp. 559-572, figs. 8).—Twelve normal dairy calves were confined to a diet consisting solely of whole milk from birth. The calves varied widely in their responses to the diet, both in rate of growth and abnormalities developed. One calf died at 55 days of age, while at the other extreme one was maintained on the diet for 324 days before being removed from the experiment. The following abnormalities were observed among the calves at various times—general unthrifty appearance, anorexia, cachexia, dyspnea, occasional nervousness and tetany, rachitic condition, dysphagia, and digestive disturbances. Blood analyses revealed high but variable blood sugar values, extremes in fat of plasma with generally high values, a decrease in hemoglobin, a gradual downward trend in plasma magnesium, occasional cases of hypophosphoremia, and rarely cases of hypocalcemia. Post mortems of calves dying on

experiment revealed hypertrophied livers with evidence of fatty degeneration, gastritis, enteritis, and nephritis.

Value of various vitamins and inorganic salts for overcoming symptoms manifested in calves restricted to a whole milk ration, G. H. WISE, T. W. GULLICKSON, and W. E. PETERSEN. (Minn. Expt. Sta.). (*Jour. Dairy Sci.*, 22 (1939), No. 7, pp. 573-582, figs. 3).—Seven calves from the above experiment were removed from the sole milk diet at various ages and stages of malnutrition and placed on supplemented whole milk diets. Nearly all of the recognizable symptoms of the syndrome developed on the sole milk ration were temporarily remedied by supplying milk with ferric chloride, cupric sulfate, magnesium carbonate, and cod-liver oil. The adequacy of this supplemented diet was not demonstrated beyond the stage of advanced gestation. A depraved and erratic appetite persisted in calves on the supplemented diet which may have been due to a dietary deficiency or to the physical nature of the ration. Other possible factors relating to this syndrome are discussed.

The determination of blood plasma carotene in the bovine using a photoelectric colorimeter, L. A. MOORE. (Mich. Expt. Sta.). (*Jour. Dairy Sci.*, 22 (1939), No. 7, pp. 501-511).—A method is described for a simple phase separation of carotene from bovine blood and measuring the density of the extract by the use of the photoelectric colorimeter, thus permitting rapid determination of the concentration of carotene per unit of blood plasma by direct comparison of the galvanometer reading with a table of standard values. When petroleum ether with a boiling point of from 73° to 76° C. was used as the solvent and extraction carried out at from 10° to 12°, the epiphase gave true carotene values. Other precautions to be followed are outlined. Plasma stored at 2° showed no loss of carotene over a period of 3 weeks.

Effect of pasture upon the carotene content of blood plasma of the bovine, L. A. MOORE. (Mich. Expt. Sta.). (*Jour. Dairy Sci.*, 22 (1939), No. 7, pp. 513-519).—Blood samples from dairy heifers and from cows in various stages of lactation were taken for carotene analysis shortly before and after the cows were turned on pasture in the spring. Marked breed differences under similar conditions of feeding were observed. The breeds ranked in increasing order of plasma carotene as follows: Brown Swiss, Holstein, Ayrshire, Jersey, and Guernsey, with little difference between the first three. Heifers within a breed had a definitely lower plasma carotene value than producing cows under both winter and pasture conditions. The increase in plasma carotene values after the cows were turned on pasture was marked and showed a steady increase for a considerable period. Cows producing the larger amount of milk within a breed generally showed a greater increase in plasma carotene content. Such increases were evident within 15 hr. after green feed was ingested.

Milk goat improvement (New Mexico Sta. Rpt. 1938, pp. 59-61).—The effect of outbreeding and inbreeding on purebred Toggenburg goats is briefly summarized.

The influence of three methods of cleaning the cream separator and cream storage temperature on the keeping quality of cream, W. J. CAULFIELD and W. H. MARTIN. (Kans. Expt. Sta.). (*Jour. Dairy Sci.*, 22 (1939), No. 7, pp. 583-589, fig. 1).—In a comparison made of the quality of cream, that from an unwashed separator decreased to second grade when held at 60° F. more quickly than cream cleaned by either the conventional method or the Rogers method (E. S. R., 77, pp. 242). Storage temperature was found to exert a greater influence on keeping quality and the rate of acid development and proteolytic decomposition of cream than did the method of cleaning the separator. All samples changed from first to second grade in a short time when held at 80°.

The Rogers method of cleaning gave essentially as good results as the more laborious conventional method, but immersion of tinned steel or iron separator parts showed some dark discoloration after 2 weeks submersion in the trisodium phosphate-sodium chromate solution at from 85° to 92°.

Preliminary observations on the treatment of parchment paper with sodium or calcium propionate, H. MACY and J. C. OLSON. (Minn. Expt. Sta.). (*Jour. Dairy Sci.*, 22 (1939), No. 7, pp. 527-534, figs. 2).—Both salted and unsalted butters artificially contaminated with mold spores were wrapped in parchment paper which had been soaked either in sterile distilled water or in 8, 16, and 20 percent solutions of sodium or calcium propionate. After storage at 50° F. at high humidity for from 11 to 12 weeks the mold development was found to be markedly inhibited in those butters wrapped in the treated parchment, particularly those treated with the higher concentrations. The degree of inhibition was markedly greater in the salted butter.

Study of physical and chemical properties of the adsorption "membrane" around the fat globules in cream.—I, The effect of the adsorption "membrane" of synthetic creams on curd tension of cow's milk, N. P. TARASSUK and L. S. PALMER. (Minn. Expt. Sta.). (*Jour. Dairy Sci.*, 22 (1939), No. 7, pp. 543-558).—A series of synthetic creams was prepared by emulsifying pure butterfat in aqueous sols of dried whey, skim milk powder, calcium caseinate, gelatin, and tissue fibrinogen. These synthetic creams were dispersed in normal milk plasma to give remade milks, these were separated to give remade creams, and remade buttermilks were prepared by churning the remade creams. The addition of rennet to the buttermilk from the dried whey cream either resulted in no clotting or in the formation of a very soft fragile curd, and buttermilks from the gelatin and calcium caseinate creams showed no visible coagulation on the addition of rennet. The addition of relatively large concentrations of calcium chloride to the above creams appreciably restored their curd tension values, but the cause of this phenomenon was shown to be more deep-seated than the simple addition of calcium. The fat globule adsorption membrane from the tissue fibrinogen cream had no effect and that from the dried skim milk cream only a slight effect towards reducing the curd tension of the buttermilk. The phenomenon of low curd tension or noncoagulation with rennet in these remade buttermilks was accompanied by considerably lower pH and lower surface tension of the buttermilks. Such failures to clot on the addition of rennet is attributable to the liberation of certain fatty acids which are adsorbed by the calcium caseinate. Curd tension is not seriously affected by butterfat hydrolysis except when an unnatural emulsifying agent is substituted for the natural fat globule adsorption membrane of cow's milk.

The use of steapsin in the manufacture of blue cheese, S. T. COULTER and W. B. COMBS. (Minn. Expt. Sta.). (*Jour. Dairy Sci.*, 22 (1939), No. 7, pp. 521-535).—In an effort to increase the rate of flavor development in Roquefort-type cheese by hastening fat hydrolysis, commercial steapsin was added to the cheese curd at the rate of 1 gm. per 100 lb. of milk. Approximately the same degree of flavor development was secured in the treated cheese in 5 mo. as was obtained in 12 mo. in normal cheese. The steapsin cheese was accepted by the trade, but was scored by competent judges as having a characteristic bitter flavor. Cheeses receiving steapsin but not inoculated with mold became rancid and developed none of the typical blue cheese flavor, showing that to obtain the characteristic flavor *Penicillium roqueforti* must be present and active.

Comparisons of the inactivation of phosphatase enzyme and the killing of *Escherichia-Aerobacter* organisms as criteria of satisfactory pasteuriza-

tion of ice cream mix, F. E. NELSON, W. J. CAULFIELD, and W. H. MARTIN. (Kans. Expt. Sta.). (*Jour. Dairy Sci.*, 22 (1939), No. 7, pp. 535-541).—Continuing this line of investigation (E. S. R., 81, p. 569), it was found that in a typical ice cream mix the milk enzyme phosphatase was more resistant to heat than the more heat-resistant strains of bacteria in the *Escherichia-Aerobacter* group. It is concluded that the presence of *Escherichia-Aerobacter* organisms in the ice cream mix or in ice cream which is negative to the phosphatase test is indicative of contamination during or following pasteurization.

Controlling oxidized flavors, A. C. MAACK and P. H. TRACY. (Univ. Ill.). (*Ice Cream Trade Jour.*, 35 (1939), No. 3, pp. 32, 34).—A further report of research previously noted (E. S. R., 79, p. 102).

VETERINARY MEDICINE

[Diseases of farm animals in Mississippi] (*Miss. Farm Res. [Mississippi Sta.]*, 1 (1938), No. 3, p. 8; 2 (1939), No. 4, pp. 7, 8).—Brief articles are included as follows: Vol. 1, No. 3, Blackhead Loss in Turkeys Prevented by Tobacco Dust in Ration, by G. R. Sipe; Vol. 2, No. 4, For Protection Against Chicken Pox Vaccinate Chicks Early, by G. R. Sipe, and Stomach Worms, the Most Serious Menace to Southern Sheep, Yield to Treatment With Copper Sulphate, by H. H. Leveck.

[Work with animal diseases by the Rhode Island Station] (*Rhode Island Sta. Rpt.* [1938], pp. 57-60).—The work reported upon (E. S. R., 79, p. 535) relates to infectious coryza, with reference to studies of *Haemophilus gallinarum* and *H. influenzae*; infectious bronchitis; the use of iodine in treating gapeworm infection of pheasants; and autopsy examinations for the determination of diseases in fowls.

[Contributions on animal pathology and bacteriology] (*Jour. Bact.*, 38 (1939), No. 1, pp. 109, 112, 113, 114).—Among the abstracts of contributions presented at the meeting of local branches of the Society of American Bacteriologists in May 1939 are: Studies on a Presumably Nonpathogenic, Acid-fast Microorganism Frequently Present in the Tonsillar Tissue of Swine, by A. G. Karlson and W. H. Feldman (p. 109); and Modification of Distemper Virus by Animal Passage, by R. G. Green (p. 112), Natural Distemper in Grey Foxes, by C. A. Evans and R. G. Green (p. 113), and Nonfatal Infection with *Pasteurella tularensis* in the Snowshoe Hare, by J. F. Bell and R. G. Green (p. 114) (all Univ. Minn.).

[Contributions on animal parasitology] (In *Raboty po gel'mintologii (Papers on helminthology)*, edited by R. É. S. SHULTS (SCHULZ) and M. P. GNYEDINOV (GNYEDINA). Moskva: All-Union Lenin Acad. Agr. Sci., 1937, pp. 5-8, 23-44, 55-65, 69-80, 89-104, 126-128, 155-179, 183-214, 226-230, 245-252, 296-304, 328-347, 388-402, 408-411, 418-428, 433-439, 454-462, 467-482, 491-504, 508-511, 550-564, 586-609, 615-636, 640-662, 713-724, 734-743, 758-762, 792-794, figs. 165).—Among the contributions (for the most part in Russian) in this volume, published in commemoration of the thirtieth anniversary of the work of K. I. Skrzabin (K. J. Skrzabin) and the fifteenth anniversary of the All-Union Institute of Helminthology, are the following: On the Nutrition of the Nematode *Ascaridia lineata* (Schneider), by J. E. Ackert (pp. 5-8) (Kans. Expt. Sta.); A Comparison of the Anthelmintic Efficacy of Tetrachlorethylene and the "Sprehn-Capsules" Against Ascariidosis and Uncinariidosis of Silver Foxes, by D. N. Antipin (pp. 23-28, Eng. abs. pp. 27, 28); Some Drugs Used in the Control of Ascariids in Pigeons [trans. title], by E. A. R. F. Baudet (pp. 29-36, Russ. abs. pp. 35, 36); Pathologic Anatomy and Pathogenesis of Dictyocaulosis of the

Horse, by G. I. A. (G. J.) Belkin (pp. 37-44); The Nematodes of the Genus *Synthetocaulus* Parasitic in Sheep of Alma-Ata Territory, Kazakhstan, by S. N. Boev (Boyer) (pp. 55-62); *Echinoparyphium syrdariense* [n. sp.], a New Trematode of the Fowl, by T. El. Burdelev (pp. 63-65); A Revised Classification of the Nematoda, by B. G. Chitwood (pp. 69-80, Russ. abs. p. 80). A Review of the Genus *Oxyuris*, With a Morphological Study of *O. petrovi* Skrjabin 1929, Recently Discovered in Galliform Birds of the Northern United States, by E. B. Cram (pp. 89-93, Russ. abs. p. 98), Observations on the Biological and Morphological Relationships of *Dispharynx spiralis* in Bird Hosts, by E. Cu villier (pp. 99-104, Russ. abs. p. 104), and *Protostrongylus rushi*, a New Lungworm From the Mountain Sheep (*Ovis canadensis*), by G. Dikmans (pp. 126-128, Russ. abs. p. 128) (all U. S. D. A.); The Control of Strongyloidosis of Cattle, Sheep, Pig, and Horse, by V. S. Ershov (Ershoff) (pp. 155-159); The Life Cycle of Strongyloides, by E. C. Faust (pp. 160-166, Russ. abs. pp. 165, 166); Helminthofauna of Geese and Ducks in Western Siberia in Connection With the Problem of Natural Reservoirs for the Purpose of Bird Breeding, by A. V. Fedushin (Fedyushin) (pp. 167-177); Parasitic Worms of the Horses of Azerbaijan, by A. D. Gaibov (pp. 178, 179); Methods of Isolating the Eggs and Larvae of Helminths From the Grass of the Pastures, by M. P. Gnedina (pp. 183-188); Some Remarks on Suitable Terms to Describe Nematodes or Other Animals Which Feed on Decomposing Organic Matter, by T. Goodey (pp. 189, 190); A Study of Helminthofauna of Domestic Geese of Omsk and Chelyabinsk Regions, by I. P. Gorshkov (pp. 191-202); A Comparison of Methods for the Detection of Eggs of Swine Metastrongyles, by O. K. Gorchunova (Gorchunova) (pp. 203-206); A Comparison of the Lung Lesions Produced in Laboratory Animals by *Ascaris lumbricoides* of Swine, by G. L. Graham (pp. 207-214, Russ. abs. p. 214); The International Control of Parasites, by M. C. Hall (pp. 226-230, Russ. abs. p. 230) (U. S. D. A.); A Study of the Anthelmintic Efficacy of Oil of Terebentine and Carbon Bisulphide Used Against Ascarides and Strongylids of Horses, by S. V. Ivanitskii (Ivanitzky) and I. A. G. (J. G.) Krasnov (pp. 245-252) Helminthofauna of Mongolian Sheep and Goats, by A. V. Kopyrin (pp. 296-301); A Study of Treatment of the Dictyocaulosis of Horses, by N. S. Kulikov and I. B. (J. B.) Tamarin (pp. 302-304); On the Distribution of the Encysted Stage of Certain Cestodes, by E. Linton (pp. 328-332, Russ. abs. p. 332) (Univ. Pa.); Parafilariosis of Horses in the Territories of the Lower Volga, by L. A. Losev (Lossev), I. P. Erokhin, and A. F. Nikanorov (pp. 333-345); An Attempt of Treating the Crenosomatosis of Silver Foxes, by A. P. Lubimova (Lubimova) (pp. 346, 347); Anatomy and Morphology of the Strongyloides-Species of Domestic Animals, by S. A. Malygin (Malignin) (pp. 388-395); A Method for Calculating the Eggs Contained in the Body of Helminths, by O. I. Miretskii (O. J. Miretsky) (pp. 396, 397); Sparrows as Agent Distributing Helminthic Infections Among Domestic Animals, by A. A. Mozgovoi (Mosgovoy) (pp. 398-402); Helminths of Horses Found in the Voronezh Region, by B. Moskalev (Moskaleff) (pp. 408-411); A Study of the Biology of *Moniezia expansa*, by N. S. Murashkinfseev and I. I. (J. J.) Malevich (pp. 418-426); On the Resistance of Larval Echinococci Against Some Physical and Chemical Agents, by A. F. Nosik (Nossik) (pp. 427, 428); Methods of Vital Differential Diagnosis of Infestation of Ruminants by Strongylata, by I. V. Orlov (Orloff) (pp. 433-439); The Helminthofauna of Domestic Animals of Mordovian Autonomous Kuibyshev, and Orenburg Districts, by M. A. Palimpsestov (pp. 454-458); Tapeworms of Sheep in Leningrad Region, by L. G. (L. S.) Panova (pp. 459-462); The Treatment of Dictyocaulosis of Sheep, by A. I. A. (A. J.) Pervakov (pp. 467, 468); A Synopsis of the Helminth Parasites of Domestic Animals of Brazil [trans.

title], by C. Pinto and J. Lins de Almeida (pp. 469-482, Russ. abs. p. 482); The Interrelation Between the Infestation by Ascarids and Bacterial Infections in Experimental Conditions, by V. P. Pod'apol'skaja (Podyapolskaya) and N. P. Dedova (pp. 491-496); A New Nematode of Cattle, *Ostertagia kolchida* n. sp., by Z. G. Popova (pp. 497-499); A New Trematode Species, *Paramphistomum (Oculiorchis) skrjabini* From the Rumen of Cattle and Buffaloes, by K. A. Popova (pp. 500-504); Vital Differential Diagnosis of Horse Strongylosis, Delafondiosis, Alfortiosis, Triodontophorosis, and Trichonematosis, by A. M. Petrov and V. G. Gagarin (pp. 508-528); The Diagnosis and Treatment of Hymenolepidosis (*Hymenolepis lanreolata*) of Geese, by V. A. Potemkina (pp. 529-541); Trichostrongylids From Abomasum of Reindeers, by E. P. Pushmenkov (pp. 550-559); Experiments of Destroying the Eggs of Hookworms and Ascarids of Dogs in the Soil, by Z. A. Ravevskaja (Ravevskaya) (pp. 560-564); Muscle-Coenurosis of Sheep in Uzbekistan, by L. P. Shibaev (p. 586); The Action of the Albuminous and Lipoidal Substances of Broad Tapeworm on the Blood of Experimental Animals, by N. P. Shikhobalova and N. V. Popova (pp. 587-606); On the Helminthofauna of Sheep in Georgia, by G. N. Shishkin (pp. 607-609); The Metastrongyles of Swine, Their Morphology, and Systematic Position, by R. E. S. Shul'cs (Schulz) and F. O. Kaminskii (Kaminsky) (pp. 615-624); Experiments on the Treatment of Trichostrongylosis of Sheep and Goat, by E. E. Shumakovich (pp. 625-636); The Course of Infection of Pigs With Lungworms of the Genera *Metastrongylus* and *Choerostongylus*, by B. Schwartz and J. T. Lucker (pp. 640-652, Russ. abs. pp. 651, 652) (U. S. D. A.); Some Observations on the Biology of the Nematode *Habronema megastoma* (Rud. 1819), by A. A. Skvortsov (Skvortzoff) (pp. 653-662); Helminthofauna of the *Rangifer tarandus* on the Kola-Peninsula, by B. A. Takhistov (pp. 713-716); The Influence of the Helminthological Factor on the Blood-Picture of Horses, by R. S. Chebotarev (pp. 717-719); A Study of the Efficacy of Natrium Santoninicum Against Ascarids of Pigs When Applied Subcutaneously, by I. A. (J. A.) Shcherbovich (pp. 720-724); The Treatment of Enterobiosis by Carbon Tetrachloride, by S. M. Tuarev (Tuareff) (p. 734); *Diorchis skrjabini* n. sp., a New Cestode Parasite of *Anas circia* L., by A. N. Udintsev (Udintzev) (pp. 735-738); Developmental Stages in Acanthocephalan Life Histories, by H. J. Van Cleave (pp. 739-743, Russ. abs. p. 743) (Univ. Ill.); Pathological Changes of the Pancreas of Sheep Infested by *Eurytrema pancreaticum*, by B. P. Vsevolodov (pp. 758-762); and On the Epizootology of Monieziosis of Sheep, by G. A. Zakharevich (pp. 792-794).

[Contributions on animal pathology and parasitology] (*Indian Sci. Cong. Proc. [Hyderabad]*, 24 (1937), pp. 387, 388, 389, 392, 393, 394, 395, 396-398, 399).—Among the contributions presented are: A Preliminary Investigation Into the Incidence of Enterotoxaemia Among Sheep in the Madras Presidency, by G. R. Viswanathan (pp. 387, 388); Two Unrecognized Forms of Lymphangitis in Horses, by S. C. A. Datta (pp. 388, 389); Urinary Calculus in the Rabbit, by M. Y. Mangrulkar (p. 389); Dissemination of Anthrax Infection Through Dirty Stagnant Pools and Contagious Bovine Abortion in India and Its Significance to Public Health, both by R. N. Naik (p. 392); Two Cases of Natural Acquired Tuberculous Infection in Cows in India Caused by the Human Tubercle Bacillus (pp. 392, 393) and Prevalence of Tuberculosis Among Animals Other Than Domestic Cattle in India (p. 393), both by M. B. Soparkar; Mange Affecting the Horn of Buffaloes and Coccidiosis in Crows, both by R. N. Naik (p. 394); Field Investigation of the Problem of Liver Fluke Infestation Amongst Cattle and Sheep in Hyderabad State, by M. R. Mahajan (p. 394); The Occurrence of Spinose Ear Tick (*Ornithodoros megnini*) in India, by S. K. Sen (pp. 394, 395);

Experiments on the Transmission of Rinderpest Through the Agency of *Stomoxys calcitrans*, by S. K. Sen and A. Salam (p. 395); and A Study of the Life-History of *Cotylophoron cotylophorum* (Fischöeder 1901) Stiles and Goldberger 1910 of Indian Ruminants and a Biological Control to Check the Infection (p. 396), A Study of the Life-History of a Common Tapeworm, *Mesocostoides lineatus*, of Indian Dogs and Cats (pp. 396, 397), Studies on the Helminth Parasites of Indian Poultry—I, A New Fluke From the Oviduct of Fowl (p. 397), II, The Occurrence of Gape-Worms in Fowls (p. 397), and III, The Occurrence of Two Spirurid Stomach-Worms in Fowls (p. 398), A Few Species of Anoplocephalid Tapeworm of the Genus *Bertiella* From a Domestic Pigeon (p. 398), and The Occurrence of an Unrecorded Filariid Nematode, *Onchocerca cervicalis* Railliet and Henry 1910 in the Ligamentum Nuchae of Horses in India (p. 399), all by H. D. Srivastava.

[Contributions on animal pathology and parasitology] (*Indian Sci. Cong. Proc. [Calcutta]*, 25 (1938), pt. 3, pp. 259-261, 262-266, 268-271, 272, 273, 275).—Among the contributions presented at the twenty-fifth Indian Science Congress held in January 1938 are the following: Observations on Bartonellosis in Dogs, by H. N. Ray and J. A. Idnani (p. 259); The Occurrence of Air-Sac Mite, *Cyrtolichus nudus* (Vizdoli 1870), in Fowls in India, by R. L. Kaura and S. G. Iyer (pp. 259, 260); A Form of Vermineous Ophthalmia in Equines, by P. R. K. Iyer (p. 260); Cutaneous Microfilariasis in Indian Cattle (pp. 260, 261), Stomach Worms in the Indian Domestic Ducks (p. 261), Occurrence of Whipworms and Bloodflukes in Indian Dogs (p. 261), Some Unrecorded Helminths From Indian Ducks and Geese (p. 261), and Vermineous Pneumonia in Indian Buffaloes (pp. 262, 263), all by H. D. Srivastava; Surra in Hyderabad State, by M. R. Mahajan (p. 263); Rhinosporidiosis in Bovines in the Madras Presidency, With a Discussion on the Probable Modes of Infection, by M. A. Rao (pp. 263, 264); Rhinosporidiosis in Equines: Record of Another Case in India, by L. Sahai (p. 264); Experiments on the Transmission of Surra (*Trypanosoma evansi* Infection) Through the Agency of *Ornithodoros papillipes* Birula, With Remarks Upon the Bionomics of This Tick, by S. K. Sen (pp. 264, 265); On the Nuclear Structure of *Babesia bigemina* (Smith and Kilbourne), by H. N. Ray (p. 265); Observations on the Forms of *Babesia gibsoni* (Patton) in Dogs, by H. N. Ray and J. A. Idnani (p. 265); On the Occurrence of *Babesia bovis* Starcovici 1893, by J. A. Idnani (p. 265); Bovine Theileriosis—Preliminary Report, by S. C. A. Datta (p. 266); An Outbreak of Equine Encephalomyelitis in a Mounted Military Police Troop in Bihar—A Preliminary Report, by L. Sahai (p. 268); The Incidence of *Salmonella enteritidis* var. *dublin* in Pyosepticaemia of Calves in India, by V. R. Rajagopalan (p. 268); The Incidence of *Corynebacterium equi* in a Buffalo-Cow, by V. R. Rajagopalan and V. R. Gopalakrishnan (p. 268); Neurolymphomatosis in Poultry (pp. 268, 269), Diseases of the Egg-Laying Apparatus of the Hen (p. 269), Leg Weakness in Poultry (p. 269), and Some Common Poultry Ailments Encountered in the Mysore State (p. 269), all by P. M. N. Naidu; A Controlled Epidemic in Guinea-Pig Colony, by K. D. Manohar (pp. 269, 270); A Preliminary Report on the Viability of *Mycobacterium paratuberculosis enteritis* Under Conditions Simulating Those in the Field, by P. C. Banerji and K. Raghavachari (p. 270); Cysteine Hydrochloride As a Suitable Reducing Agent in Glucose Broth for Obtaining Cultures of *Olostridium chauvei* for the Routine Production of Blackquarter Vaccine, by V. R. Rajagopalan (pp. 270, 271); Studies on a Natural Outbreak of Pigeon Pox, by R. L. Kaura and S. G. Iyer (p. 271); Actinomycosis and Actinobacillosis in Animals in India, and Melanomata in Domesticated Animals, both by M. Y. Mangrulkar (p. 271); Changes in Phosphorus and Calcium Content of Blood During Rinderpest Syn-

drome in Hill Bulls, by R. L. Kaura (p. 272); Helminth Parasites of Dogs—Their Treatment and Control (pp. 272, 273) and Verminous Pneumonia in Domestic Animals—Its Control and Treatment (p. 272), both by H. D. Srivastava; and Is Lifelong Immunity Against Rinderpest Conferable on Bovines? by P. C. Banerji (p. 275).

Textbook of comparative physiology, C. G. ROGERS (*New York and London: McGraw-Hill Book Co., 1938, 2. ed., XVIII+715, [pl. 1], figs. [157]; rev. in Ann Ent. Soc. Amer., 31 (1938), No. 4, p. 444*).—A new edition (E. S. R., 56, p. 774).

Poisonous plants and livestock poisoning, O. A. BEATH, H. F. EPPSON, C. S. GILBERT, and W. B. BRADLEY (*Wyoming Sta. Bul. 231 (1939), pp. 104, figs. 64*).—Following a general discussion this practical account deals with (1) plants in which the toxic minerals do not seem to be of special significance (pp. 16-55), (2) plants in which the poisonous properties are influenced by the content of toxic minerals (pp. 56-95), (3) poisonous plants of minor importance (pp. 96-100), and (4) mineral malnutrition (pp. 101, 102). Accounts of the several plants considered, in addition to other data, include place of growth, occurrence, animals affected, poisonous period, symptoms, and treatment.

Goblet cells and age resistance of animals to parasitism, J. E. ACKERT, S. A. ENGAR, and L. P. FRECK. (Kans. Expt. Sta.). (*Amer. Micros. Soc. Trans., 58 (1939), No. 1, pp. 81-89, figs. 4*).—Included in this contribution is evidence that older chickens and older rats have larger numbers of duodenal goblet cells than do younger chickens and rats. "By growing young intestinal nematodes (*Ascaridia lineata* (Schneider)) in artificial culture media into which mucus from the duodenal goblet cells from resistant chickens was introduced, evidence has been obtained which indicates that the duodenal mucus contains an inhibitory factor for growth of the young *A. lineata*." A list of 19 references to the literature is included.

Contribution to our knowledge of parasites in domestic and wild animals in Sweden [trans. title], M. KOFFMAN (*Skand. Vet. Tidskr., 29 (1939), No. 5, pp. 509-585, figs. 64; Eng. abs., p. 585*).—Parasites of the fowl, fox, cat, dog, nutria, rabbit, hare, and guinea pig in Sweden are described.

Bacterial chemotherapy: The pharmacology of sulfanilamide, E. K. MARSHALL, JR. (*Physiol. Rev., 19 (1939), No. 2, pp. 240-269*).—This discussion is accompanied by a list of 179 references to the literature.

Investigations on the sterilization efficacy of gaseous formaldehyde, G. NORDGREN (*Acta Pathol. et Microbiol. Scand., Sup. 40 (1939), pp. IX+165, figs. 12*).—This is a report of investigations of formaldehyde sterilization with regard not only to the bacteriological but also to the physicochemical and practical technical factors. A bibliography of 12 pages is included.

The use of sulfoleum in the treatment of nonparasitic skin diseases, M. W. EMMEL. (Fla. Expt. Sta.). (*North Amer. Vet., 20 (1939), No. 6, pp. 33, 34*).—The use of sulfoleum, a mixture of a light petroleum oil fraction with a vegetable oil admixture and a pentasulfide, has been found of value in the treatment of canker of the ears of mules, rabbits, and dogs.

The preparation of a relatively stable urease concentrate from blowfly [*Lucilia sericata*] larvae, F. C. BAKER (*Jour. Parasitol., 25 (1939), No. 3, p. 280*).—Description is given of a method found to be fairly satisfactory in the removal of a urease ferment from the living blowfly and its preservation without a rather prompt and severe loss of activity.

The use of sulphanilamide in anthrax, C. A. MITCHELL, R. V. L. WALKER, and D. G. MCKECHER (*Canad. Jour. Compar. Med., 3 (1939), No. 5, pp. 119-130, figs. 10*).—Guinea pigs were found to be very susceptible to sulphanilamide and when given in sufficient quantities to maintain a fair amount of free drug in

the blood stream they succumbed to its toxic action. They did, however, live long enough to demonstrate, in the majority of animals inoculated, that anthrax infection was controlled temporarily by its use. "It would seem likely, having regard to the ratio between free sulfanilamide in the blood and its toxicity for guinea pigs, that sulfanilamide should control anthrax in other species of animals where a satisfactory blood level may be maintained."

Three cases of cerebellar agenesis, L. B. SHOLL, E. K. SALES, and R. LANGHAM. (Mich. Expt. Sta.) (*Jour. Amer. Vet. Med. Assoc.*, 95 (1939), No. 749, pp. 229, 230, figs. 3).

The present position regarding *Listerella monocytogenes* infection in animals and man, J. S. PATERSON (*Vet. Rec.*, 51 (1939), No. 28, pp. 873-876).—This account is presented with a list of 28 references to the literature.

Mal-de-caderas in Venezuela (synonym derrengadera), E. MORGAN (*Vet. Jour.*, 95 (1939), No. 5, pp. 178, 179).

Water-borne outbreak of *Brucella melitensis* infection, A. W. NEWITT, T. M. KOPPA, and D. W. GUDAKUNST (*Amer. Jour. Pub. Health*, 29 (1939), No. 7, pp. 739-743, figs. 3).—Report is made of an outbreak of 80 cases of *B. melitensis* infection at East Lansing, Mich., which resulted in 1 death. "All cases occurred in students and others using a bacteriology building which contains a laboratory that handled large numbers of *Brucella* cultures. A faulty technic of sterilization of discarded cultures was demonstrated. Inadequate and faulty plumbing was found in which siphonage could be produced from the point where contaminated glassware was washed."

A preliminary report of the blood picture in brucellosis, M. MUNGER and I. F. HIDDLESON. (Mich. Expt. Sta.) (*Jour. Lab. and Clin. Med.*, 24 (1939), No. 6, pp. 617-619).—In a study of *Brucella melitensis*-infected individuals the blood picture revealed a leucopenia with a relative lymphocytosis and monocytosis. "The red blood cells tend to be slightly smaller than normal; however, some patients gave evidence of macrocytosis. The presence of 'pathologic lymphocytes' in 40 percent of the brucellosis cases is significant. 'Liver damage cells' were found consistently in these patients. Finally the basophilia of the granules of the neutrophils seems to differentiate the *B. melitensis* infection from that of the [*B.*] *suis* and the [*B.*] *abortus* infection."

The classification of the streptococci of bovine mastitis [trans. title], R. B. LITTLE and F. C. MINETT (*Skand. Vet. Tidskr.*, 29 (1939), No. 5, pp. 586-588; *Eng. abs.*, pp. 587, 588).

The rapid identification of *Streptococcus agalactiae*, A. H. BRUECKNER and S. E. HARTSELL. (Purdue Univ.) (*Ind. Acad. Sci. Proc.*, 54 (1938), pp. 35-43).—In work reported an attempt to adapt Neufeld's capsule swelling to group B streptococci failed for lack of a method "of rapidly inducing consistent capsule formation in the species tested. A rapid microscopic agglutination test for group B streptococci is presented. The test has shown close correlation with biochemical tests for the identification of *S. agalactiae*. The test was successful in identifying 98 percent of the freshly isolated strains of this micro-organism. This efficiency is attributed to the methods employed in obviating the difficulties of spontaneous agglutination which are inherent in cultures of streptococci. There is a suggestion that data assembled by the use of the microscopic agglutination test is in accordance with the conclusions of Stableforth [*E. S. R.*, 68, p. 671] in his work on the etiology of mastitis." There are 12 references to the literature.

Second report on the use of large doses of sulfanilamide in the treatment of chronic streptococcal mastitis, W. T. MILLER, F. M. MURDOCK, and J. O. HEISHMAN. (U. S. D. A.) (*Jour. Amer. Vet. Med. Assoc.*, 95 (1939), No. 749..

pp. 140-145).—In continuation of the earlier work (E. S. R., 81, p. 108), "three lactating cows were treated for a period of 6 days with large doses of sulfanilamide in an attempt to cure chronic streptococcal mastitis. A fourth cow which was included in the group died during the course of treatment. The animal was found to be infected with John's disease. Although the streptococci were not permanently removed from the udders of these cows, there was a temporary removal of these organisms from the milk. Each cow received 0.4 gm. of sulfanilamide per kilogram of body weight as the initial dose and 0.2 gm. every 12 hr. for six doses. The amount was then reduced to 0.15 gm. for two doses and to about 0.1 gm. for the three remaining doses. This scaling down of the drug became necessary because of a tendency for the sulfanilamide to accumulate in the blood and milk. This dosage produced a concentration of 20 mg. in 100 cc. and above in the blood and milk which was maintained for 6 days. The three cows which remained in the experiment showed little ill effect from the treatment except for a temporary decrease in milk production and some loss in weight."

Toxicity, therapeutic activity, and mode of action of sulfanilamide in experimental streptococcus infections of rabbits, J. A. KOLMER, H. BROWN, and A. M. RULE, with assistance of M. F. WERNER (*Jour. Lab. and Clin. Med.*, 24 (1938), No. 2, pp. 164-177).—A report on an investigation confined to the study of sulfanilamide in the treatment of experimental lesions.

The use of the incubating egg as a differential medium, H. J. METZGER, F. R. BEAULIEUX, and F. R. STOKES (N. J. Expt. Stas.). (*Jour. Amer. Vet. Med. Assoc.*, 95 (1939), No. 749, p. 158).—The work conducted by the authors has led to the conclusion that incubating hen's eggs may offer a more economical and a faster medium for the study of the occurrence of *Brucella abortus* in milk.

Rocky Mountain spotted fever: Protective value for guinea pigs of vaccine prepared from rickettsiae cultivated in embryonic chick tissues, H. R. COX (*Pub. Health Rpts. [U. S.]*, 54 (1939), No. 24, pp. 1070-1077).—It has been found that vaccine which will protect guinea pigs against Rocky Mountain spotted fever can be prepared from infected embryonic tissues of developing chicks.

Sylvatic plague: Studies of predatory and scavenger birds in relation to its epidemiology, W. L. JELLISON (*Pub. Health Rpts. [U. S.]*, 54 (1939), No. 19, pp. 792-798).—Report is made of field and laboratory observations on the possible relationship of flesh-eating birds to the epidemiology of sylvatic plague in a plague epizootic area in southwestern Montana. It was found that predatory species, especially, transport flea-infested rodents and serve as accidental hosts of rodent fleas. The abundance and variety of rodent fleas found in the nest of a burrowing owl suggest that this species may prove of particular importance. "Casts from predatory birds fed plague-infected guinea pig tissue were consistently infectious. Infection was not demonstrated in two instances in which portions of a plague-infected ground squirrel found dead in nature were used for the infective feedings. Tests on the infectivity of feces of birds being fed plague tissue were consistently negative but were restricted to a few species."

Resistance of the larvae of the common dog tick and their behavior on the human skin, Z. DE JESUS (*Philippine Jour. Anim. Indus.*, 6 (1939), No. 1, pp. 55-60).—A brief account of the brown dog tick, the larvae of which do not attach to the skin of human beings. It is shown that spraying with a liberal amount of a 1-percent solution of lysol or creolin or flushing with hot water will kill most of the larvae which are in the crevices of the floors and walls.

Mice as carriers of pathogenic pleuropneumonia-like microorganisms, A. B. SABIN (*Science*, 90 (1939), No. 2323, pp. 18, 19).—The author's studies indicate that the presence or absence of pathogenic pleuropneumonia-like microorganisms in rheumatic fever and rheumatoid arthritis exudates and tissues will have to be established primarily by cultural methods and not by passage through mice or other animals that may be carriers of similar microorganisms.

Maintenance of echinococcus in the United States, W. A. RILEY. (Univ. Minn.) (*Jour. Amer. Vet. Med. Assoc.*, 95 (1939), No. 749, pp. 170-172).—The author is led to conclude that in the United States the maintenance of hydatid infection in domesticated as well as in wild mammals is due to the fact that wolves play the role of primary hosts.

Sources of error in the agglutination test for Bang's disease, C. R. DONHAM. (Ohio State Univ.) (*Jour. Amer. Vet. Med. Assoc.*, 95 (1939), No. 749, pp. 136-139).

Results of administering sulfanilamide for the treatment of bovine mastitis.—Preliminary report, W. G. STEVENSON (*Canad. Jour. Compar. Med.*, 3 (1939), No. 6, pp. 147-155, 158-160).—In the experiments conducted, the details of which are given in 9 tables, 10 animals known to be harboring streptococci in their udders were each given 648 gm. of sulfanilamide in 8 days. "This dosage of sulfanilamide was incapable of eliminating streptococci from the udder. The dosage employed had very little effect on the appetite, temperature, or amount of milk secreted. The failure of sulfanilamide in the dosage employed to prove of value in the treatment of bovine mastitis may be due to the fact that the temperature was not elevated. It has been pointed out that sulfanilamide at 40° C. possesses bacterial properties, while at 37° it possesses but bacteriostatic properties. Thus, although negative results were obtained in this experiment, had the temperature of the animals been 103° F. or higher, rather than 100.8°, the drug might have proved more efficacious. The sulfanilamide content of the milk from the four quarters of each animal was remarkably similar, not more than 0.2 mg. per 100 cc. difference being noted. The appetite, period of gestation, and clinical symptoms appeared to have no influence on the concentration of sulfanilamide in the blood or milk. The amount of milk secreted per day by an animal appeared to have a slight effect on determining the amount of sulfanilamide in it and in the blood. However, the method of handling the blood and milk collection and the small number of animals prohibit drawing definite conclusions. Three samples of blood tested for sulfanilamide content and stored at ice box temperature for 7 days showed an average decrease of 28.1 percent in sulfanilamide content. Sulfanilamide in the dosage employed in this experiment had no effect on the agglutination titer for brucellosis." A list is given of 33 literature references.

A report on the Hotis test, V. D. FOLTZ. (Kans. State Col.). (*Jour. Bact.*, 38 (1939), No. 2, pp. 233, 234).—Studies are reported which revealed the Hotis test (E. S. R., 76, p. 391) to be in agreement with the microscopic examination in 97.6 percent of all tests conducted in the course of routine control of mastitis in the dairy herd at the Kansas State College. In the study of the group of cows that were supposedly positive for mastitis, in which the leucocyte counts of the milk from one or more quarters were usually, though not necessarily, above 500,000 per milliliter and which furnished 1,167 of the 7,640 quarters examined, a positive Hotis test was given in but 84.3 percent of those samples exhibiting long-chained streptococci on incubation. On the other hand, only 89.1 percent of the samples which were negative on incubated samples were likewise negative for the Hotis test. It is concluded that, despite these

errors, the Hotis test appears to be the most satisfactory that has been developed to date for the field diagnosis of streptococcus mastitis.

Trichomoniasis in cattle: Biological studies and a system of control, W. M. SWANGARD. (Wash. State Col.). (*Jour. Amer. Vet. Med. Assoc.*, 95 (1939), No. 749, pp. 146-151).—The author finds trichomoniasis to be a sexual disease in cattle transmitted only by coitus, and that the causative organism, *Trichomonas bovis*, does not enter the circulatory system of either sex or the urogenital tract of males. The symptoms have been found to vary greatly, and diagnosis must rely on history and microscopy where symptoms are absent. The findings have shown that the disease may be eliminated by proper treatment.

The rôle of the avian tubercle bacillus in the sensitization of cattle to tuberculin, W. H. FELDMAN (*Jour. Amer. Vet. Med. Assoc.*, 95 (1939), No. 749, pp. 152-157).—A summary of findings reviewed as to the ability of the avian tubercle bacillus to infect cattle and to sensitize bovine animals to tuberculin has led to the conclusion that the avian tubercle bacillus has a limited pathogenicity for cattle. "When lesions occur they are in the majority of instances small, localized, and nonprogressive. Instances in which the disease was generalized have not been reported. Under conditions of natural exposure the lymph nodes of the alimentary canal are the sites of predilection for the avian type of infection in cattle. Lymph nodes that appear grossly to be without morbid changes may, by suitable laboratory procedures, yield avian tubercle bacilli. Following natural or experimental exposure to avian tubercle bacilli, most cattle develop sensitivity to avian tuberculin. In cases of natural exposure this sensitivity is usually transitory and eventually disappears if the animals are moved to a noninfected environment. Occasionally, cattle sensitized under natural conditions will react rather typically to mammalian tuberculin. Plum's observations [E. S. R., 78, p. 852] suggest that a definite reaction, but of substandard dimensions, occurs in the majority of cattle that harbor avian tubercle bacilli. It seems not unlikely that in the United States the avian tubercle bacillus sensitizes more cattle to mammalian tuberculin than is generally recognized, and the possibility is suggested that at least some of the so-called nonvisible lesion reactors react to mammalian tuberculin as a consequence of sensitivity induced by avian tubercle bacilli. In areas where tuberculosis of fowl is prevalent and the infective agent exists in excessive concentration, sensitivity due to the avian tubercle bacillus should be seriously considered in reacting cattle from herds in which it is reasonably certain that infection with bovine tubercle bacilli has not occurred."

Colon group bacteria as the cause of acute fatal dysentery in new born calves, J. W. DILLAHUE. (U. S. D. A.). (*Jour. Bact.*, 38 (1939), No. 1, p. 119).—This is an abstract of a contribution which reports on severe losses from dysentery in newborn calves that have occurred over a period of at least 12 yr. in a Government-owned institutional dairy of about 250 animals. "During the first 5.5 mo. of 1938, 49 percent of the newborn calves died with acute dysentery before they were 5 days old. Cultures of *Escherichia communior* and *E. acidilactici* were recovered from a large percentage of these calves that came to autopsy. A normal cow was hyperimmunized against these two cultures of bacteria and an immune serum prepared. Between June 15, 1938, and March 1, 1939, 58 calves were treated with this serum. Of this total treated, 4 calves or 6.9 percent died with dysentery. During the same period 65 calves were left untreated as controls. Fifteen control calves or 23.1 percent died with acute dysentery. Colon-group bacteria were recovered from about 60 percent of these calves that were autopsied."

Toxicity of the coffee bean (*Sesbania vesicaria*) for sheep, I. B. BOUGHTON and W. T. HARDY. (Tex. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 95 (1939), No. 749, pp. 239-241).—Brief report is made of an outbreak of fatal poisoning caused in a farm flock of sheep by eating of ripe seeds of the coffee bean plant (*S. vesicaria*) in February 1939. While the minimum lethal dose of seed was not determined definitely, tests indicate that it lies somewhere between 0.0625 and 0.08125 percent of the body weight. Three mature sheep were fatally poisoned by feeding them 0.25, 0.125, and 0.0625 percent of their body weights, respectively, and two yearling lambs, consuming 0.08125 and 0.0156 percent of their body weights, respectively, were severely poisoned but gradually recovered within 16 days.

In a botanical description of *S. vesicaria*, by L. V. Cory, which is incorporated, reference is also made to other species of *Sesbania* that occur in Texas.

Infectious entero-toxemia of lambs, I. B. BOUGHTON. (Tex. Expt. Sta.). (*Tex. Agr. Workers' Assoc. Mtg., Papers*, 1939, pp. [105-109]).

Anthelmintic efficiency against immature *Haemonchus contortus*, H. McL. GORDON (*Austral. Vet. Jour.*, 15 (1939), No. 2, pp. 57-66, figs. 2).—The results of experiments reported show that the administration of anthelmintic is not as effective against immature as against mature stomach wireworms. "Mixtures of copper sulfate with sodium arsenite and copper sulfate with nicotine sulfate are more efficient than carbon tetrachloride against immature *H. contortus*. Copper sulfate solution appears to be very inefficient. As a result of the general inefficiency of treatment against immature *H. contortus*, treatments must be repeated at about 10- to 14-day intervals during severe outbreaks of haemonchosis. Inefficiency of treatment against immature *H. contortus* offers an explanation for apparent failures of treatment in severe outbreaks of haemonchosis in the field, particularly in those instances in which the treated flock was not moved from infected pastures."

Studies on the bionomics of *Trichostrongylus axei* (Cobbold) and its seasonal incidence on irrigated pastures, M. A. STEWART and J. R. DORRIS. (Univ. Calif.). (*Parasitology*, 30 (1938), No. 4, pp. 477-490, figs. 2).—It is pointed out that with the widespread adoption in California of ladino clover as a pasturage for sheep, especially for feeder lambs, the problem of controlling stomach worms has become increasingly important. Heavy infections of *T. axei* present a particularly acute clinical picture. Investigations reported upon in this contribution were carried on primarily for the purpose of determining the epidemiology of trichostrongylosis under conditions of irrigation. Details of the studies of the life history and bionomics of this parasite, commenced in August 1935, are reported upon. "A mixture of a 1-percent solution of 40 percent nicotine sulfate and 1 percent copper sulfate appears to be a more efficient anthelmintic against *T. axei* than a straight 1-percent copper sulfate solution. Changing from green feed to hay or rendering hay available along with green feed may possibly have a therapeutic effect. Spontaneous recovery, so far as clinical symptoms are concerned, from an acute trichostrongylosis, without the administration of a drug or changing the diet, seems to be common, if not the rule, in the majority of lambs in an infected band."

The effect of tobacco licks used for the prevention of trichostrongylosis in sheep, H. McL. GORDON (*Jour. Council Sci. and Indus. Res. [Austral.]*, 12 (1939), No. 2, pp. 104-108).—In experiments reported, a tobacco preparation containing about 10 percent nicotine, administered either in the form of a lick or by daily dosing with a spoon, did not check the development of trichostrongylosis. This is said to confirm earlier unpublished observations indicating that

tobacco preparations in lick form are of no value in the control of *Trichostrongylus* spp.

Studies on the course of trichostrongyle infestation in sheep, H. S. CAMERON and M. A. STEWART. (Univ. Calif.). (*Jour. Amer. Vet. Med. Assoc.*, 95 (1939), No. 749, pp. 177-180, figs. 2).—Report is made of studies of the age susceptibility of the host, the daily fluctuation in egg count, and the duration of patency of the parasite, based upon egg counts. Lambs at 1 week of age were found susceptible to trichostrongyle infestation. "Resistance and susceptibility based on the fecal egg count are present not only at this age but at more advanced ages as well. There is no apparent difference in the degree of susceptibility between animals 1 mo. of age and those 1 yr. of age. There is a fluctuation in the egg count from day to day in untreated animals. In anthelmintic investigations where efficiency is based upon egg counts it is necessary to make such counts daily over a prolonged period of time. The duration of oviposition is at least 1 yr."

A case of sheep tuberculosis due to the bovine type, E. L. STUBBS and I. LIVE (*Jour. Amer. Vet. Med. Assoc.*, 95 (1939), No. 749, pp. 173-176, figs. 2).—Report is made of the occurrence of a case of tuberculosis in sheep due to the bovine type of the tubercle bacillus. It is pointed out that most of the cases of this disease in sheep thus far typed have been avian.

A case of severe taeniasis and haemonchosis in a young goat, P. S. MANGONON (*Philippine Jour. Anim. Indus.*, 6 (1939), No. 1, pp. 77-79).—A case report of *Moniezia expansa* and *Haemonchus contortus* in a young goat.

Moose encephalitis, L. S. KING (*Amer. Jour. Pathol.*, 15 (1939), No. 4, pp. 445-454, pls. 2).—A description of a subacute or chronic leucoencephalitis occurring naturally in moose, based upon cases in Maine, is presented. "The characteristic picture consists of a mild degree of perivascular demyelination, with formation of neutral fat, and with fibrous gliosis disproportionate in extent to the loss of myelin. There may be mild inflammation restricted to the white matter. There is suggestive evidence that a primary inflammatory reaction involving gray matter and observed in one animal out of eight may represent a separate condition. Attempted animal passage of fresh material from one case was unsuccessful. The etiology of this leucoencephalitis is obscure, although various possibilities are discussed." A list is given of 17 literature references.

Lesions of hog cholera: Their frequency of occurrence, H. C. H. KERNKAMP. (Minn. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 95 (1939), No. 749, pp. 159-166).

Serological studies of swine influenza viruses, R. E. SHOPE (*Jour. Expt. Med.*, 69 (1939), No. 6, pp. 847-856, figs. 2).—In further work with swine influenza viruses (E. S. R., 78, p. 538) cross-neutralization tests with serums from animals that had recovered from the affection indicated the serological identity of seven strains of virus obtained from different sources. "Cross-neutralization tests with serums from rabbits immunized to swine influenza virus exposed serological differences among the same seven swine influenza virus strains. Two strains appeared to be serologically similar and were characterized by the ability to produce effective homologous virus-neutralizing serums which were, however, poor or ineffective against the heterologous virus strains. Two other strains were also serologically similar but produced antibodies effective not only against themselves but against all heterologous strains as well. The remaining three strains were intermediate in their ability to produce heterologous virus-neutralizing antibodies.

"The human influenza viruses included, especially strains WS and Oakham, were most effectively differentiated serologically from the swine influenza

viruses by rabbit antisera. The suggestion is advanced that swine antisera express the antigenic composition of the swine influenza viruses, while rabbit antisera reflect either their antigenic arrangement or the arrangement of the components responsible for their mouse pathogenicity. On this interpretation the seven strains of swine influenza virus studied would be considered to have similar antigenic compositions but differing antigenic structures. The serological differences among strains of the swine influenza virus, detectable by rabbit antisera, are probably of no practical significance so far as the natural disease, swine influenza, is concerned."

A record of twelve outbreaks of paratyphoid disease in pigs in Northern Ireland, P. L. SHANKS (*Vet. Jour.*, 95 (1939), No. 5, pp. 180-185).

Investigations of the piroplasmoses of swine [trans. title], C. G. CERRETTI (*Ann. Parasitol. Humaine et Compar.*, 17 (1939), No. 2, pp. 114-136, pls. 3, figs. 4).—The author finds in work with *Piroplasma trautmanni* K. and d. T. and *Babesiella perroncitoi* n. sp., two forms indistinguishable clinically and anatomo-pathologically, that Acaprine (Bayer) possesses a therapeutic action that is specific for both. The report is presented with a list of 24 references to the literature.

The tick as a vector for the virus disease equine encephalomyelitis, J. T. SYVERTON and G. P. HARRY (*Jour. Bact.*, 53 (1937) No. 1, p. 60).—This abstract of a report of work indicates that *Dermacentor andersoni* (Stiles) may serve as a natural vector in the dissemination of the western strain of the virus of equine encephalomyelitis. "Adult and nymph ticks were allowed to engorge on separate guinea pigs immediately after the pigs had been inoculated with brain tissue-equine encephalomyelitis virus suspension. At intervals of from 32 to 80 days thereafter, successive stages in the developmental cycle of the tick, larvae, nymphs, and adults were fed on different groups of normal gophers or guinea pigs. Infection resulted in these animals. Continuity of the virus through all of the stages in the developmental cycle of the tick, including survival through the egg stage, has been demonstrated. So far, this period of continuity has lasted for 130 days."

On the susceptibility of ground squirrels to the virus of equine encephalomyelitis and ticks as possible vectors, R. GWATKIN (*Canad. Jour. Compar. Med.*, 3 (1939), No. 5, pp. 131-133).—In experiments in which 13 gray gophers (*Citellus richardsoni*) were injected by the intracerebral route with guinea pig brain suspension of equine encephalomyelitis, 9 died of encephalomyelitis in from 48 to 78 hr. after injection and 4 from other causes. Control guinea pigs died from 72 to 104 hr. after being inoculated. "The cause of death in the gophers was confirmed by the inoculation of guinea pigs with gopher brain suspensions and by the absence of bacteria on culture in all cases. The symptoms in gophers were less noticeable than in guinea pigs, as the former do not normally move around as much in their cages as the latter. A healthy gopher which harbored engorged nymphs of *Dermacentor andersoni* when captured was infected with guinea pig brain by the intracerebral route. After death of this gopher, blood was expressed from the ticks, and a suspension of this injected intracerebrally killed one guinea pig, while another was ill but survived. The survivor resisted a challenge inoculation of guinea pig brain 25 days after the first injection, while the control animal died."

The demonstration of phase variation in *Salmonella abortus-equi*, P. R. EDWARDS and D. W. BRUNER. (Ky. Expt. Sta.). (*Jour. Bact.*, 58 (1939), No. 1, pp. 63-72, figs. 2).—A study of the "supposedly monophasic *S. abortus equi* by the Wassén technic revealed that this organism contained three phases. Phase 1 is identical with the flocculating antigens of *S. paratyphi* A. Phase 2 is the form in which the species naturally occurs. Phase 3 is related to, but not

identical with the beta phase of the Schleissheim type. The phases are reversible, and by use of suitable immune serums one phase may be changed to either of the others. This is the first instance in which more than two phases have been demonstrated in a *Salmonella*. It is also the first instance in which induced phases isolated from monophasic specific types have been proved to be reversible."

The use of Neo-Prontosil in strangles. K. L. DOUGLAS and R. V. L. WALKER (*Canad. Jour. Compar. Med.*, 3 (1939), No. 6, pp. 166-169).—Work conducted during an outbreak of strangles among several horses in a cavalry depot is reported. When recognized in the early stages of the disease Neo-Prontosil controlled the infection, rapidly bringing about complete recovery and preventing the suppuration that usually occurs.

Studies upon *Strongylus vulgaris*, II-IV. (Kans. Expt. Sta. et al.). (*Amer. Jour. Hyg.*, 30 (1939), No. 1, Sect. D, pp. 1-27, figs. 5).—In continuation of the studies of the most important parasite of horses in the Manhattan, Kans., area (E. S. R., 81, p. 717), part 2, by J. H. Whitlock, reports upon the Initial Development of Apparatus Adapted for the Study of *S. vulgaris* in vitro (pp. 1-3); part 3, by J. H. Whitlock, R. P. Link, and E. E. Leasure, on The Influence of Hydrogen-Ion Concentration Upon the Longevity of *S. vulgaris* in vitro (pp. 5-14); and part 4, by G. L. Graham, on the Seasonal Variation in the Production of Heterogonic Progeny by Singly Established *S. ratti* From a Homogonically Derived Line (pp. 15-27).

The simultaneous occurrence of the viruses of canine distemper and lymphocytic choriomeningitis. (J. DALIDORF (*Jour. Expt. Med.*, 70 (1939), No. 1, pp. 19-27).—In correcting an earlier contribution (E. S. R., 79, p. 250), an account is given of a particular strain of canine distemper, long maintained by serial passage in dogs and ferrets, which has been found to contain the virus of lymphocytic choriomeningitis in addition to that of distemper.

A note on the action of atropine in the bird. J. D. P. GRAHAM (*Jour. Physiol.*, 93 (1938), No. 3, pp. 56P-58P, fig. 1).—The author has found from experiments conducted with the duck that the effect of atropine on the bird is not identical with its effect on the mammal. "While the absence of pupillary dilatation is explained by differences in histological structure, the dissimilarity in regard to heart and respiration cannot be explained on this basis. The reaction of the gut to adrenaline is noted with interest."

Respiratory diseases [of poultry]: Their prevention and control. J. P. DELAPLANE (*Rhode Island Sta. Misc. Res. Pub.* 4 (1939), pp. [1]+7+[1], fig. 1).—A practical summary of information on respiratory diseases of poultry.

The status of Philippine avian pest in the past ten years. A. B. CORONEL (*Philippine Jour. Anim. Indus.*, 6 (1939), No. 1, pp. 43-54, pl. 1, figs. 2).—An account of avian pest, considered to be the most destructive disease of the avian family in the Philippines, where it has been established for 10 yr.

Fowl leukosis.—IV, Symptoms and pathology. V, Transmission experiments. C. D. LEE and H. L. WILCKE (Iowa Expt. Sta.). (*Poultry Sci.*, 18 (1939), No. 3, pp. 244-254).—A continuation of these studies (E. S. R., 79, pp. 251, 540; 81, p. 118).

In the conclusion drawn from this series of studies it is pointed out that the term fowl leucosis is used to include the group of transmissible leukemic, aleukemic, and leukemiclike diseases of fowls. "The disease in all expressions may be transmitted to healthy chicks by injection of tissue suspensions of affected organs, by injection of cell-free filtrates, by pen contact exposure, or by contact with contaminated soil or litter. The evidence indicates that fowl leucosis is an infectious disease and transmitted by a filtrable virus. The incuba-

tion period of the disease is rather long, with a majority of cases occurring between 4 and 8 mo. The clinical course is variable, extending over a period of weeks or months in some cases, while in others it is comparatively short. No recoveries have been observed, but temporary respites do occur. In the light of our present knowledge it seems rather important that a complete histopathological examination be made of all birds before a definite diagnosis is made. The injection of a suspension made from one type produces all the various manifestations considered to be expressions of this disease. Different suspensions experimentally produce similar results. Neurolymphomatosis associated with iritis, hemocytoblastosis, lymphoid, erythroid, and myeloid types of leucosis are different expressions of the same disease, and all are transmitted by a common etiologic agent. There seems to be a definite inherent difference of susceptibility and resistance in different birds and birds of different strains. The most important methods of control are careful culling, sanitation, and use of breeding stock from resistant sources."

Is paralysis of fowls, as manifested by iritis, transmitted through the egg? (C. F. McCLARY and C. W. UPP. (La. State Univ.). (*Poultry Sci.*, 18 (1939), No. 3, pp. 210-219, figs. 10).—Observations of 227 chickens hatched and grown in isolation from the parent stock revealed approximately 20-percent incidence of iritis, strongly suggesting transmission of the disease through the egg. "High incidence of fowl paralysis in the control group of birds indicated spread by contact. The incidence of iritis in the progeny of parents with iritis was found to be greater than it was in those from parents with normal eyes. Slight cases of iritis did not greatly decrease the mean body weight of individuals so affected. Coccidiosis and parasitic infection apparently played no part in the incidence of iritis in this test. Dipping hatching eggs in chlorine water had no ill effect on hatchability."

A bibliography of 30 titles is included.

Imminence of pullorum: The occurrence of *Salmonella pullorum* in species other than the chicken, H. BUNYEA (U. S. D. A.). (*U. S. Egg and Poultry Mag.*, 45 (1939), No. 9, pp. 562-564, 574).—This summary is presented with a list of 33 references to the literature cited.

Use of the rapid whole-blood test for pullorum disease, H. BUNYEA (*U. S. Dept. Agr., Misc. Pub.* 349 (1939), pp. 18, figs. 9).—A practical account with explicit information concerning the qualifications of a pullorum testing agent, including the details of technic and equipment necessary for the work.

A note on a mortality due to *Salmonella typhimurium* infection among ducks, D. F. STEWART (*Austral. Vet. Jour.*, 15 (1939), No. 2, pp. 67, 68).—A mortality in ducks due to infection with *S. typhimurium* in New South Wales is reported upon.

Erysipelothrix rhusiopathiae associated with a fatal disease in ducks, R. GAHAM, N. D. LEVINE, and H. R. HESTER. (Univ. Ill.). (*Jour. Amer. Vet. Med. Assoc.*, 95 (1939), No. 749, pp. 211-216, figs. 2).—In an outbreak on a farm in Illinois in which approximately 10,000 ducklings succumbed to an acute septicemic disease, *E. rhusiopathiae*, or a culturally and serologically indistinguishable micro organism, was isolated from some of the ducks after death. "The strains of *E. rhusiopathiae* isolated from ducks were pathogenic for pigeons, mice, and ducks. Rabbits and guinea pigs proved resistant to the subcutaneous injection of suspensions of agar cultures. Several healthy, mature birds inoculated with strains of the micro-organism isolated from spontaneously affected ducks remained healthy, suggesting the possible significance of age as a factor in resistance. The influence of environmental factors was suggested by the high mortality in one house in which the birds were subject

to drafts and temperature fluctuations. Attempts to protect ducklings (with erysipelas serum and bacterins) on contaminated premises and environmental conditions under which the spontaneous disease developed were not successful."

A list is given of 18 references to the literature.

Preliminary note on the occurrence of *Leucocytozoon smithi* Laveran and Lucet (1905) in turkeys in the southeastern United States, B. V. TRAVIS, M. H. GOODWIN, JR., and E. GAMBRELL (U. S. D. A. et al.). (*Jour. Parasitol.*, 25 (1939), No. 3, p. 278).—A survey conducted following the finding of *L. smithi* in blood smears from a sick domestic turkey on a plantation near Newton, Ga., revealed the presence of this disease among domestic turkeys in Alabama, Georgia, South Carolina, and Florida, in addition to Virginia, previously reported by Johnson et al. (*E. S. R.*, 79, p. 687). It was also found in wild turkeys in Missouri. Of 10 wild turkeys examined, 5 of which were from Georgia and 5 from Florida, all were found infected with this parasite. Of 447 adult domestic turkeys examined, 369 were infected. "Chickens, peafowls, guinea hens, and ducks were examined on farms where there were infected turkeys, but no leucocytozoa were found in these fowls. Although sufficient data were not obtained in the survey to indicate definitely which species of insect were responsible for the transmission of the disease in the Southeast, it was noted that in low areas in Georgia and Florida where wooded marshes and ponds were numerous nearly 100 percent of the adult turkeys were infected with *L. smithi*. This suggests that some aquatic breeding insect is involved." Although recorded by Johnson et al. from captive wild turkeys in Virginia, it has not previously been reported from turkeys in the wild.

The efficiency of the blowlamp for the destruction of coccidial oöcysts in poultry-houses, C. HORTON-SMITH and E. L. TAYLOR (*Act. Rec.*, 51 (1939), No. 27, pp. 839-842).—In the experiments reported the resistance of coccidial oöcysts to the blowlamp flame was found to be approximately the same as that of *Chromobacterium prodigiosum*. "One second's exposure to the blowlamp flame was found to be sufficient to kill both *C. prodigiosum* and coccidial oöcysts, but approximately 0.5 sec. on rough surfaces sometimes failed to kill both of these organisms. It was found to be necessary to spend more than 2½ sec. in flaming a square foot of clean rough board in order to kill all *C. prodigiosum* that had been painted onto it. *C. prodigiosum* spread in a very thin film of feces onto a square foot of rough board survived 70 seconds' flaming. It is necessary to spend more than 100 sec. in flaming a square foot of smooth wood, rough wood, zinc, or asbestos, if damp, in order to kill all *C. prodigiosum* present. The disinfection of the interior of a poultry house only 20 ft. long and 12 ft. wide by the blowlamp would therefore take from 2 to 16 hr. to complete, and it must be concluded that the blowlamp is a very inefficient means of sterilizing large surfaces. It is thought probable that these results also apply to coccidial oöcysts."

Studies on the development of the pigeon capillariid *Capillaria columbae*, E. E. WEHR (*U. S. Dept. Agr., Tech. Bul.* 679 (1939), pp. 20, figs. 3).—The results of experiments conducted to determine the transmissibility of the pigeon capillariid to chickens and turkeys under natural conditions are reported, together with an account of control measures applicable. The eggs of *C. columbae* were found to develop to the infective stage within 6 to 8 days when kept at room temperature. "Cultures of nonembryonated and embryonated eggs of *C. columbae* suspended in a small quantity of water were found to be very resistant to low temperatures. Nonembryonated eggs were found to be viable and to complete embryonation after an exposure of 35 days to a temperature of -5.6° to -9.4° C. when subsequently exposed to room temperature. Embryonated

eggs were found to be infective to pigeons after an exposure of 14 days to a temperature of -6.7° to -12.2° . Drying for 24 hr. at room temperature destroyed the vitality of partly embryonated eggs. . . .

"The life history of *C. columbae* was shown to be of the direct type. The unhatched embryo has not been observed to molt within the egg. The first-stage larva molts and becomes a second-stage larva early in the second week of infection. The second-stage larva completes its development and molts to the third stage before the fourteenth day after infection. The transition from the third to the fourth stage occurs between the second and third weeks of infection, and mature worms may be recovered from the small intestines of experimentally infected birds as early as 19 days after infection. Eggs have been found in the feces of the birds 26 days after infection. In experimental studies pigeons necropsied 7 mo. after infection were still infested with *C. columbae*. All stages of the worm penetrate more or less deeply in the intestinal mucosa, the larvae being found somewhat deeper than the adults. Necropsies of many birds have shown that most of the worms usually occur in the middle portion of the small intestine. Heavily infested birds showed symptoms of emaciation, diarrhea, and listlessness; food and water were consumed sparingly; and death was usually the termination of severe infestations. For several days prior to death, infested birds spent considerable time in a huddled position on the ground. The feathers were ruffled and those around the vent were usually soiled with fecal material. As observed by the writer, pigeons naturally infested with *C. columbae* showed on post-mortem examination extensive destruction of the mucosa, frequently with complete sloughing of the mucous membrane. The intestines contained large quantities of fluid. Control of this parasite should be directed toward prevention by thorough sanitation and selection of well-drained areas for permanent lofts. Chickens, turkeys, and pigeons should be raised separately, since all three types of birds are susceptible to *C. columbae* infection."

A list is given of 17 references to the literature cited.

Feline septic metritis treated successfully with sulfanilamide, H. GORDON (*Jour. Amer. Vet. Med. Assoc.*, 95 (1939), No. 749, pp. 231, 232).

Schizotaeniasis in muskrats, O. W. OLSEN. (Minn. Expt. Sta. et al.). (*Jour. Parasitol.*, 25 (1939), No. 3, p. 279).—An account of the parasitism of muskrats taken near Ely, Minn., by large numbers of tapeworms (*Schizotaenia variabilis* and *S. americana*).

Notes on the fleas of prairie dogs, with the description of a new subspecies, W. L. JELLISON (*Pub. Health Rpts. [U. S.]*, 54 (1939), No. 20, pp. 840-844, figs. 2).

Resistance of rabbits to larval cestodes, A. B. LEONARD (*Jour. Bact.*, 38 (1939), No. 2, pp. 231, 232).—An abstract of a contribution reporting on the results of the feeding of approximately 2,000 eggs of *Taenia pisiformis* to normal young rabbits, followed by a study of the tissue responses in the liver. A typical inflammatory reaction was found to occur, resulting in the walling off of many of the larvae so completely that further development was impossible. An equal number of rabbits were fed a similar dose of eggs and at the same time given intravenously 55 ml. of serum taken from rabbits carrying a heavy infection of larval cestodes. "In normal young rabbits approximately 500 larvae began development in the liver, the tissue reaction accounting for the death or definite inhibition of growth in all but about a tenth of the total number. An average of 55 larvae per rabbit continued normal development. In rabbits receiving the serum from infected rabbits at the time of infection an

average of 50 larvae began development in the liver. Only an occasional larva was able to continue normal development. The tissue response in the normal rabbit results in walling off the larvae at the end of a period of 16 to 21 days. In immunized animals the tissue response was greatly accelerated, and complete enclosure of the larvae was accomplished in 6 to 7 days."

AGRICULTURAL ENGINEERING

[Agricultural engineering notes] (*Miss. Farm Res. [Mississippi Sta.], 1 (1938), Nos. 1, p. 7, fig. 1; 3, p. 2, fig. 1; 2 (1939), Nos. 1, p. 2; 2, p. 7, fig. 1; 3, p. 5; 5, p. 8; 6, p. 6; 7, p. 2*).—Brief popular articles are presented as follows: Vol. 1, No. 1, Middle Buster Used to Harvest Sweets, No. 3, Mower-Crusher Perfected by Station Cuts Hay Curing Time in Half, and Vol. 2, No. 1, Mechanical Power Displacing Human Labor to Ever-Increasing Extent, all by T. N. Jones; No. 2, Flue Heated Hotbeds for Earlier Plants, by W. S. Anderson; No. 3, Modern Planting Equipment Suitable to Work of Diversified Farms, by T. N. Jones; No. 5, Small-Area Irrigation Is Practicable and Profitable on Many Mississippi Farms, by L. R. Farish; and No. 6, Mower Adjustment, and No. 7, Slope Percentage a Vital Factor in Erosion Control, both by T. N. Jones.

Surface water supply of the United States, 1937.—Part 3, Ohio River Basin (*U. S. Geol. Survey, Water-Supply Paper 823 (1939), pp. VII+575, pl. 1*).—This paper presents the results of measurements of flow made on streams in this basin during the year ended September 30, 1937.

Floods in the Canadian and Pecos River basins of New Mexico, May and June 1937, with summary of flood discharges in New Mexico, T. DALLEY ET AL. (*U. S. Geol. Survey, Water-Supply Paper 842 (1939), pp. IV+68, pls. 9, figs. 7*).—This report presents data pertinent to the floods of May and June 1937, including results of peak discharge determinations made at various points, records of peak stages and discharges and of mean daily discharges during the flood period at 23 regular river-measurement stations, records of rainfall at about 190 places, an isohyetal map showing rainfall over the entire State and two isohyetal maps showing rainfall over the Canadian and Pecos River basins, a discussion of the weather conditions during the flood period, and a summary of records of past floods at all places in New Mexico at which authentic records were available.

The flow of water in the main diversion floodway of the Little River drainage district in southeast Missouri, C. E. RAMSER (*U. S. Dept. Agr., Soil Conserv. Serv., 1939, SCS-TP-22, pp. [17], pls. 7*).—It is noted that although floodways are quite commonly used for flood control, but little reliable information upon which to base their design is available. The investigation here reported upon had the primary purpose of evaluating the coefficient of hydraulic roughness, " n ," in the Kutter formula for cleared and uncleared floodways, and of obtaining related data of value in studies of the hydraulics of floodways. The experiments were made on the main diversion floodway of the Little River drainage district in southeast Missouri. Field surveys were begun in November 1921, and most of the hydraulic data were obtained during the spring of 1922 during a flood stage in the Mississippi River.

The experiments showed, among other results, that where the channel is not located in the center of the floodway the value of n for the floodway on one side of the channel may not be the same as that for the other where the distance from the edge of the channel to either of the levees is small. In one set of measurements, the value of n obtained for the main floodway north of the channel was 0.0462, for the berm south of the channel 0.0366, and for

the channel 0.0329. The lower value of n obtained for the berm south of the channel is attributed to the accelerating influence of the channel velocities. "The narrower the floodway the greater will be this influence upon the value of n . Hence it is seen that the value of n to be used in computing the flow on the narrow berm will likely lie somewhere between the values assumed for the channel and the main floodway. It is advisable, however, in order to be on the safe side, to assume the same value of n for the berm as for the main floodway."

Black Lands experimental watershed—ground water graphs, 1936-37, W. D. POTTER, H. R. BLANK, and C. E. RAMSER. (Coop. Tex. Expt. Sta.) (*U. S. Dept. Agr., Soil Conserv. Serv., 1939, SCS-TP-24*, pp. [2], pls. 20).—The Black Lands experimental watershed comprises about 5,000 acres of gently rolling farm land drained by Brushy Creek and located about 15 miles southeast of Waco, Tex. The underlying geological structure is briefly indicated. Graphs show the elevation of the water in 84 open and cased auger holes during the water year 1936-37, as plotted from manual measurements. Locations of wells are shown on accompanying maps.

Duty of water investigations (New Mexico Sta. Rpt. 1938, p. 78).—Work on duty of water for alfalfa is briefly noted.

Irrigated lands of the Humboldt River area, Nevada, G. HARDMAN, C. VENSTROM, and H. G. MASON. (Coop. U. S. D. A.) (*Nevada Sta. Irrig. Bul. 1* (1939), pp. [3]+36, pls. 14).—The area here dealt with includes all irrigated land in the Humboldt drainage basin of about 9 million acres in northeastern Nevada except that on Reese River and a few scattered farms on other small streams which do not reach the Humboldt. This bulletin presents a general description of the area, its climate, agricultural development, and soils; erosion; alkali and drainage; water supply and irrigation; quality of irrigation water; types of farming; and land classification.

[Tile drainage trial at the Indiana Station], A. T. WIANCKO, G. P. WALKER, and C. ROBBINS (*Indiana Sta. Cir. 244* (1939), pp. 5, 6).—A tile drainage experiment designed to determine the value of tile drainage and the most practical size, depth, and spacing of tile lines on the Clermont silt loam of the Jennings County Experiment Field is very briefly noted.

Terrace outlets and farm drainageways, C. L. HAMILTON (*U. S. Dept. Agr., Farmers' Bul. 1814* (1939), pp. 11+46, figs. 27).—This is designed as a practical guide for the construction and maintenance of terrace outlets and the protection, improvement, and maintenance of drainageways serving as channels of surface drainage for the upper parts of watersheds or in unit drainage basins. It is noted that "the scope of this material is limited to surface run-off disposal measures required in upland or rolling terrain where slopes are steep enough to cause channel erosion. It does not cover surface drainage or underdrainage of flatlands where natural drainage is inadequate."

Public Roads, [June and July 1939] (*U. S. Dept. Agr., Public Roads, 20* (1939), Nos. 4, pp. [2]+65-82+[1], fig. 1; 5, pp. [2]+83-106+[1], figs. 18).—These numbers contain data on the status of Federal-aid grade-crossing, highway, and secondary or feeder road projects, all as of May 31, and June 30, 1939, respectively. No. 4 also contains data on State motor-fuel consumption and tax receipts, motor-vehicle registrations and receipts, and motor-carrier tax receipts, all for 1938, and the following articles: Toll Roads and Free Roads (pp. 65, 66, 75), and Tests of Concrete Curing Materials, by F. H. Jackson and W. F. Kellermann (pp. 67-75). No. 5 contains an article entitled Application of the Results of Research to the Structural Design of Concrete Pavements, by E. F. Kelley (pp. 83-104).

Looped wire for concrete reinforcement, A. R. LEGAULT (*Colorado Sta. Bul. 452 (1939), pp. 22, figs. 7*).—A theoretical consideration of the design of joists indicates a possible reduction of steel costs of approximately 50 percent by the use of ordinary bright, basic wire at a working stress of 30,000 lb. per square inch as is now allowed in the American Concrete Institute Code, and a still greater saving by the use of high tensile-strength steel which would permit steel stresses double those permissible in ordinary reinforcing bars. This bulletin reports four series of preliminary experiments on the design of wire-reinforced concrete joists.

The first series of tests was made to determine the minimum vertical and horizontal spacing of small, smooth wires without decreasing their effectiveness as tension reinforcement. This determination was necessary because wire reinforcing would necessitate crowding from 5 to 50 strands of wire into a 2-, 3-, or 4-in. joist width, and the conventional rules for spacing cannot be used.

The second series had the purpose of determining what steel stress could be developed by embedding the looped wire in concrete and what diameter of loop and depth of embedment gave the best results. No. 8 wire was mostly used in these experiments, and in most cases of comparison gave better results than No. 8.

Series 3 consisted of experiments designed to develop a practical method of anchoring the end of the wire after the coil is wound. For this purpose pieces of the No. 8 wire were bent at the end in various ways, embedded in concrete blocks, and tested for pull necessary to cause slippage.

In the fourth series beams 6 by 6 by 32 in. were made to determine if high elastic-limit steel wire could be made to give results comparable to those obtained with twice the quantity of ordinary reinforcing bars. From this last series of experiments it would appear, in part, that one-half the steel area of high elastic-limit wire will give substantially the same beam strength as the full balanced percentage of ordinary reinforcing bars. The deflections were higher with the high elastic-limit steel, but at working stresses were found not to be high enough to be objectionable.

The cost of using farm machinery in Indiana, E. L. BUTZ and O. G. LLOYN (*Indiana Sta. Bul. 457 (1939), pp. 17, figs. 8*).—This bulletin presents a detailed study of initial cost, operation, maintenance and repairs, age depreciation, and the like. Among other observations, it was noted that most farm implements decrease in value from depreciation far more rapidly than from use.

Economic study of harvesting with the small combine in Indiana, J. C. BUTTUM, W. R. ROTHEBERGER, and I. D. MAYER (*Indiana Sta. Bul. 456 (1939), pp. 21, figs. 8*).—A subtitle of this study restricts the discussion to that of machines having cutter bars 6 ft. or less in length.

The average cost of harvesting 65 acres or more with such machines was less than that of harvesting with a binder and thresher. Average total acre costs for combining with the small machine were less than one-half of the total acre costs of combining with the binder and thresher, and less than one-fifth as much man labor was necessary.

With correct machine adjustment and operation, the small combine saved a higher percentage of wheat and soybeans than did the binder and thresher, but a lower percentage of the oats. The quality of small grains threshed by the small combine, properly operated, was usually equal to that from stationary threshers, but the quality of soybeans was much better. Harvesting with the combine must be done from 7 to 14 days after the normal time for binder cutting for wheat and rye and from 3 to 10 days for oats, barley, and soybeans.

On livestock farms, reclaiming the loose straw cost about \$2 per ton, or, if done by hired pick-up baler machines, the custom charge was \$3 per ton. In grain farming the straw spread on the field is considered an asset.

Detailed analysis of savings as against increased costs on 1 farm of 235 acres showed \$173 increased costs against \$233 savings, or a calculated cash advantage of \$60. The operator of this farm considered the addition of the combine a profitable change.

Farm buildings in relation to farm management in Indiana, L. ROBERTSON (*Indiana Sta. Bul.* 435 (1939), pp. 48, figs. 22).—The average farm of 166 studied in 4 areas in central and northern Indiana had 1 barn, 1 poultry house, 1 brooder house, 1 corncrib, from 1 to 10 (an average of 3) individual hog houses, and 2 or 3 other buildings. Farm business buildings (not including dwellings) represented one-seventh of the total farm capital and had an annual cost of \$1.88 per tillable acre on 767 Indiana farms in 1937. Detailed data on nature, size, location on farm, floor space, storage capacity, type and cost of construction, and other phases are given.

Silo types and construction, J. R. McCALMONT (*U. S. Dept. Agr., Farmers' Bul.* 1820 (1939), pp. II+62, figs. 54).—This supersedes Farmers' Bulletins 825 and 855 (*U. S. R.*, 37, p. 789; 38, p. 190). It discusses various types of silos, and gives data on which to determine the dimensions necessary and much constructional detail in the case of each type. Drawings, dimensioned where necessary, and photographs illustrate this material.

A conspicuously placed warning against gas danger in silos, describing a lighted lantern test for the presence of dangerous concentrations of carbon dioxide and simple means for effecting the diffusion of such accumulations before entering the silo, is included. First-aid treatment of victims of silo gas suffocation is also briefly described.

AGRICULTURAL ECONOMICS

Proceedings of the Fifth International Conference of Agricultural Economists, held at Macdonald College, Canada, 21 August to 28 August, 1938 (*London: Oxford Univ. Press*, 1939, pp. XIV+436, [pls. 2], figs. [5]).—Included in addition to the addresses of welcome, opening address by President L. K. Elmhirst, minutes of the sectional group meetings, and constitution and list of members of the conference, the following papers and discussions were presented: The Social Implications of Economic Progress in Present-Day Agriculture, by J. F. Booth (pp. 27-40) and M. L. Wilson (pp. 41-56) (U. S. D. A.), with discussions by K. Meyer (pp. 56-68), A. W. Ashby (pp. 68-77), J. D. Black (pp. 77-90), O. A. Dawson (pp. 90-92), H. Niehaus (pp. 92-97), E. C. Young (pp. 97-102) (Purdue Univ.), R. D. Craig (pp. 102-110), L. C. Gray (pp. 110-115) (U. S. D. A.), and C. E. Ladd (pp. 115-117) (Cornell Univ.); Land Tenure and the Social Control of the Use of Land, by C. von Dietze (pp. 118-139) and H. C. Taylor (pp. 140-149), with discussions by A. Stewart (pp. 149-155), J. D. Black (pp. 155-158), L. H. Bean (pp. 158, 159) and L. C. Gray (pp. 159, 160) (both U. S. D. A.), V. P. Timoshenko (pp. 160-168), H. C. M. Case (pp. 168-175) (Univ. Ill.), E. Lang (pp. 175-178), S. Higginbottom (pp. 178-181), B. H. Hibbard (pp. 181-184) (Univ. Wis.), I. Szladits (pp. 184-186), H. M. Conacher (pp. 186-188), M. Ezekiel (pp. 188-191) (U. S. D. A.), and G. S. Wehrwein (pp. 191-194) (Univ. Wis.); Farm Labour and Social Standards, by F. W. von Bülow (pp. 198-204) and J. F. Duncan (pp. 205-214), with discussions by W. Seedorf (pp. 214-221), A. H. Brown (pp. 221-227), L. Löhr (pp. 227-229), L. Nelson (pp. 229-234) (Univ. Minn.), M. G.

Egoroff (pp. 250, 251); International Trade in Relation to Agricultural Development, by G. Minderhoud (pp. 256-263) and H. A. Wallace (pp. 264-277) (U. S. D. A.), with discussions by A. Hobson (pp. 277-282) (Univ. Wis.), O. Master (pp. 282-288), G. Mackenroth (pp. 288-294), O. Pfeleiderer (pp. 294-297), A. W. Ashby (pp. 297-301), J. F. Duncan (pp. 301-304), A. Stewart (pp. 304, 305), and S. Schmidt (pp. 305-307); Seigniorial Tenure in Canada, by C. Gagné (pp. 316-324); Some Economic Aspects of Agriculture in Argentina, by P. O. Nyhus (pp. 325-335); Recent Changes in New Zealand's Economic Policy, by A. H. Cockayne (pp. 336-356); Agricultural Co-operation in Canada, by A. E. Richards (pp. 357-367); The Mexican Agrarian Reform, by R. Fernandez y Fernandez (pp. 368-377); National and Local Taxation in Rural Areas, by B. H. Hibbard (pp. 378-386) (Univ. Wis.); Some Remarks on the Land Tenure of the Western Slavs, by S. Schmidt (pp. 387-392); and Recent Agricultural Experience in Eire, by J. Johnston (pp. 393-400).

[Investigations in agricultural economics by the Mississippi Station] (*Miss. Farm Res. [Mississippi Sta.]*, 1 (1938), No. 1, p. 2; 2 (1939), Nos. 1, p. 1; 4, p. 8; 5, p. 1).—The 8-yr. averages for crop yields, milk production, feed costs, returns per cow, net income, etc., on a 14-acre farm operated by the station are reported by J. S. Moore in volume 1, number 1. Volume 2 includes in No. 1 reports by M. Guin of the average costs, expenses, and profits or losses of 66 farmers in growing tomatoes, beans, cabbage, and peas in Copiah County, in No. 4 the average receipts, costs, and profits on 56 dairy farms in Oktibbeha and Lowndes Counties; and in No. 5 an article by H. B. Vanderford showing for two areas of Tishomingo County a correlation between the quality of the soil and types of dwellings and home conveniences.

Current Farm Economics, [June 1939] (*Oklahoma Sta., Cur. Farm Econ.*, 12 (1939), No. 3, pp. 65-94, figs. 7).—In addition to the usual tables of indexes of prices and purchasing power of farm products and demand deposits, the following articles are included: Agricultural Situation, by the staff, department of agricultural economics and extension economists (pp. 67-72); Hog Production in Oklahoma, by P. Nelson and M. Hill (pp. 72-81); Quality, Yield, and Production of Cotton in Oklahoma 1938, by K. C. Davis (pp. 81-88); and Wheat Farm Incomes Highly Unstable, by P. Nelson (pp. 88-92).

[Investigations in agricultural economics by the Rhode Island Station, 1937-38] (*Rhode Island Sta. Rpt.* [1938], pp. 6-10).—Some preliminary findings are included on the effect of feeding roughage to dairy cows, based on the analysis of 6,000 Dairy Herd Improvement Association records covering a 7-yr. period: on the types of farms in the State, changes in crop yields and production costs, and the costs, labor income, etc., on 43 dairy and 40 poultry farms; and on sources of the Rhode Island milk supply, the sales of class 1 milk in the Newport, Fall River, and Providence markets, and the prices in Providence.

Foreign Agriculture, [July 1939] (*U. S. Dept. Agr., Off. Foreign Agr. Relat., Foreign Agr.*, 3 (1939), No. 7, pp. 279-318, fig. 1).—Included are articles on The Soviet Ukraine—Its People and Agriculture, by L. G. Michael (pp. 281-306), Polish Fiber-Supply Policy, by H. L. Franklin (pp. 307-312), and Royal Hungarian Museum of Agriculture, by J. P. Wilson (pp. 313-316), and notes on the Argentine-Brazilian exchange agreement, Colombia to aid the cattle industry, and Taiwan rapidly achieving self-sufficiency in jute.

A statistical analysis of land ownership in North Dakota, 1935, S. WILNER and R. L. SCHAFER. (Coop. U. S. D. A. et al.). (*North Dakota Sta. Bimo. Bul.*,

1 (1939), No. 6, pp. 10-14, figs. 2).—Data are presented as to types of owners and their distribution by counties.

Ownership of farm land in South Dakota, January 1, 1938 (*Brookings: S. Dak. State Planning Bd., 1938, pp. [1]+69, pl. 1, figs. 22; Sup., pp. [1]+91, figs. 82*).—A brief history is included of land settlement, the entry laws, and survey systems. The types of, trends in, and factors contributing to change of ownership, tenancy, and the acquisition, transfer of title of farm lands, and the county ownership patterns are described.

The supplement includes maps showing for the several counties of the State the lands owned by individuals and corporations, public lands, lands occupied by cities and towns, and lands subject to tax deed.

Readjustments of agricultural tenure in Ireland, E. R. HOOKER (*Chapel Hill: Univ. N. C. Press, 1938, pp. XII+245, [figs. 8]*).—Following a description of the historical antecedents of the tenure system prevailing when reforms were begun and the tenure arrangements affecting the various classes of the agricultural population, the experiments in tenure adjustment on the regulation of landlord-tenant relations, transformation of tenants into owners, congested districts, holdings for men with too little land or with no land, and aid to rural laborers are discussed.

The farmer looks at soil conservation in southern Iowa, A. C. BUNCE (*Iowa Sta. Bul. 381 (1939), pp. 117-163, figs. 14*).—Using data obtained in a survey made in 1937, the effectiveness of the program of the U. S. D. A. Soil Conservation Service is discussed.

(Of the farmers cooperating in the program, 55 percent reported that sheet erosion and almost 70 percent that gully erosion had been greatly reduced or stopped. Nearly all stated that farm values had been increased, the average increase being \$5.44 per acre. Over 50 percent of the farmers reported that labor requirements were not affected by terracing, strip cropping, and contouring. Strip cropping and contouring decreased tractor fuel requirements, and contouring made the work easier for horses. In general, the practices and structures introduced met the farmers' expectations, and the farmers reported that with the exception of those requiring large financial outlays or specialized technical knowledge they would continue to use them even if assistance were withdrawn. Practically all the farmers believed the A. A. A. program alone was insufficient to control erosion, but they stated the adjustments had been important in carrying out the conservation program. There was no indication that the reduced acreage of intertilled crops had resulted in a decrease of concentrate-consuming animals fed, and the farmers stated that they intended to increase the number of such animals.

An economic study of land utilization in the tobacco area of southern Maryland, J. W. CODDINGTON and D. E. DERR. (Coop. U. S. D. A.). (*Maryland Sta. Bul. 424 (1939), pp. 161-218, figs. 22*).—This study is based on data secured in previous studies and survey records for 1935 for 160 farms mostly in northern Culvert and eastern Prince Georges Counties, together with farms selected at random in Anne Arundel, Charles, and St. Marys Counties. The characteristics of the area—physical features, number, type, and size of farms, population, trends in land use and tobacco production, tenure and age distribution of operators, size of family, and color of operator are discussed. An analysis is made of the data from the 160 farms as to physical characteristics, land utilization, extent of farm operations, diversification of enterprises, consumption needs in relation to home production, and farm returns. Findings for the 40 farms with the lowest percentage of crop land lying idle and the 40 farms with the highest percentage are compared. Some of the findings were: The

difference in the percentages of tillable land were insignificant and both groups could increase the tobacco acreage about 100 percent with a 2-yr. rotation; the high idle group had more land available for diversification of crops but a much smaller amount was so used; the relationship between soil type and topography was similar in both groups; the low idle group had approximately 66 percent of its land in the least erosive class and 5 percent in the most erosive class as compared with approximately 10 and 49 percent, respectively, in the high idle group; the investment per farm was \$2,820 higher in the low idle group, but there were only small differences in the distribution; the low idle group averaged six more animal units per farm, having twice the number of cattle and poultry; for the low idle group the average total receipts were \$2,773, of which \$1,878 was from tobacco, \$492 from dairying, and \$145 from poultry; total expenses were \$1,385 and labor income \$948; the average total receipts in the high idle group were \$1,624, of which \$1,358 was from tobacco and less than \$100 from dairy and poultry; and total expenses were \$714 and labor income \$611.

Certain economic aspects of agriculture in the Jackson County soil-conservation area, E. C. WITZELL. (Coop. U. S. D. A.). (*West Virginia Sta. Bul.* 291 (1939), pp. 56, figs. 9).—This is a progress report covering the first year's changes on 187 farms in the soil conservation area. The topography, soils, climate, social aspects of the farm families, size of farms, farm investment, land use, farm practices, crop and livestock production, agricultural and nonagricultural income, farm receipts and expenses, etc., in 1935 and 1936 are discussed. The types of farming in 1936 in the area and the program of soil conservation are described. Some of the changes per farm from 1935 to 1936 were: Size of farm increased 3 acres; areas in crops, permanent pasture, and woods not pastured increased 0.3, 4, and 3.5 acres, respectively, and that in woods pastured decreased 2.4 acres; the percentages of cropland in erosion-resistant and semiresistant crops increased 2.5 percent and 1.5 percent, respectively, and that for nonresistant crops decreased 4 percent; animal units increased 0.4; total agricultural receipts increased \$177, consisting of a decrease of \$4 for crops and an increase of \$161 from livestock and livestock products, and \$20 from miscellaneous receipts; nonfarm receipts increased \$67; operator's labor income increased from —\$204 to —\$102; and operator's earnings (labor income plus nonfarm receipts and value of perquisites) from \$333 to \$499. The average labor incomes and operator's earnings in 1936 from different types of farms were: General farms —\$137 and \$482, beef farms —\$99 and \$603, dairy farms \$958 and \$1,563, poultry farms —\$53 and \$529, self-sufficing farms —\$133 and \$204, and part-time farms —\$477 and \$647.

Cost and utilization of power and labor on Iowa farms, W. D. GOODSELL (*Iowa Sta. Res. Bul.* 258 (1939), pp. 317–363, figs. 10).—This study is based upon the actual experiences of 1,961 farmers as shown by 869 farm management association records, 842 nonassociation records, 425 tractor and 125 horse records, and approximately 250 farm survey records kept or obtained in 1936 and 1937. The types of power on the cooperating farms are described. Analysis is made of the costs of operation of horses, tractors, and trucks; the horse, machinery, tractor, and man-labor costs on horse, standard tractor, and general-purpose tractor farms; and the performance of tractors and horses in farm work. A comparison is made of the organization and management of farms of similar size and having similar amounts of livestock but operated with different types of power, including discussion of the effect on costs of length of time a given type of power has been used, the influence of type of power on land use and crop yields, and the sources of income on farms operated with different types of power.

The general-purpose tractor farms were considerably larger than the standard tractor farms, which were larger than the horse farms. The average hours of horse work per farm were 814 in 1936 and 802 in 1937, and the average costs per hour were 11.2 ct. and 10.7 ct. The average number of hours varied from 680 on farms with approximately 75 acres in crops to 854 on farms with about 375 acres in crops. Feed costs per horse varied from \$56 to \$71. The amounts of roughage fed did not differ with size of farm or hours worked. The pounds of grain fed per horse varied from 2,050 on the smaller to 4,518 on the larger farms, due to the larger number of hours the horses were worked. Operating costs per hour and horsepower hours for different types and sizes of tractors were: General-purpose 1-plow 54 ct. and 5.5 ct., general-purpose 2-plow 52 ct. and 4.7 ct., general-purpose 3-plow 60 ct. and 5.2 ct., standard 2-plow 63 ct. and 4.9 ct., and standard 3-plow 70 ct. and 4.4 ct. Tractors on pneumatic tires used 22 percent less fuel and had an estimated life 34 percent longer than steel-wheeled tractors, but these economies were offset by tire costs. The average yearly mileage and costs of operation per mile for farm trucks were: $1\frac{1}{2}$ -ton 3,024 and 6.3 ct., 1-ton 3,660 and 5.1 ct., and $\frac{1}{2}$ -ton 5,441 and 3.9 ct.

Labor costs per acre were slightly higher on horse farms than on tractor farms of comparable size, but there was no consistent difference in the combined costs for labor, horses, tractors, and machinery on general-purpose tractor and horse farms. Those on standard tractor farms were higher. On general-purpose tractor farms 4.9 hr. of man labor and 27.46 drawbar horsepower hours, and on horse-operated farms 9.4 hr. of labor and 30.88 drawbar horsepower hours, were used per acre of corn up to harvest. Managerial ability of the farm operator was the most important factor in power costs.

Flue-cured tobacco farm management, F. L. UNDERWOOD (*Virginia Sta. Tech. Bul.* 64 (1939), pp. 313, figs. 8).—The analyses in this bulletin are based on survey records for 1933 from 620 tobacco and 47 nontobacco farms in central Pittsylvania County. The climate, elevation and topography, soils, soil erosion, transportation facilities, markets, etc., of the area are described. An analysis is made of the farm business—capital, crops, livestock, farm practices, receipts, expenditures, profits, etc., and the factors affecting farm income—rate of production, labor efficiency, horse and machinery efficiency, size of business, capital efficiency, soil erosion, specialization or balance of the business, and personal factors, such as age, education, color, and tenure of operator. A more detailed analysis is made for the tobacco enterprise of the costs and practices in growing, harvesting, curing, and marketing, and the effects on costs and returns of such factors as acreage, varieties, yields, prices, quality, etc., size of the tobacco business, factors affecting prices, soil factors, fertility practices, distribution and efficiency of labor, etc.

For the entire farms the averages were: Acres operated 142, percentage of acreage in crops about 25, receipts \$879, expenses \$730, labor income —\$92, number of work animals 2.08, and number of other animal units 3.27. For the tobacco enterprise the averages were: Acres 8.3, yields 642 lb. per acre, price \$13.67 per 100 lb., production costs \$126.70 per acre, days of labor per acre 44, net return per acre —\$39, and returns per hour of labor 10.8 ct. Total production costs per acre were about \$100 less and net profits \$120 to \$130 higher on the larger than the smaller acreages. Yields of 800 lb. or more per acre returned 15 to 18 ct. more per hour of labor than did yields of less than 500 lb. Efficiency in labor used was the most important factor affecting production costs. Farms on which the work units per man were 270 or more had a labor income averaging \$528 more than those farms having less than

150 work units per man. In general, large businesses were the most profitable. With less than \$1,500 total capital tenants fared better than owner-operators, and with less than \$250 croppers fared better than tenants. The farms with the best balanced businesses were the most profitable. Under comparable conditions the labor incomes of white and colored operators were about the same. Under similar conditions as to size and quality of farm, tenants had larger labor income than owners. As between farms, the most important factor affecting the variation in income was quality of the tobacco crop and the second yield per acre.

An economic study of milk distribution in Maine markets, G. F. Dow (*Maine Sta. Bul.* 395 (1939), pp. 523-674, figs. 11).—Detailed cost records and other information as to labor utilization, use of equipment, volume of sales, sales outlets, credit granted, source of milk supply, investment, etc., were obtained by personal interviews for the year ending April 30, 1935, from 126 milk distributors in the Portland, Waterville, and Bangor areas, and for the year ending April 30, 1936, from 140 distributors in seven somewhat smaller areas throughout the State. The distributors interviewed comprised 43 percent of those in the areas, and handled approximately 75 percent of the total volume of milk and cream sold. The market areas, business conditions, milk supply, State and municipal milk regulations, kinds of milk and cream sold, volume of sales, prices, etc., are described and discussed, and various factors are analyzed.

The milk sales comprised 87 percent of the total butterfat distributed in the seven smaller markets, and 75 percent in the three larger markets. Cost of dairy products constituted nearly 60 ct. per dollar of sales, and distribution costs (including interest on capital at 5 percent), 43 ct. for the four large distributors and 30 ct. for the smaller distributors. The net income or profit for distributors of raw milk varied from 8 ct. for the small to 16 ct. for the large distributors, and from 14 ct. for the small distributors to a loss of 3 ct. during the year preceding the establishment of the State milk control for the large distributors of pasteurized milk. The rate of profit was approximately the same on wholesale and retail sales and for milk and cream. All distribution costs of retail milk averaged 4.36 ct. per quart, of which man labor comprised about 50 percent, depreciation and repairs 9.3 percent, taxes 6 percent, and other costs 33.7 percent. Plant costs averaged 36 percent, containers 5 percent, selling and delivery 51 percent, and administration 8 percent. Labor used by raw milk distributors was 5.5 hr. per 100 qt. when the volume of milk distributed was large, and 8.5 hr. where it was small. Distributors of pasteurized milk used slightly less labor but had considerably higher costs due to higher wages. Expenditures for advertising per \$100 of sales was 1 ct. for the small raw milk distributors, 13 ct. for the larger raw milk distributors, and \$1.27 for the four large distributors of pasteurized milk. Costs per 100 qt. were: Equipment 12 ct. for raw and 29 ct. for pasteurized distributors, use of buildings 8 ct. and 17 ct., respectively, milk loss 10 ct., and containers 15 ct. Bad debts and interest on accounts receivable averaged 2.1 ct. per \$1 of sales. The four large distributors in the Portland market delivered 308 qt. per route daily of retail milk equivalent at an average cost of \$2.94 per 100 qt. as compared with 130 qt. for all other distributors at average costs varying from \$1.44 for the larger volumes to \$2.13 for the smaller volumes, averaging \$1.55.

An economic study of the hatchery industry in Maryland, P. R. Poffenberger and S. H. DeVault (*Maryland Sta. Bul.* 426 (1939), pp. 235-289, figs. 9).—One hundred and ten hatcheries located throughout the State were studied

for each of the 2 yr. ended June 30, 1938. The development of the industry, the number, functions, types, capacity, etc., of hatcheries in the State, the seasonality of business, sources of and prices paid for eggs, sources of and quality of chicks purchased by Maryland poultrymen, relation of hatchability to egg costs, disposition of and method of delivering chicks, etc., are described. An analysis is made of the various costs in hatching and marketing chicks, and the effects of different factors on profits. Comparisons are made between the 27 most profitable and the 27 least profitable hatcheries.

The average profit per 100 chicks hatched was \$3.22 for the most profitable hatcheries, —\$1.02 for the least profitable, and \$1.84 for all hatcheries studied. The average number of chicks hatched and costs for fuel per 100 chicks were approximately 120,000 and 14 ct., 29,900 and 35 ct., and 116,900 and 18 ct., respectively, for the most profitable, least profitable, and all hatcheries. The average labor costs and investment per 100 chicks were 46 ct., \$1.53, and 68 ct., and \$1.30, \$15.82, and \$5.02, respectively. The percentages of hatchability of eggs set were 72.6, 67.2, and 71.6, respectively. Losses were sustained when cost per 1,000 chicks hatched exceeded \$4.50 for fuel and \$13 for labor.

The largest profits were made where the egg cost per 100 chicks hatched was \$2.99 or less. Profits increased from 80 ct. per 100 chicks when the hatchability was below 65 percent to \$2.23 when it exceeded 75 percent. Average profit per 100 chicks was 23 ct. higher for hatcheries using eggs from pullorum-tested flocks than those with eggs from nontested flocks. The hatcheries paying a premium of 10 ct. or more per dozen for eggs had the highest selling price and profit per 100 chicks sold. Profits per 100 chicks hatched with different numbers hatched were: 9,999 or less —88 ct., 10,000 to 19,999 46 ct., 20,000 to 39,999 \$1.53, and 80,000 or more \$1.82. Profits increased from \$1.09 where the hatchery capacity was 9,999 chicks or less to \$1.88 where it was 80,000 or more chicks. Hatcheries not used to capacity showed a loss of \$1.89 per 100 chicks. Those setting 2 to 2.9 times and 5 times and over the capacity showed profits of \$1.98 to \$2.01. Hatcheries with average selling prices of less than \$2 and from \$3 to \$4 per 1,000 chicks had the highest profits. Profits increased as the number of days the hatchery was operated increased.

How the Government aids the poultry industry, J. W. KINCHORNE and R. E. MILLER. (U. S. D. A. et al.). (*Washington: Govt., 1939*), pp. [I]+IV+72+[I], figs. 56).—This publication was prepared to supplement the exhibits of the Federal Government at the Seventh World's Poultry Congress and Exposition held at Cleveland, Ohio, July 23–August 7, 1939 (E. S. R., 81, p. 465).

Agricultural Marketing Service: Organization and functions, C. W. KITCHEN ET AL. (U. S. Dept. Agr., Agr. Market. Serv., 1939, pp. [4]+95, figs. 4).—The general services and divisional activities of the Agricultural Marketing Service are described.

Egg auctions: Selected references, H. BROWN (U. S. Dept. Agr., Bur. Agr. Econ., Econ. Libr. List 4 (1939), pp. 20).—This mimeographed list includes 88 annotated references.

Year book of agricultural co-operation, 1939, edited by THE HORACE PLUNKETT FOUNDATION (London: P. S. King & Son, 1939, pp. VII+558. [figs. 2]).—Included are articles on Agricultural Co-operation in 1938 (pp. 1–15); Sir Horace Plunkett as Co-operator, by H. F. Norman (pp. 16–48); Agricultural Co-operation in the World Today, by C. R. Fay (pp. 49–58); Co-operation and the State, by Prof. Ashby (pp. 59–77); The Phosphate Co-operative Company of Australia, by A. Wolskel (pp. 78–95); The Co-operative Society in Rural Hygiene, by H. A. Izant (pp. 96–108); The Building of Agricultural Co-operation in Turkey, by H. Wilbrandt (pp. 109–132); Communitarian Rural Settlements

in Palestine, by H. Viteles (pp. 133-153); and Co-operation in Mexican Agriculture, by G. Fabila (pp. 154-183); and articles by different authors on cooperation in various countries, review of legislation during the year, lists of books, surveys, and reports published during the year, and a selected bibliography.

Principles and procedure for organizing cooperative cotton gins, O. T. WEAVER and U. H. PRICKETT (*Farm Credit Admin.* [U. S.], *Coop. Res. and Serv. Div., Misc. Rpt. 17* (1939), pp. [3]+62).—Some of the desirable features of a cooperative gin, local factors important in determining whether such a gin is needed, and the financial structure and dividend policy of cooperative gins are discussed. The steps in the organization procedure are outlined, and suggested forms for organization papers are included.

Crops and Markets, [July 1939] (*U. S. Dept. Agr., Crops and Markets, 16* (1939), No. 7, pp. 125-152, figs. 2).—Included are the crop and market reports of the usual types. Tables show by States the acreages, estimated yields, and production July 1, 1939, of important crops, and the stocks of corn, oats, and old wheat on farms July 1, 1939.

Index numbers of Idaho farm prices, C. O. YOUNGSTROM (*Idaho Sta. Mimeog. Leaflet 34* (1939), pp. 22, fig. 1).—This mimeographed circular brings the tables in Bulletin 210 (E. S. R., 73, p. 866) up through February 1939.

RURAL SOCIOLOGY

[Sociological studies in New Mexico]. (Partly coop. U. S. D. A.). (*New Mexico Sta. Rpt. 1938*, pp. 11-14).—The topics for which data are reported are the economic and social effects of a definitely planned program of soil conservation; and market outlets and local uses for fruits, vegetables, and field crops produced in New Mexico.

[Investigations in rural sociology in Rhode Island] (*Rhode Island Sta. Rpt. [1938]*, pp. 51-56).—Topics discussed are a study of the characteristics and occupations of 1,100 part-time Rhode Island farmers, and some characteristics of the rural population.

Planning for a permanent agriculture (*U. S. Dept. Agr., Misc. Pub. 351* (1939), pp. III+71).—This publication, prepared for the use of community and county land-use program planning committees, summarizes the programs administered by the Department that influence the use of the land.

Educational deficiency, low income, handicap daughters and sons of underprivileged, D. DICKENS (*Miss. Farm Res. [Mississippi Sta.] 2* (1939), No. 6, p. 2).—This discussion is based upon Bulletin 318 (E. S. R., 78, p. 128). Public provision of more educational facilities than in the past is discussed as one of the most important means of improving the occupational situation of the young people in the State.

An analytical study of a rural school area, H. L. FULMER (*South Carolina Sta. Bul. 320* (1939), pp. 71, figs. 47).—This study is based largely on conferences with parents, pupils, and teachers for 10 rural school districts in the western part of Pickens County in northwestern South Carolina, data being collected as of the 1936-37 school year. The average cash income per family was below \$325 per annum, and only \$297 of property per pupil was available for taxation. Only \$4.54 per pupil was allowed for school purposes.

A close relationship was found between "the environment of the homes, the taxable resources, and the efficiency of the schools. . . . The small district school system is the insurmountable obstacle in the way of the school progress of these rural children. . . . An administrative unit large enough to permit a

complete general school program with all necessary administrative services is needed. A consolidated or centralized school would prove of great social and educational value to this rural community." "The aid for building as well as for operating will, however, have to come from outside many of these small districts," and the provision of State and Federal aid for these purposes is advocated.

AGRICULTURAL AND HOME ECONOMICS EDUCATION

Teaching dairy-cattle selection, W. B. NEVENS and A. F. KUHLMAN (*Illinois Sta. Cir. 495* (1939), pp. 27, figs. 10).—This is a manual for the use of leaders of 4-H club dairy products to supplement Circular 486 (E. S. R., 80, p. 386).

FOODS—HUMAN NUTRITION

Adjustments in agriculture and family living needed for improved nutrition in the South (*Assoc. South. Agr. Workers Proc., 40* (1939), pp. 35-39).—Abstracts are given of the papers comprising this symposium as follows: Nutrition as a National Problem, by G. Hambidge (U. S. D. A.); Changes in the Southern Diet Suggested by Food and Nutrition Research, by J. Whitacre (Tex. Expt. Sta.); The Functions of Community Storage Lockers in Relation to the South's Nutrition Problem, by K. Beach (La. State Univ.); Changes Needed in Southern Agriculture for the Production of Adequate Food Supply, by O. Steanson (U. S. D. A.); and Adjusting Family Living for Improved Nutrition, by L. Collier.

Plant, animal, and human nutrition in relation to social and economic life of the South (*Assoc. South. Agr. Workers Proc., 40* (1939), pp. 27-30).—Abstracts are given of the papers comprising this symposium, in which plant nutrition is considered by J. E. McMurtrey (U. S. D. A.); meat in animal and human nutrition by C. A. Elvehjem (Univ. Wis.); and human nutrition by C. Winters (Univ. Tex.), with discussion by O. D. Abbott (Fla. Expt. Sta.).

A tested scale for evaluating food production for farm families, D. DICKINS (*Miss. Farm Res. [Mississippi Sta.], 1* (1938), No. 1, p. 7).—The yearly food supply scale developed for use in the investigation reported in Bulletin 320 (E. S. R., 79, p. 142) is given, with a brief explanation of its use.

[Foods and nutrition research by the New Mexico Station] (*New Mexico Sta. Rpt. 1938*, pp. 61-65, figs. 4).—Further progress is reported in the study of the flavin and vitamin B₆ content of pinto beans and the effect of cooking on these factors (E. S. R., 79, p. 129).

The physical and chemical characteristics of lards and other fats in relation to their culinary value.—II, Use in plain cake, B. Lowe and P. M. NELSON (*Iowa Sta. Res. Bul. 255* (1939), pp. 145-216, figs. 4).—This report is based upon a series of graduate theses by E. L. Martin, E. I. Buel, L. C. Minard, and E. Myers working under the direction of the senior author. The lards and other fats used throughout the investigation were the same as noted in the previous report of the series (E. S. R., 80, p. 704). A single recipe was used but with several methods of combining the ingredients. Other factors studied for their effect on the quality of cakes made with the various shortening agents were the creaming qualities and volumes of the different fats, the relation of creamed volumes to cake volumes and to cake scores, the relation of humidity to cake scores, the effect of viscosity of the batter on cake texture and scores, the effects of different kinds of fat and texture of the fat, and the temperature of the ingredients when combined.

Among the objective tests used for rating the cakes were a new test for tenderness called the breaking angle test which is described and illustrated, the texture index or sand retention test of Swartz (E. S. R., 80, p. 132), and microscopic examination of the cakes by a technic developed by Minard under the guidance of E. R. Becker. This was used to observe the fat distribution in the cakes as affected by kind of fat, temperature, and method of combining.

The time required to reach the maximum volume during the creaming process was found to depend on the speed of agitation, the quantity of material, the proportion of fat to sugar, the kind of fat, and the temperature of the ingredients. The time varied from 8 to 210 min. of slow mixing with an electric mixer for the 42 fats used. For each fat there was an optimum temperature for creaming, which was lower for soft fats than for firm fats. Smooth lard creamed to a larger volume than grainy lard from the same source at both 25° and 30° C. A 1 : 1.3 proportion of fat to sugar gave greater creaming volume than a proportion of 1 : 2.6. With the latter proportion and a creaming period of 30 min. at the slow speed of Kitchen Aid and the temperature of ingredients and air from 24° to 25° the creaming volumes for the different fats in decreasing order were hydrogenated lard, hydrogenated cottonseed oil, open-kettle rendered lard, animal husbandry composite lards, animal husbandry individual lards, butter, and prime steam-rendered lard. Comparable volumes were secured with 5-min. creaming by hand. Smooth lards when soft and plastic but not waxy yielded higher scoring cakes than grainy lards. Palatability was affected by the kind and texture of the fat and by the method and temperature of combining the ingredients.

All of the data point to the method of combining the ingredients as one of the most important factors in the quality and palatability of cakes, particularly when made with lard. The effect of different combining methods on the distribution of fat in the cake was strikingly brought out in the microscopic studies. Methods in which the egg is added to the milk or added last, either with or without a portion of the sugar to the batter, improved markedly the quality and palatability of cakes made with oils and to almost as great an extent of cakes made with lards. Even cakes made with butter usually ranked higher when the egg was added last than when added to the creamed mixture. Of all the methods tried, the conventional sponge in which one-half of the sugar is beaten into the egg to form a light fluffy sponge and folded into the cake batter last was outstanding.

Studies on all-purpose flour, M. V. DAVIS and E. G. HALLIDAY (*Cereal Chem.*, 16 (1939), No. 3, pp. 414-418).—Five brands of so-called all-purpose flour from different parts of the country were analyzed for protein and moisture content and used with standard recipes in making butter cake, yeast bread, and baking powder biscuits, which were scored in three series for each product. The flour with the highest protein content gave the highest score for bread and biscuits and one of a lower but not the lowest protein content for cake. The total scores for the three products did not vary widely, ranging from 250 to 260 on the basis of 100 for each product.

Several objective tests were also used on cakes made from the various brands and also a brand of cake flour. The index to volume test of Platt and Kratz (E. S. R., 69, p. 462) gave comparable results for the different all-purpose flours but a considerably higher figure for the cake flour. The compressibility test gave a higher figure for cake flour on the first and second days, but on the fourth day after baking the value was lower than for one of the all-purpose flours. Moisture absorption was also higher for the fresh sample made from cake flour but decreased considerably more than that of the other flours after 3 days.

The sand retention values by the method of Swartz (E. S. R., 80, p. 132) were comparable for all the flours. In breads the loaves made from the all-purpose flour with the highest protein content had the highest index to volume and from the flour with the lowest protein content the lowest. All but one of the flours gave similar results with the compressibility test, but there was no significant difference in the oven spring or the amount of water required to make a dough. With biscuits all of the flours ranked high on the main points of texture, flavor, crumb color, and volume, but there was considerable variation in symmetry, crust color, and character of the crust. The authors conclude that all of the flours tested may rightfully bear the label all-purpose.

A study by the paired feeding method of the nutritive value of bread made with milk solids, B. W. FAIRBANKS. (Univ. Ill.). (*Cereal Chem.*, 16 (1939), No. 3, pp. 404-414).—In this extension of an earlier study (E. S. R., 80, p. 131) controlled feeding technic was used, and in addition to records of the body weights of the experimental rats body lengths were determined. At the end of the experiment the carcasses of the animals were subjected to analysis for proximate and calcium and phosphorus composition. Each of the seven groups of rats consisted of three carefully matched animals, one of which was fed a no-milk bread and the other two breads containing 6 and 12 percent, respectively, of milk solids. The bread with distilled water constituted the sole diet, which was fed for 49 days to produce equal gains and then for 56 days in equal amounts to the three animals in each group. Because of the limited diet only three groups survived to the end of the period. The other groups were sacrificed when the first animal in the particular group died. The data obtained were analyzed statistically by the method of Student.

By the method of feeding for equal gains the rats receiving the milk solids breads were significantly longer than those receiving the no-milk bread, and the difference between the results for the 6 and 12 percent milk solids breads was significantly in favor of the larger amount. By the method of feeding equal amounts the differences in body length were also significant. The weight gains were significantly greater for the animals receiving the milk solids, but the differences between the two levels were not significant. Analysis of the chemical data showed no significant effect of the milk solids or protein, gross energy, or fat content; a significant increase in the ash and phosphorus content, but with no significance between the two levels of milk solids; and significant differences in the calcium content, with a significance between the two levels. The previous conclusion that the addition of milk solids to a no-milk bread increases the nutritive value of the bread has thus been confirmed, and "the burden of the evidence supports the conclusion that in practical nutrition the nutritive value of the 12 percent milk solids bread is of a higher order than that of the 6 percent milk solids bread."

Observations on the hydrogen-ion concentration of cakes, O. E. STAMBERG and C. H. BAILEY. (Minn. Expt. Sta.). (*Cereal Chem.*, 16 (1939), No. 3, pp. 419-423, fig. 1).—Observations are reported on the pH of commercial cakes and the effect of alterations in certain ingredients on the flavor, eating quality, and pH of white and yellow cakes baked in the laboratory. In the commercial cakes a series of 6 white cakes gave an average pH of 7.47, 3 yellow cakes of 7.59, 8 chocolate cakes of 8.48, and 4 angel food cakes of 5.67. The highest scores for the laboratory-produced cakes were given in both yellow and white cakes as those within a pH range of 7.0-7.9. Outside this range the cakes were distinctly inferior when baked with either a phosphate or a tartrate baking powder. The pH was affected chiefly by the baking powder both in terms of quantity and of quality. Dry milk solids had little effect on the pH, and there was no appreciable change in pH on storing the cakes for 3 days.

Vegetables have added food value, O. SHEETS (*Miss. Farm Res. [Mississippi Sta.]*, 2 (1939), No. 5, p. 2).—Attention is called to insufficiency of iron as the most common defect in the diet of many farm families in the South. The function of iron in hemoglobin formation and prevention of anemia is discussed, and tabulated data are given on the hemoglobin-regenerating properties of the common leafy vegetables and legumes of the South.

Variations in cooking quality of potatoes as influenced by varieties, J. L. HADDOCK and P. T. BLOOD (*Amer. Potato Jour.*, 16 (1939), No. 5, pp. 126-133; also *New Hampshire Sta. Sci. Contrib.* 72 (1939), pp. 126-133).—In a study of factors which affect the cooking quality of potatoes, the authors believe that the number of samples of any lot should never be fewer than 50, but a reasonably accurate rating under almost any uniform condition should be possible with 100 tubers. The specific gravity test is thought to be a much more accurate measure of mealiness and cooking quality than can be obtained by subjective judging. The procedure which has been developed for determining specific gravity of potatoes by immersing them in salt solutions of varying concentration and classifying the tubers as having the same specific gravity as the solution in which they float is described, and comparisons of specific gravity with mealiness are reported for certain varieties grown in different parts of the State and of specific gravity with cooking quality for a single variety grown on different plats. In the majority of cases potatoes ranking from slightly mealy to very mealy had specific gravities from 1.08 to 1.1, while no samples classed as soggy or waxy had a higher specific gravity than 1.07. Potatoes judged excellent in cooking quality were all in the groups having sp. gr. 1.09, 1.1, and 1.105. In quality rating samples having an average sp. gr. 1.093 were given a quality rating of 93.

Specific gravity tests applied to several varieties grown in two localities gave comparable readings for a single variety. The order of quality rating of 5 out of 7 varieties was the same in the two localities, although the actual values were lower in all instances in the samples from one locality than those from the other. The varieties tested, with their quality ratings, were Green Mountain 94 (Colebrook) and 82 (Chichester), Smooth Rural 89 and 75, Russet Rural 84 and 81, Cobbler 83 and 73, Warba 81 and 71, Chippewa 79 and 65, and White Rose 71 and 60, respectively.

Adhesion of potato-tissue cells as influenced by pectic solvents and precipitants, C. J. PERSONIUS and P. F. SHARP. (Cornell Univ.). (*Food Res.*, 4 (1939), No. 3, pp. 299-307, figs. 4).—In continuation of the series of studies on potato tuber tissues (E. S. R., 81, pp. 591, 592), this paper records the results of attempts to produce by chemical means a softening of the tissues similar to that obtained in cooking. Comparable samples of potato tissue were placed in beakers containing various reagents and kept in a thermostatically controlled electric oven at 65° C., and samples were removed from time to time for tensile strength measurements. The pH of each solution was determined electrometrically. The reagents used included lactic acid in solutions of varying pH and a number of salts. The potatoes were for the most part tubers which had been in storage at 4.4° (40° F.) for at least 4 mo.

Under the conditions of the experiment extensive decreases in cell adhesion took place in solutions of ammonium oxalate, sodium citrate, and sodium fluoride and in lactic acid solutions having a pH of 3 or less. Definite but less extensive decreases in cell adhesion also took place in samples held in water, potato juice, and 0.2 N solutions of sodium or potassium chloride, and little or no decrease in solutions of 0.2 N barium, calcium, magnesium, or strontium chlorides. These results are thought to support the belief that the

intercellular cementing material of potato tissue is pectic in nature, and that doneness in potatoes is attained when the material has been weakened to the point at which the tissue cells can be separated readily. Samples held in 0.2 N solutions of aluminum, cupric, or ferric chlorides also showed decided decreases in cell adhesion, but this was attributed to the acidity of the solutions rather than to any effect of the cation. Further evidence that the softening of the tissues was due to the removal of calcium from its combination with the intercellular cementing material in the tissue or the formation of soluble salts was obtained by reversing the reaction by treatment of the softened tissues with calcium chloride solutions.

The results have not yet been duplicated with new or immature potatoes or with potatoes stored at temperatures other than 4.4° C. or for periods shorter than 4 mo. This is thought to suggest that the changes in the nature and amount of pectic substances in the potato during maturing and storage play an important part in the cooking qualities of potatoes and also that the cation content of the potato itself and the water in which it is cooked play an important part.

Oxalates in pineapples, H. E. CLARK. (Hawaii. Pineapple Prod. Expt. Sta.). (*Food Res.*, 4 (1939), No. 1, pp. 75-79).—This paper is devoted chiefly to a discussion of the difficulties encountered in attempts to determine accurately the oxalic acid content of pineapple juice. Quantitative recoveries of oxalic acid from water solutions containing graded amounts of the material were obtained only with concentrations equivalent to 0.024 percent or more of the fresh tissue. One sample of pineapples of the Cayenne variety, which is most widely grown in the Hawaiian Islands, gave a value of 0.008 percent. All others fell below 0.005 percent. It is concluded that the exact determination of the oxalic acid present must await the development of a reliable micromethod accurate for very small concentrations. However, it is considered that the concentration is so low that it has no physiological importance in human nutrition.

Nutritional and health values of frozen desserts, W. H. E. REM. (Univ. Mo.). (*Ice Cream Trade Jour.*, 35 (1939), No. 2, pp. 20, 40, 42, 55).—This is a nontechnical discussion of the food value, purity, and palatability of ice cream manufactured and merchandised by modern methods. Attention is called to the importance of serving ice cream at a temperature which best brings out the texture and flavor. This is considered to be at about 12°-14° F.

Sanitary condition of paper containers for retail packaging of perishable foods, J. R. SANBORN. (N. Y. State Expt. Sta.). (*Amer. Jour. Pub. Health*, 29 (1939), No. 5, pp. 439-442).—The importance of using clean sanitary paperboard and efficient methods of moisture proofing in the manufacture of containers for perishable foods is shown by comparisons of the bacterial counts per gram of disintegrated paperboard of virgin stock and of secondary stock, of the original paperboard and the finished containers, of containers paraffined at different temperatures, and of various paperboards and the finished containers made from them. It is noted that recently marked improvements have taken place in the bacteriological condition of both paperboard and finished containers as a result of effective programs of cleanliness and microbiological control at pulp and paper mills and container factories.

Quick freeze new quality preservative, J. A. CAMPBELL (*Miss. Farm Res. [Mississippi Sta.]*, 2 (1939), No. 6, p. 8).—A brief description is given of methods of preparing vegetables for frozen storage, with a list of suitable varieties of snap beans, lima beans, and peas commonly grown in the State.

Report by the Technical Commission on Nutrition on the work of its third session held in London from November 15th to 20th, 1937 (*League*

Nations Health Organ. Bul., 7 (1938), No. 3, pp. 460-502).—In the introduction to this report, progress which has been made in the study of the various nutritional problems noted in the previous report (*E. S. R.*, 75, p. 133) as needing further study is summarized. "Proximate and provisional" recommendations representing the consensus of opinion of the Commission are then given for human requirements of calcium, phosphorus, iron, and iodine; vitamins A, B₁, B₂ (limited to pellagra-preventive vitamin), C, and D; proteins and fats; and the nutritional requirements during the first year of life. This section is followed by sections dealing with the nutritive value of milk, methods of conducting nutrition surveys and of assessing the state of nutrition in infants and adolescents, nutrition problems of the Far East, and studies of nutrition in Chile.

Farm family diets in the Lower Coastal Plains of South Carolina, A. M. MOSEK (*South Carolina Sta. Bul.* 319 (1939), pp. 80, figs. 4).—Essentially the same plan was followed as in an earlier study of the Piedmont section (*E. S. R.*, 73, p. 557). A total of 214 weekly records of foods eaten by white farm families and 183 similar records for Negro families in three counties representing three types of farming areas in the Lower Coastal Plains was obtained in even distribution throughout the year. The average per capita quantities of the principal foods or groups of foods were calculated in the diets classified by food cost levels and by seasons of the year. Estimates were made of the nutritive value of the diets and from these the diets were grouped according to the same standards as used in the earlier study. In the case of vitamins A and C it was considered that the earlier standards were somewhat low and consequently estimates were also made on the basis of 4,000 and 6,000 International Units of vitamin A and 1,500 I. C. of vitamin C for the adult male.

In the presentation of the material attention has been paid to its use by different groups of readers. Part 1 consists of a brief section giving the general plan of the study and the results in terms of diet patterns, with the data presented graphically in weekly per capita consumption of different groups of foods in the A, B, and C diets of the white families and in all of the diets of the Negro families. The frequency by season of diets low in each of several nutritive essentials is similarly presented. Data on the extent of home production of foods and suggestions for improved diets on low country farms are also included in this section. Part 2 consists of the detailed report of the study as to scope and methods and with the results discussed under character, nutritive content, and money values of the diets. An appendix contains all of the tabular material, together with sample menus for the four seasons of the white and Negro families.

The average good or A diet among the white families had greater quantities of milk, potatoes, green leafy and yellow vegetables, tomatoes, and citrus fruits and lean meats, poultry, and fish than the average fair B or poor C diet. The C diets were higher in cereal products and in fats and fatty foods and had more lean meat, poultry, and fish than is usually considered necessary for for well-balanced diet. The pattern of the average Negro diet had many of the characteristics of the poor diets of the white families, although the consumption of milk, cheese, etc., exceeded the average C diet of the white families, of potatoes the B and C diets, of dried legumes and nuts all of the diets, and of leafy green and yellow vegetables the B diets of the white families. About 60 percent of the diets of the Negro families represented such low money value that good diets were practically impossible. Only 31 of the 214 records from white families fell in the group of weekly per capita money value of 62 ct.-\$1.23, while 94 of the 183 records from Negro families were in this group and there were 2 records of less than 62 ct. per week.

In comparison with the Piedmont section the diets of the Coastal Plains farm families at a given cost level contained almost twice as much lean meat, poultry, and fish and not over half as much milk. Other characteristic features of the Coastal Plains diets were the relatively large amounts of rice and the more liberal quantities of fish and sea food at all levels. It is concluded that the supplements needed for improvement of the typical Coastal Plains diet can best be secured by increased consumption of milk, vegetables, and fruit. A possible prolongation of the sweetpotato season, provision of a steady supply of green leafy vegetables throughout the year, the greater use of eggs, dried field peas, lightly milled or whole grain cereals, and home-made sirup, and more fresh or canned tomatoes, raw fruits, and raw vegetables are recommended as measures of improving the typical restricted diet at a small increased outlay of time, effort, and money.

Another good old southern custom receives complete vindication, O. SHEETS (*Miss. Farm Res. [Mississippi Sta.]*, 2 (1939), No. 2, p. 3).—The custom referred to is the use of hot biscuits and "molasses," and the vindication the high mineral, particularly iron, content of the unrefined sorghum and sugarcane sirups produced extensively in the State.

Plan family diet around the need of growing girls for variety, iron-rich food, D. DICKINS and O. SHEETS (*Miss. Farm Res. [Mississippi Sta.]*, 2 (1939), No. 4, pp. 1, 8).—Based on the results of an earlier survey of the food consumption of boys and girls in agricultural high school dormitories in the State (*E. S. R.*, 66, p. 193) and preliminary blood studies made in 1938 on 260 girls and 110 boys shortly after enrolling in college, the conclusion is drawn that the girls are more often below standard in various nutrients, particularly iron, than the boys. It is suggested that the family diet be planned around the needs of the girls, relying upon additional amounts of bread, cereals, sweets, and fats for the additional energy requirements of the boy.

The biological value of the proteins of rice and its by-products, M. C. KIK. (*Univ. Ark.*). (*Cereal Chem.*, 16 (1939), No. 3, pp. 441-447).—Polished rice was compared with whole rice and rice bran with rice polish by the modified paired feeding method of Mitchell, Burroughs, and Beadles (*E. S. R.*, 76, p. 879), using a nitrogen-free ration in combination with the protein ration to equalize weight gains. Nine pairs of rats were used for each comparison. In every instance the whole rice-fed rats utilized their food better than the paired animals fed polished rice, and those fed rice polish than those receiving rice bran. The differences were in all cases significant. One gm. of nitrogen from the whole rice ration was as effective for maintenance and growth as an average of 1.08 gm. from the polished rice ration and 1 gm. of nitrogen from the rice polish ration as effective as 1.2 gm. from the rice bran ration. The average gains in weight per gram of protein were 1.8 and 1.66 gm. for whole rice and polished rice and 1.79 and 1.48 gm. for rice polishings and rice bran. The biological values at a 5 percent level of protein were whole rice 72.7, polished rice 66.6, rice bran 84.9, rice polishings 82.9, and casein 81.5, respectively. At an 8 percent protein level rice polishings gave a value of 78.9 and rice bran 71.9 in comparison with whole milk powder 85.6, skim milk powder 87.8, casein 69.5, and lactalbumin 84.

The utilization of the calcium in various greens, M. SPEIRS. (*Ga. Expt. Sta.*). (*Jour. Nutr.*, 17 (1939), No. 6, pp. 557-564).—The procedure followed in the experiments reported was similar to that developed by Fincke and Sherman (*E. S. R.*, 76, p. 129) and consisted essentially in comparing the utilization of calcium by from 3 to 6 young rats placed at weaning on diets in which practically all of the calcium was furnished by skim milk powder with that of

matched animals receiving the same diet with half of the calcium of the milk powder substituted by that of dried greens. At 60 days of age the animals were killed and their entire bodies, minus the intestinal tract, analyzed for calcium.

The utilization factor for calcium, expressed as the ratio of calcium retained to that ingested, was on the control diet in which skim milk furnished all of the calcium 0.8 ± 0.05 for males and 0.78 ± 0.06 for females. On the other diets the utilization factor decreased in the order turnip greens, tendergreens, kale, collards, and New Zealand spinach for the males. For the females the value for collards was higher than for kale. With all of the greens except New Zealand spinach the values were within a range of 0.77 ± 0.03 for turnip greens (male rats) to 0.66 ± 0.04 for kale (female rats). The New Zealand spinach gave values of 0.14 ± 0.08 for males and 0.21 ± 0.1 for females. These very low values are considered to indicate that not only the calcium in the New Zealand spinach but probably some of that of the milk was rendered inactive by oxalate.

The influence of different levels of milk intake on the acid-base mineral balances of children, H. A. HUNSCHER, F. C. HUMMEL, and I. G. MACY (*Jour. Nutr.*, 17 (1939), No. 5, pp. 461-471).—This paper reports a series of nitrogen and acid-base balances for seven healthy children from 5 to 10 yr. of age over 715 experimental days, during which they were consuming 400, 600, 800, or 1,000 gm. of milk daily in addition to basal diets composed of 21 common foods easily obtained throughout the year. For the different subjects the diet was kept constant in quality of the mixed foods, but adjusted in quantity to meet individual physiological needs. The average daily intake of the various nutrients on the basal diet, including 400 gm. of milk, amounted to 1,676 calories, approximately 70 gm. of fat, 212 of carbohydrate, 57.35 of protein, 0.91 of calcium, and 1.25 gm. of phosphorus. At this level of milk, the average excess of base over acid in the food intake was 0.6 milliequivalent per kilogram per day (6 cc. 0.1 N alkali) and the range 0.5-0.7 m. e. per kilogram. When the milk was increased to 1,000 gm., the average excess of base over acid in the intake increased to 1.6 m. e. per kilogram per day.

All of the children stored both acid and base at all levels of milk intake, but the quantities stored were greater on the higher than the lower levels. The mean daily balance of excess base for all of the subjects on the 400-gm. intake was 0.2 m. e. (2 cc. 0.1 N base) per kilogram of body weight as contrasted with 0.9 m. e. (9 cc. 0.1 N base) during the daily ingestion of 1,000 gm. of milk. The urine, which constituted the major outlet of both acid and base, at all times contained an excess of acid over base, and the feces more base than acid, this increasing with higher levels of milk.

All of the children gained in recumbent length and in weight, but the amounts of these gains appeared to have no direct relationship to the quantity of excess base stored. The retentions of nitrogen were positive at all milk levels, ranging from 2.1 to 40.4 mg. per kilogram of body weight daily on the 400-gm. level to from 46 to 60.7 mg. on the 1,000-gm. level. "These results indicate that neither the recumbent length, the weight gains, nor the excess base balance alone give an index to the type of chemical growth that is taking place. The retention of nitrogen is a more exact measure of growth than is the increase in weight, which may be due in a varying degree to body water or fat. . . . With the changes to higher levels of milk intake the increased calcium:phosphorus ratios indicate gains in rate of synthesis of skeletal tissue over the rate of soft tissue construction, and bear out the fact that the kind of chemical growth accruing at any particular time is characteristic of the individual child with his peculiar inherent physiologic needs in response to the growth impulse as well as to the type and quantity of food that he consumes."

Adequacy of cow milk as a source of magnesium for rats, H. G. DAY and E. ORENT-KEILS (*Soc. Expt. Biol. and Med. Proc.*, 40 (1939), No. 4, pp. 638-640).—This study was undertaken as a result of a report by Duncan et al. (*El. S. R.*, 73, p. 673) that the nutritional failure of calves on a milk diet supplemented only by iron, copper, and manganese is due to a failure in the magnesium metabolism. No symptoms suggestive of magnesium deficiencies were observed in rats fed as long as 74 days on a diet of pasteurized grade A milk ad libitum supplemented with 0.25 mg. of thiamin per liter and with adequate supplements of manganese, iron, and copper. No difference could be detected in growth and in serum content of magnesium between this group and a group receiving supplements of magnesium in amounts doubling the magnesium content of the milk. Analyses of the bones of the rats on the diets without added magnesium, when sacrificed at 56 and 74 days, showed no decrease in the magnesium content as a result of continued use of the unsupplemented milk. It is concluded that cow's milk contains enough magnesium to prevent magnesium deficiency in rats.

Some effects of low choline diets, W. H. GRIFFITH and N. J. WADE (*Soc. Expt. Biol. and Med. Proc.*, 41 (1939), No. 1, pp. 188-190).—In this preliminary report a newly recognized effect of choline deficiency in the diets of rats is described. The basal diet consisted of fibrin 4 parts, casein 8, dried egg white 3, salt mixture 4, calcium carbonate 1, cod-liver oil 5, lard 35, agar 2, and sucrose 38 parts supplemented with thiamin chloride, riboflavin, nicotinic acid, and concentrated extracts of rice polish and hog liver. In animals killed and examined at the end of a 10-day experimental period, 90 percent showed marked hemorrhagic kidneys, as well as fatty livers previously demonstrated by Best and Channon (*El. S. R.*, 76, p. 571). All of the rats on the low choline diet were noticeably sick, the spleen was enlarged, and the thymus decreased to about half its normal weight. On microscopic examination the kidney tissue showed extensive glomerular and tubular degeneration, with hemorrhagic areas in the cortical region particularly. The damage to the kidneys was the same whether the vitamin supplements were omitted, fed separately, mixed with the diet, or doubled in amount. The degeneration was prevented when 2 mg. of choline was fed, although this amount had no effect on the liver fat. Ten mg. of the choline was required daily to prevent the fatty liver. Typical fatty livers and hemorrhagic kidneys occurred on a diet in which the lard was decreased from 35 to 15 percent. The condition was severe when all of the dietary protein was supplied by fibrin. The livers were fatty but the kidneys normal when all of the protein consisted of casein or egg white alone.

Prothrombin concentration in newborn, A. J. QUICK and A. M. GROSSMAN (*Soc. Expt. Biol. and Med. Proc.*, 41 (1939), No. 1, pp. 227, 228).—In this preliminary report attention is called to a profound fluctuation in the prothrombin content of the blood of infants in the first 48 hr. Six hr. after birth the level is relatively high and not very different from that of cord blood. By the end of the twenty-fourth hour the values may drop to exceedingly low levels and begin to return to normal at about the forty-eighth hour. This is thought to explain the frequency of hemorrhagic disease in the newborn infant. The infant is born with no reserves of prothrombin and during the first 24 hr. the supply of the factor may be reduced to dangerous levels. The response of the hemorrhagic disease to vitamin K, as shown by Waddell et al. (*El. S. R.*, 81, p. 600), indicates that deficiency of the factor is the cause of the hemorrhagic condition. The abrupt recovery of prothrombin in 48 hr. cannot be attributed to vitamin K in the food supply. The fact that vitamin K can be produced by bacterial action is thought to suggest that with the establishment of an intesti-

nal flora in the infant following the ingestion of food and water "the synthesis of vitamin K begins, which, with the aid of bile, is absorbed, thus ending the danger of bleeding due to prothrombin deficiency."

A method for estimating the degree of mineralization of bones from tracings of roentgenograms, P. B. MACK, A. T. O'BRIEN, J. M. SMITH, and A. W. BAUMAN. (Pa. Expt. Sta.). (*Science*, 89 (1939), No. 2316, p. 467, fig. 1).—The method described consists in tracing by means of a modified recording microphotometer the density of a roentgenogram of the bone from one fixed point to another. "The modification of the original apparatus has consisted in substituting a photronic cell for the thermopile originally in the instrument to obtain greater sensitivity and quicker response, in introducing a means of regulating the current through the light source, in providing for the continuous recharging of a storage battery in the circuit of the light source, and in introducing resistance into the galvanometer circuit sufficient to give critical damping."

The apparatus is illustrated by a diagram, and the method of using it is described in detail. The instrument is being used to make tracings of roentgenograms of both bones and teeth by means of planimeter measurements. Comparative densities of different sections of the same bone or of the same tooth may be found, densities of similar sections of certain bones or teeth of different individuals may be compared, and density values may be calculated in terms of units of a density ladder of known mineral composition.

The diagnostic significance of changes in the red cells, R. L. HADEN (*Bul. N. Y. Acad. Med.*, 2. ser., 15 (1939), No. 5, pp. 291-310, figs. 11).—Of particular value in this discussion is a series of charts illustrating the text. These include diagrams of the normal erythron showing the relative volumes of its constituents; the function of the red cells as hemoglobin-filled cups on an endless chain conveyor which continually takes up oxygen from the lungs and gives it up in the tissues; the relative volumes of total blood and circulating erythron under normal conditions (men and women) and in various types of anemia; the physiology of the normal red blood cell in its formation, circulation, and destruction; the measurement of the red cell with values for the different determinations in the normal man; the distribution curves in percentages of cells, cell diameters, and cell volumes of the red cell under normal conditions, in microcytic and hypochromic anemia, and in pernicious anemia; types of anemia represented as varying kinds of endless chain conveyors; anemias due to increased blood loss and decreased blood formation in relative values for the different blood cell measurements; and the changes in the red blood cells in pernicious anemia with adequate liver therapy and in iron deficiency anemia with adequate iron therapy.

A comparison of indices used in judging the physical fitness of school children, S. P. SOUTHER, M. M. ELIOT, and R. M. JENSS (*Amer. Jour. Pub. Health*, 29 (1939), No. 5, pp. 434-438).—This preliminary report of an investigation undertaken to compare various procedures used in evaluating the health of children deals with a limited aspect of the problem, namely, the ability of each of four indices of body build to identify children who are likely to be considered physically unfit as judged by the ratings of the physician concerning the child's general nutrition and by the child's annual rate of gain in weight. The indices selected were the Baldwin-Wood height-weight index, the Pryor width-weight, and the Franzen ACH and nutritional status indices. The subjects were 713 7-year-old white boys and girls living in New Haven, Conn.

The physician who examined the children classified 40 of the 348 girls as poorly nourished. Of these 63 percent were underweight according to the

Baldwin-Wood index and 28 percent by the Pryor index. With the Franzen ACH index 10 percent of the 40 were classified as below par, with the weight index 3 percent and with the indices of arm girth and subcutaneous tissue 5 percent. In the comparison of the annual gains in weight with the classifications by the various indices, the lowest 10 percent of the group according to gains in weight was considered. Of these only 29 percent showed agreement by the Baldwin-Wood index and none by the Franzen nutritional status index. Similar analyses of the findings for the boys showed a like degree of failure in identifying by any of these indices the boys whom the physician considered poorly nourished or whose weight gains were markedly below average.

It is concluded that for the present "the clinical examination must certainly form an integral part of the assessment, especially if determining the need of medical care is to be one of the objectives of a school health program. On the other hand, a great deal can be done to improve the clinical examination and to make the physician's judgment more stable and objective. Provision must also be made for observing the child at regular intervals so that his physical condition can be evaluated in terms of his own previous growth and health. Until the physician is furnished with more satisfactory and practical tools for evaluating the child's physical fitness, it may also be wise to supplement the clinical examination with some simple measure of the child's progress, such as his relative gain in weight."

Basal metabolism of 38 American-born male Japanese university students, F. M. BALDWIN and C. K. FUJISAKI (*Soc. Expt. Biol. and Med. Proc.*, 41 (1939), No. 1, pp. 41-44).—The average basal metabolic rate, measured indirectly with a Sanborn apparatus, of 38 American-born male Japanese university students in California was -3.4 percent according to the Harris-Benedict and -4.1 percent according to the Aub-DuBois prediction standards. It is noted that these results are in excellent agreement with those reported by Miller and Benedict (*El. S. R.*, 77, p. 420) for Hawaiian-born Japanese high school and college students in Hawaii and by Okada et al. in an earlier study of 42 medical students in Japan. The values in the three studies were within the range of 4 percent. This close agreement for like subjects of the same race in three geographical localities is thought to support the belief that "racial characteristics are retained hereditarily as far as the basal metabolism of Japanese is concerned."

A study of the dietary and value of living of 44 Japanese families in Hawaii, C. D. MILLER (*Hawaii Univ. Res. Pubs. No. 18* (1938), pp. [2]+27).—Thirty-six of the families lived in Honolulu, the others being rural families on the Island of Hawaii. Data on income and value of living for 1 yr. were obtained on schedules based upon the forms of the U. S. D. A. Bureau of Home Economics, and the schedules and itemized records kept by a member of each family for 4 consecutive weeks were used for the diet calculations. The average size of the family was 5.7 persons, and the incomes of individual families ranged from \$723 to \$3,227 per year, with an average of \$1,910. Food expenditures constituted 30 percent, housing 12.7, clothing 14.5, household operation 9.1, formal education 6.6, automobile 5.9, medical and dental 5.4, recreation 4.3, gifts 2.9, personal care 2.8, furnishings and equipment 2.6, other transportation 2, community welfare 1.1, and other items 0.1 percent.

The nutritive value of the diets was studied (1) by comparing the quantity of certain nutritive constituents of the diet with standards used in the United States and Japan, (2) by calculating the distribution of calories among the common food groups, and (3) by comparing the quantities of different foods or groups of foods consumed with similar data for the mainland United States.

According to American standards, there was no serious deficiency of calories, protein, phosphorus or iron except for a few families, but there were deficiencies in calcium and in vitamins A and B in all but a few of the diets. About 60 percent of the calories came from cereals (almost 48 percent from rice) as compared with 74 percent for Japanese families in Japan and 38 percent for American families in the United States. The proportion of calories coming from animal protein was about half that of American families, but greater than for Japanese families in Japan. The proportion of calories from milk (4.9 percent) was much higher than that of Japanese families in Japan (0.4 percent). The proportion of calories derived from fruits was the same (3 percent) as for American families and more than 3 times as much as that of Japanese families in Japan. Japanese families in Hawaii and Japan both obtained about the same percentage of their calories from vegetables, approximately the same legume and legume products, and approximately the same percentage from sugar and sweets. The vegetable consumption was about half that of American families and the consumption of sugar and sweets about 3 percent less than the average for American families. The fat consumption was about twice that of Japanese families in Japan and about half that of American families.

In terms of per capita consumption of different foods the families in the present study showed a very high consumption of white rice in comparison with the United States, only from one-fourth to one-half the consumption of potatoes, and a higher consumption of tomatoes, citrus fruits, and of vegetables other than potatoes. The average consumption of milk, ice cream, and cheese was approximately half that of average American families and of lean meat, fish, eggs, and poultry about the same. Less butter and other fats were consumed.

Basal heat loss and production in women at temperatures from 23° C. to 36° C., J. D. HARDY and A. T. MILHORAT. (Cornell Univ.). (*Soc. Expt. Biol. and Med. Proc.*, 41 (1939), No. 1, pp. 94-98, figs. 2).—In this preliminary report data are summarized on an extension to three normal women of previously reported studies of the effect of environmental temperature on heat loss in nude male subjects (E. S. R., 80, p. 558). Rectal temperatures at 24° were about 0.15° lower than at 36°. The average skin temperature increased linearly with the calorimeter temperature between 23° and 33° and did not change with further increase in calorimeter temperature. Heat loss decreased linearly up to a calorimeter temperature of 31°, and after reaching a low point of 29 calories per square meter per hour at 32° rose slowly with higher temperature. Heat production was constant at 35 calories per square meter per hour between 23° and 27°, at 28° began to decrease slowly, and at 32°-33° reached a low production of 29 calories per square meter per hour. At this point the heat production equaled and from then on followed closely the heat loss. Vaporization was practically constant between 23° and 32°, at which point sweating began. The conduction of the peripheral tissues was almost constant between 23° and 28.5°, with a value corresponding to a tissue thickness of 22 mm. and increased linearly with the temperature from this point to 36°. The cooling constant of Newton's law was constant at 5.3 calories per square meter per hour. A graphic comparison of the findings in this study with those of the male subjects in the earlier study shows identical rectal temperatures and cooling constants but significant differences in the other responses to temperature changes. The skin temperature of women was higher in the warm atmosphere and lower in the cold than that of the men, the threshold temperature for sweating was 2° higher, and the heat production above a temperature of 27.5° was lower than that of the men.

The effect of apple constituents on the retention by growing rats of lead contained in spray residues, J. B. SHIELDS, H. H. MITCHELL, and W. A. RUTH. (Univ. Ill.). (*Jour. Nutr.*, 18 (1939), No. 1, pp. 87-97).—Twelve groups of three newly weaned rats each were fed three diets of like composition except as follows: Diet No. 1 contained no apple powder but its equivalent in starch and agar, diet No. 2 32 percent of apple powder from unsprayed apples, and diet No. 3 32 percent of apple powder from fruits sprayed with lead arsenate. Diets Nos. 1 and 2 contained the same quantity, 54 p. p. m., of lead arsenate furnished by the apple powder in diet No. 3. The lead content of the three diets amounted to 33 p. p. m., the calcium content 0.54, 0.51, and 0.51 percent, and the phosphorus content 0.63, 0.66, and 0.66 percent, respectively. The three diets were fed in equal amounts daily within each trio, but the weights of the trio were kept the same by feeding sugar in concentrated solution to the animals growing at the slower rates. Particular care was taken that no contact with lead was possible. With nine groups the experiments were terminated after 1 kg. of the diet had been consumed and the others after the consumption of 723, 650, and 750 gm. At the end of the period the rats were killed, their body lengths measured, and the carcasses minus the alimentary tract analyzed for lead by the colorimetric diphenylthiocarbazone method. Check rats from each of the litters used were killed at the beginning of the experiment for determining the initial content of lead, the average figure for which was established at 0.046 mg.

The average lead retentions on the three diets were 0.536, 0.345, and 0.329 mg., respectively, equivalent to from 1 to 1.5 percent of the lead ingested. The differences between the retentions on diets 2 and 3 were not statistically significant, showing that the lead contained in the spray residue was as readily absorbed and retained as in the original spray material. The differences between the retentions on diets 1 and 2 and on 1 and 3 were significant, showing that the rats stored less lead in the presence than in the absence of the apple powder. The difference amounted to 37 percent under conditions in which the lead was present in amounts of 96 p. p. m. of the apple solids as compared with 22 p. p. m. in apples containing no more lead than the legal tolerance. The demonstration that the apple contains within its tissues a substance or substances (probably pectic constituents) that exerts a considerable effect on the intestinal absorbability of the lead component in spray residues is thought to suggest that in feeding experiments concerned with the possible toxicity of lead in lead arsenate spray residues on fruits, rations containing the fruit solids should be used unless it can be shown that the fruit itself does not modify the assimilability of the lead.

Effect of avitaminosis A on the human blood picture, O. D. ABBOTT, C. F. AHMANN, and M. R. OVERSTREET. (Fla. Expt. Sta.). (*Amer. Jour. Physiol.*, 126 (1939), No. 2, pp. 254-260, figs. 3).—The method described for detecting vitamin A deficiency in rats by differential leucocyte count (*E. S. R.*, 80, p. 852) has been tested on human beings with consistent results. The subjects, 157 in all, consisted of college students and rural school children whose diets had been habitually low in vitamin A and women who, because of overweight, had been subsisting on diets restricted in calories and consequently quantitatively low in vitamin A. All showed symptoms of vitamin A deficiency in loss of vigor, general weakness, dry hair and skin with desquamated areas, and eye defects varying from burning and redness of the lids to well-defined conjunctivitis, including in a few cases actual involvement of the cornea. Blood tests were made before and at 10-day intervals during treatment with 51,000 U. S. P. units of vitamin A daily. The characteristic changes from normal in this blood

picture were a mild leucopenia, a decrease in the polymorphonuclear neutrophils, a relative increase in large lymphocytes with a corresponding drop in small lymphocytes, the occurrence of degenerative cells, and an increase in the number of juveniles. "It will be noted that this blood picture is similar to that of rats fed a diet deficient in vitamin A and, as in the case of the rats, the administration of large amounts of vitamin A brought about a gradual improvement in symptoms and in a few weeks the differential count was within the normal range. From this work it was concluded that the differential leucocyte count is of value in diagnosing a deficiency of vitamin A in man."

Effect of pectin supplements on avitaminosis A in rats, A. KOBREN, C. R. FELLEBS, and W. B. ESSELEN, JR. (Mass. Expt. Sta.). (*Soc. Expt. Biol. and Med. Proc.*, 41 (1939), No. 1, pp. 117, 118).—The possibility that pectin through its galacturonic acid composition might retard the keratinization of the mucous membranes characteristic of vitamin A deficiency was tested on three groups of rats fed a vitamin A-free diet plus 3, 6, and 12 percent of pectin. In comparison with controls on the deficient diet alone the pectin-fed animals showed no delay in the onset of xerophthalmia. Histological sections of various mucous membranes in the animals sacrificed at the first appearance of xerophthalmia in any of the animals in the group showed marked changes in mucous membranes and submucous coat of the vagina, nares, and eyelids of all of the animals on the deficient diet but somewhat less marked in those receiving pectin.

Vitamin interrelationships.—I, Influence of avitaminosis on ascorbic acid content of various tissues and endocrines, B. SURE, R. M. THEIS, and R. T. HARRELSON. (Univ. Ark.). (*Jour. Biol. Chem.*, 129 (1939), No. 1, pp. 245-253).—Data are summarized from an extensive series of studies of the ascorbic acid content of various tissues and endocrine glands of rats which had undergone single and repeated depletions of vitamin B₁ and of vitamin A and single depletions of riboflavin and of vitamin B₂ in comparison with normally fed and fasting control animals. Fasting for as long as 10 to 11 days and the ingestion of from 4 to 16 mg. of ascorbic acid per day by rats on a satisfactory diet brought about no change in the concentration of ascorbic acid in the organs and tissues examined. In vitamin B₁ deficiency the lungs showed decreases in ascorbic acid amounting to 35 percent, kidneys 23, and livers 19 percent. Repeated depletions produced additional heavy losses. The only significant change in the endocrines was a decrease of 27.8 percent in the ascorbic acid content of the thymus. In vitamin A deficiency decreases in ascorbic acid content were noted amounting to 20 percent in the heart, 27.3 in the kidney, and 24.1 percent in the thymus. As only four groups were examined for the kidney and thymus, the results of these organs were not considered conclusive. In multiple vitamin A depletions with from 12 to 16 groups of animals available decreases were found amounting to 26.6 percent for the kidneys, 45 for the livers, 19.2 for the thymus, and 12.4 percent for the adrenals. In 7 groups in which the pituitaries and 5 in which the thyroids were studied, losses of ascorbic acid amounting to 25.8 and 15.3 percent, respectively, were found. In single depletions of riboflavin the ascorbic acid losses amounted to 44.4 percent for the liver, 45.4 for the kidney, 41.2 for the lung, 85.7 for the thymus, and 20.7 percent for the thyroid. No changes were observed in the adrenals or pituitary. No noteworthy changes in the ascorbic acid content of tissues or endocrines were found in vitamin B₂ deficiency.

The data are thought of significance in suggesting that a deficiency in one vitamin in human nutrition may be responsible for exhaustions of the reserves of other vitamins. "Findings of this nature should be taken into consideration

by practicing physicians and clinicians in their daily experiences with vitamin therapy."

The correlation between vitamin B₁ and vitamin C [trans. title], M. KASAHARA, Y. NISHIZAWA, and S. HIRAO (*Klin. Wchnschr.*, 18 (1939), No. 7, pp. 246-248, figs. 5).—Guinea pigs, rats, and pigeons were used as test animals. Tooth response, growth rates, and recovery from polyneuritis, respectively, were the factors studied. The authors considered that the antineuritic action of vitamin B₁ was enhanced and that its growth-promoting effect was influenced by simultaneous administration of vitamin C. Vitamin B₁ was thought to exert a protective effect on scorbutic guinea pigs. These results were interpreted to indicate a synergistic action of vitamins B₁ and C.

Cereals as a source of vitamin B₁ in human diets, R. R. WILLIAMS (*Cereal Chem.*, 16 (1939), No. 3, pp. 301-309).—This paper, although written for the cereal chemist, is of general interest in the clear explanation it contains of the necessity of thiamin for carbohydrate metabolism and the significance of its practically complete removal from cereals in the refining processes. In the opinion of the author "carefully to sift the starch from the other parts of the seed and make the starchy endosperm the chief source of energy for human life is to fly in the face of Providence. . . . Only the producer of refined cane sugar can rival the miller of rice or wheat (the world's two largest cereal crops) in the thoroughness of the devitalizing purification process."

Whey as the substratum in vitamin B₁ assays, A. L. DANIELS (*Soc. Expt. Biol. and Med. Proc.*, 41 (1939), No. 1, pp. 235-240).—Comparable diets with autoclaved whey, autoclaved yeast, and autoclaved liver as the source of the various heat-stable vitamins of the vitamin B complex in vitamin B₁ assays by the method involving the use of the same animals in two or more assays have proved unreliable with the autoclaved whey. Instead of giving consistent results in successive periods in the amount of thiamin required for unit gain in weight, as was the case when autoclaved yeast or liver was used, the successive assays with whey required an increasingly large amount of thiamin for the same gains in weight. This is thought to indicate an inadequacy in autoclaved whey of a factor present in adequate amounts in autoclaved liver and yeast. The nature of the substance or substances has not been investigated, but the retarded growth without other obvious symptoms is thought to suggest that one component of factor W of Frost and Elvehjem (*El. S. R.*, 79, p. 137) is the substance in question. Attention is called to the failure of appetite in animals receiving the basal whey ration even with added B₁ as an indication that the unidentified factor as well as vitamin B₁ is concerned with appetite.

Determination of a curve of response to synthetic crystalline thiamin for use in the vitamin B₁ assay of foods by the rat-growth method, C. D. MILLER (Hawaii Expt. Sta.). (*Jour. Nutr.*, 17 (1939), No. 6, pp. 535-544, figs. 2).—Curves of response have been established for the growth rate of young rats equally distributed as to sex on graded doses of thiamin in addition to a basal thiamin-free ration over periods of 3 weeks and of 5 weeks. A total of 192 rats was given the basal diet at 21 days of age and at depletion of the thiamin stores in about 20 days. Twenty-five of the animals were used as negative controls, and the others were divided into groups of nearly even size and fed daily doses of synthetic crystalline thiamin at levels of 1, 2, 3, 4, 8, and 16 µg. daily. The results show a definite curvilinear relationship between the mean gains in weight and the quantities of thiamin administered, represented by the equation y (gain in weight) = $3.0 + 62.3 \log X$ (daily dose of thiamin) for the 3-week period, and $y = 9.2 + 94.9 \log X$ for the 5-week period.

With the exception of the group of rats receiving the 1- μ g. thiamin supplement for 3 weeks, all of the mean gains in weight for both periods were highly significant, with no advantage of the 5-week period over the 3-week period. By the analysis of variance method it was established that the number of animals that must be used with the colony in question to obtain reliable results in thiamin assays is 12 for the 3-week and 15 for the 5-week period. The 3-week period is consequently considered preferable from the standpoint of economy in the number of animals as well as in time.

Influence of the composition of the diet on the thiamin requirement of dogs, A. ARNOLD and C. A. ELVEHJEM. (Wis. Expt. Sta.). (*Amer. Jour. Physiol.*, 126 (1939), No. 2, pp. 289-298, figs. 5).—Vitamin B₁ requirement tests on dogs are reported, with results confirming observations on other species that the requirement for thiamin is best stated as percentage of the diet rather than in terms of body weight, and the conclusion of Williams and Spies that "all species of animals require somewhat less than 1 p. p. m. of thiamin in the food when carbohydrate predominates in the diet to the degree which is usual for most species." It was also shown that fat has a sparing action for vitamin B₁ and that with increased amounts of fat in the diet the requirement is correspondingly reduced.

The relation of dietary fat to the thiamin requirements of growing rats, F. E. STIRN, A. ARNOLD, and C. A. ELVEHJEM. (Wis. Expt. Sta.). (*Jour. Nutr.*, 17 (1939), No. 5, pp. 485-495, figs. 3).—The sparing action of fat for thiamin has been demonstrated by successive replacements of sucrose in the basal thiamin-free ration of Arnold and Elvehjem (E. S. R., 80, p. 562) by fats on an isocaloric level. When the sucrose was completely substituted by coconut oil after the rats had been depleted to the point of polyneuritis on the regular ration, the subsequent growth and improvement of polyneuritic symptoms were as good on the fat diet with no thiamin as on the sucrose diet with 15 μ g. of thiamin daily. The use of butterfat in place of coconut oil made no appreciable difference in the rate of growth. Controls fed the unsupplemented diet died at the end of the fourth week. Partial replacement of sucrose with fat gave results in proportion to the amount substituted. On the smallest amount of fat (7 percent) the polyneuritic symptoms were alleviated, but the recovery period was much longer and growth was poor. When the fat content was 26.2 percent and the sucrose 20.1 percent nearly as good results were obtained as when the fat entirely replaced the sucrose and constituted 89.4 percent of the ration. Rats receiving a diet in which all of the sucrose was replaced by autoclaved fat recovered from polyneuritis in 3 days as compared with 5 hr. on the same diet supplemented with thiamin, but after the first week grew as rapidly as those receiving thiamin. The livers of rats which had been on the autoclaved fat diet without supplement for 3 weeks were found to have similar amounts of cocarboxylase in their livers as were found in polyneuritic rats and much less than rats on the normal diet. There was much less difference in the cocarboxylase content of the brains of the animals in the three groups. A series of trials with various natural fats, including peanut oil, lard, cod-liver oil, cottonseed oil, and also synthetic triacetin gave like responses as to growth, but slower response on some fats than others in the relief of polyneuritis. The fact that growth resulted in the presence of polyneuritic symptoms was thought to indicate that fats produce their effect independently of thiamin.

The results are discussed with reference to seemingly contradictory reports in the literature. The cocarboxylase values in the livers are considered of particular importance in indicating that, while the animals are unable to build up or maintain their thiamin reserves, they are still able to obtain energy for

growth purposes from the metabolism of fat. "In thiamin deficiency the rat preferentially metabolizes fat as opposed to carbohydrate. This wipes out the fat reserves. In the presence of thiamin the rat is able to metabolize carbohydrate normally both for energy and for fat synthesis which allows for an accumulation of fat."

The B vitamins and fat metabolism.—I, Effects of thiamine, riboflavin, and rice polish concentrate upon body fat; II, The effect of thiamine upon the synthesis of body fat in pigeons, E. W. McHENRY and G. GAVIN (*Jour. Biol. Chem.*, 125 (1938), No. 2, pp. 653-660, figs. 2; 128 (1939), No. 1, pp. 45-49).—In the first of these papers evidence is presented suggesting the production of fat from carbohydrate in the bodies of rats fed thiamin, as well as riboflavin and a rice polish concentrate, as a source of vitamin B₆. In the second a similar synthesis in pigeons is suggested through the demonstration of an increased content of crude fatty acid in pigeons receiving thiamin as the only supplement to a polished rice diet.

Nutritional significance of nicotinic acid, C. A. ELVEHJEM. (Univ. of Wis.), (*Collect. Net*, 14 (1939), No. 5, p. 109).—A brief account is given of the various steps leading to the separation of the antipellagra factor from the other vitamins of the B complex and its identification as nicotinic acid. It is noted that foods containing only fair amounts of nicotinic acid are useless in the treatment of pellagra because the pellagrin is unable to digest the food sufficiently to liberate the nicotinic acid present. It is emphasized, however, that nicotinic acid as such is an emergency measure, and that the goal should be such modifications of the diet as would enable the people in the areas in which it is now endemic to obtain sufficient nicotinic acid, as well as other essentials, from foods.

Effect of nicotinic acid deficiency on the cozymase content of tissues, A. E. AVELROD and C. A. ELVEHJEM. (Univ. Wis.). (*Nature [London]*, 143 (1939), No. 3616, pp. 281, 282).—It is noted briefly that in nicotinic acid-deficient dogs and pigs the blood shows no difference in cozymase before and after nicotinic acid therapy, and that the nicotinic acid-deficient dogs and pigs show no decrease in cozymase content of either brain or kidney from that of similar tissues of animals fed the basal diet plus nicotinic acid. The livers of the deficient animals show a decrease in nicotinic acid of about 100 percent and the muscles as high as 1,000 percent.

The polarized light method for the study of myelin degeneration as compared with the Marchi and Sudan III methods, C. O. PRICKETT and C. STEVENS. (Ala. Polytech. Inst.). (*Amer. Jour. Pathol.*, 15 (1939), No. 2, pp. 241-250, pls. 3).—The polarized light method, as recommended by Sutton et al. (*El. S. R.*, 73, p. 134), for demonstrating myelin degeneration due to transection of the peripheral nerves of the rat, was found to be rapid and accurate as compared with the Marchi method, which gave very inconsistent results, and the Sudan III method, which failed to detect the early changes following transection. One or two modifications of the Sutton technic were found to be advantageous. Reducing the thickness of the section from 20 μ to 10 μ gave clearer details. Uncrossing the analyzer prism was found advantageous "for determining the continuity of fibers which appear segmented, for distinguishing between edema of the axis cylinders and periaxillar accumulation of isotropic material, and for revealing the presence of isotropic fibers masked by the crossed Nicols."

The appearance of normal, and transected nerves under polarized light is described in considerable detail, with illustrative microphotographs.

Histopathology of the peripheral nerves in acute and chronic vitamin B₁₂ deficiency, C. O. PRICKETT, W. D. SALMON, and G. A. SCHRAEDER. (Ala. Poly-

tech. Inst.). (*Amer. Jour. Pathol.*, 15 (1939), No. 2, pp. 251-260, pls. 3).—The polarized light method, as described in the paper noted above, was used in a further study of the disputed question as to the production of myelin degeneration in the peripheral nerves of rats by vitamin B₁ deficiency. The same material was tested by the Sudan III method for comparison. Both acute and chronic vitamin B₁ deficiency was produced in rats, of which a total of 133 were used in the study of acute deficiency and 40 chronic deficiency. The first group was further divided into two groups of 63 animals on diets limited in calories to 12 per rat daily and 70 on corresponding diets fed ad libitum. Each of these groups was further subdivided into three subgroups receiving the vitamin B₁-deficient diet, the same diet plus vitamin B₁, and the stock diet. For the most part the animals were allowed to develop severe neuromuscular symptoms and were killed on an average of 25 days after the symptoms developed. Groups studied for chronic deficiency were maintained in this state by the administration of small doses of vitamin B₁ after the severe symptoms appeared. In this group two types of symptoms appeared following partial alleviation of the symptoms of acute deficiency. The first were typical of impaired equilibration and the second of a peculiar ataxic type of walk not often seen in the acute condition and developing in the more severe cases to partial or complete paralysis of one or both hind legs, with impairment of sensation in the affected extremities. These two types of symptoms were often present in the same animal, but in numerous instances one or the other of the symptoms appeared alone.

On autopsy the peripheral nerves of the animals in the deficient and control subgroups of the group being studied for acute deficiency showed no gross abnormalities. In the chronic deficiency group no abnormalities were visible on gross examination in most of the animals, but in a few that had shown severe symptoms localized enlargements were observed along the course of the peripheral nerves. When examined under polarized light the peripheral nerves of rats that had developed symptoms of acute deficiency showed a few fibers of Wallerian degeneration and mild edema. Both of these conditions were also shown by the control rats and by rats that had become moribund without developing typical neuromuscular symptoms. In the various groups the Wallerian degeneration increased in the order—acute deficient, controls, moribund without symptoms, and controls on adequate vitamin B₁ with limited food intake.

In the animals in which a state of chronic deficiency had been produced, marked changes were shown by the polarized light method but not by the Sudan III method. These changes consisted in greatly enlarged fibers in some cases, with large bulbous areas along their course and with increased amounts of isotropic material, the fibers becoming completely isotropic in the most severe cases. It is considered significant in view of these marked changes that a stage is eventually reached in the chronic deficiency when the symptoms cannot be cured even by the administration of relatively large doses of thiamin chloride, indicating irreparable damage to the tissues.

Effect of riboflavin-low diets upon nerves, growth, and reproduction in the rat. R. W. ENGEL and P. H. PHILLIPS. (*Wis. Expt. Sta.*). (*Soc. Expt. Biol. and Med. Proc.*, 40 (1939), No. 4, pp. 597, 598).—The severe nerve degeneration which the authors have shown to be characteristic of riboflavin deficiency in growing chicks (*E. S. R.*, 80, p. 673) could not be demonstrated in rats on a similar ration. The ration also had no adverse effect on reproduction but was not satisfactory for growth. No improvement was noted on the addition of nicotinic acid.

A study of rachitogenic diets composed of purified food materials, J. H. JONES (*Jour. Nutr.*, 17 (1939), No. 6, pp. 601-609, fig. 1).—Blood fibrin, previously noted as a satisfactory source of protein in synthetic diets for rats (E. S. R., 80, p. 274), has been used at an 18-percent level in a series of low phosphorus rickets-producing diets. Diet 570, which proved very successful, was composed of alcohol-extracted fibrin 18 percent, brewers' yeast 5, salt mixture No. 5 (consisting of NaCl 1, CaCO₃ 3, KCl 1, anhydrous MgSO₄ 0.2, ferric citrate 0.1, and KI 0.004 parts) 5.3, agar 2, carotene solution 0.1, and dextrinized starch 69.6 percent. In the other diets the changes from diet 570 consisted successively in replacing the dextrinized starch with sucrose (diet 573), omitting the yeast and agar, increasing the sucrose to 73.6 percent, and adding liver extract 1 percent, cellulose 2 percent, and thiamin 20 µg. daily (diet 610); omitting the agar and increasing the sucrose to 71.6 percent (diet 576); altering diet 610 slightly by adding 0.56 percent K₂HPO₄ and reducing the percentage of sucrose accordingly (diet 611); using alfalfa 2 percent in place of the agar and carotene of diet 570 (diet 618); and using in place of salt mixture No. 5 in diet 618 1 part of NaCl and 3 parts of CaCO₃ (diet 623). In one diet (No. 612) 12 percent of casein replaced the fibrin, the other constituents being salt No. 5 5.3, carotene 0.1, sucrose 78.8, liver extract 1, cellulose 2, and a yeast concentrate 0.8 percent. The phosphorus content of these diets in the order described was 0.08, 0.08, 0.02, 0.08, 0.12, 0.1, 0.1, and 0.14 percent.

Tabulated data on the effect of the various diets in gains in weight, content of ash in the femurs, and calcium and phosphorus content of the blood serums are given, and "demonstrate that it is possible to produce rickets in rats on a diet composed almost entirely of purified food substances if the phosphorus content is maintained at a low level. This furnishes additional evidence in favor of the view that cereals do not owe their rachitogenic properties to the presence of a specific anticalcifying agent. Also it gives a better opportunity for a study of the factors leading to the development of rickets in the rat."

Factor W and its relation to the vitamin B complex, D. V. FOSTER and C. A. ELVEHJEM. (Wis. Expt. Sta.). (*Jour. Biol. Chem.*, 128 (1939), No. 1, pp. 23-34, fig. 1).—This paper summarizes hitherto unreported properties of factor W (E. S. R., 79, p. 137), and discusses them in relating this factor to other little known members of the vitamin B complex. By partition between butanol and water at varying pH factor W has been shown to have a weak acidic nature. It is soluble in phenol and aniline but insoluble in ether and cannot be precipitated from alcohol or water by organic acid- and base-precipitating agents. It can be eluted from norite by refluxing the well-dried material with dry butanol, a 1:1 mixture of benzene and absolute ethyl alcohol, and an aqueous pyridine-methanol mixture (2:1:1). Tabulated data are given on the factor W potency of various concentrates prepared from the fuller's earth filtrate of liver extract.

The properties of factor W are discussed with reference to the work of other laboratories, with the conclusion that factor W is distinct from vitamin B₆, the chick antidermatitis factor, and nicotinic acid. The relation which factor W bears to factor 2 of Lepkovsky et al. (E. S. R., 76, p. 839) or to vitamin H of Booher (E. S. R., 79, p. 716) is not clear. There is some evidence that the factor is similar to or identical with the filtrate factor of Edgar and Macrae. Data are also reported showing that the response of rats to nicotinic acid and its amide is dependent on the composition of the ration. It is pointed out that although the fact that addition of one, two, or three members of the vitamin B complex may enhance the deficiency symptoms of other members is not new knowledge, it demands more attention in the future than it has received in the past.

The anti-acrodynic properties of certain foods, H. A. SCHNEIDER, J. K. ASCHAM, B. R. PLATZ, and H. STEENBOCK. (Wis. Expt. Sta.). (*Jour. Nutr.*, 18 (1939), No. 1, pp. 99-104).—The term anti-acrodynic activity is used in this report to signify the activity measured by the cure of the symptoms of acrodynia in rats described as erythemic, swollen, and denuded paws and fissured, swollen, and denuded lips. These symptoms were produced in from 4 to 5 weeks in rats on the diet described by Quackenbush, Platz, and Steenbock (El. S. R., 81, p. 600). The supplements tested were assumed to be curative if at the end of 3 weeks the lips, eyes, and ears were normal in appearance and paws and tails free from all symptoms except slight scaliness. It is noted that these symptoms are only temporarily relieved by crystalline vitamin B₆, and consequently that the measure of anti-acrodynic properties is not a measure of vitamin B₆ alone. Data are reported in terms of minimum curative level and maximum failing level in milligrams per day of 52 food materials. "Fruits and vegetables were found to be poor sources, fish and meat fair, seeds, legumes, and cereals relatively rich, and certain vegetable fats extremely potent sources of anti-acrodynic activity."

Ascorbic acid, a precursor of vitamin C, I, II, [trans. title], H. LUND, E. TRIER, ET AL. (*Klin. Wchnschr.*, 18 (1939), No. 3, pp. 79, 80, 80-82, fig. 1).—The Lund and Lieck methylene blue titration method (El. S. R., 79, p. 151) for quantitative determination of ascorbic acid in blood serum is based on the assumption that a given amount of ascorbic acid would have the same reducing value whether in water solution or in the serum as prepared for titration. Actual titrations on samples prepared by adding ascorbic acid to the deproteinated serum (1 mg. per 100 cc.) gave values far short of those obtained on water solutions of similar concentration. The titers were variable but amounted to only 3-61 percent of the theoretical. When the ascorbic acid was added to the serum before deproteinating, the titers amounted to more than 75 percent of the theoretical. These results are interpreted to mean that synthetic ascorbic acid is not identical with that in the blood stream, and further, that the synthetic product is only a precursor of vitamin C into which it is transformed through some particular function of the natural blood serum. The transformation is not effected by the deproteinated serum.

In part 2 a new microtitration method, involving methylene blue reduction and requiring only 0.1 cc. of serum, is described in detail as to reagents and technic. Whereas trichloroacetic acid is used as the defecating reagent in the method of Lund and Lieck, the present method employs lead acetate, which removes certain interfering substances. Either of the two methods may be used to determine the reducing substances occurring spontaneously in blood, but only the micromethod is satisfactory for determining synthetic ascorbic acid, which is considered as a precursor to vitamin C in the blood stream.

The oxidation of ascorbic acid as influenced by intestinal bacteria, W. B. ESSELEN, JR., and J. R. FULLER. (Mass. Expt. Sta.). (*Jour. Bact.*, 37 (1939), No. 5, pp. 501-521).—In this in vitro study of the action of animal intestinal bacteria on ascorbic acid and factors influencing its action, it was found that certain bacteria, particularly members of the coliform group, inhibited the oxidation of ascorbic acid in culture media, and the more actively growing cultures in which the largest numbers of bacteria were present had the strongest inhibitory action. When ascorbic acid was present in relatively high concentration, the inhibitory action of bacteria was not observed, presumably because the acidity of the medium was lowered below the point where effective bacterial growth could take place. Killed bacterial cultures or cell-free filtrates from living cultures showed no inhibitory action. Two strains only of

Escherichia coli were able to reduce dehydroascorbic acid to ascorbic acid. "It is suggested that growing bacteria inhibit the oxidation of ascorbic acid by certain combinations of three factors, namely, (1) the formation of un-ionized copper complexes whereby the catalytic action of the copper is destroyed, (2) the production of carbon dioxide with the subsequent saturation of the medium with it, and (3) the lowering of the oxygen tension of the medium. The most effective inhibitory action was obtained by a combination of all three of these factors together."

On the stability of ascorbic acid in solutions, J. LEIBOWITZ and K. GUGGENHEIM (*Ztschr. Vitaminforsch.*, 8 (1938-39), No. 1, pp. 1-7; *Ger., Fr. abs.*, pp. 6, 7).—The rate of disappearance of ascorbic acid in water, urine, and bouillon was studied with particular reference to the results obtained under different conditions and in the presence of various substances. Results on the loss of ascorbic acid in aqueous solutions were by no means directly applicable to bouillon or urine. Thus, traces of KCN (0.001 M) exerted a protective action upon ascorbic acid in aqueous solutions, but in urine or bouillon this effect was either absent or very slight. Even in aqueous solutions the preservative action of KCN was limited to the weakly acid range. In all three media the protective action of the KCN was altered by the presence of acids such as CO_2HCOOH , H_2SO_4 , HCl , and CH_3COOH in 0.1 N concentration. The degree of alteration was variable and apparently not entirely referable to pH changes. Moreover, in the presence of KCN the acid exerted a different effect than it did in the test solution alone. Not all acids exerted a protective action upon the ascorbic acid, and the influence varied with the acid used. KONS and KI acted as preservatives in aqueous solution but, like KCN, were without effect in urine.

On the detoxicating effect of ascorbic acid, J. LEIBOWITZ and K. GUGGENHEIM (*Ztschr. Vitaminforsch.*, 8 (1938-39), No. 1, pp. 8-24; *Ger., Fr. abs.*, pp. 23, 24).—Although KCN in minute amounts, and in a slightly acid medium, inhibits the oxidative loss of ascorbic acid in air, as noted above, the protective action becomes progressively weaker in higher concentrations until above a certain point KCN actually accelerates the loss of vitamin C. This effect results from the formation of a definite compound of KCN and ascorbic acid, the latter constituent being more easily oxidized in this combined state than in its free state. Proof of the chemical combination is afforded by cryoscopic methods (only in an alkaline medium). Reductometric titration indicates that the ascorbic acid in combined form is readily oxidized. KCN that has stood in contact with ascorbic acid for several days is no longer toxic to bacteria or mammals, and this further supports the *in vitro* evidence that an ascorbic acid KCN compound is formed. The late appearance of the detoxifying effect suggests that it is associated, not with the formation of the compound, but with its subsequent oxidation. It is impossible, however, to protect animals against KCN poisoning by the injection of ascorbic acid. After short contact, ascorbic acid also combines with phenol. The latter is thereby detoxified so that it no longer initiates convulsions in rats. Previous injection with ascorbic acid does not protect the rats. The bactericidal property of phenol, which is referable to its protein coagulating ability, is not attenuated by ascorbic acid.

The vitamin C exchange between mother and fetus [trans. title], J. MULLER (*Klin. Wchnschr.*, 18 (1939), No. 9, pp. 299-301).—From a review of the literature on this subject, the author presents the following summary:

Vitamin C is not stored in the placenta and there is little possibility of the fetus having the higher ascorbic acid content. Comparative determinations of

the vitamin C content of the liver of the mother, of the placenta, and of the liver of the fetus show that, apart from some variable differences, the vitamin C picture in the fetus is the same as in the mother. The findings contradict the assumption that there is synthesis in the fetus. All the vitamin C that the fetus uses is brought to it through the umbilical vein by way of the placenta. About 40 references to the literature are appended.

Potatoes as carriers of vitamin C, M. E. LYONS and C. R. FELLERS. (Mass. Expt. Sta.). (*Amer. Potato Jour.*, 16 (1939), No. 7, pp. 169-179).—From this study it may be concluded that variations in potatoes of the same variety grown in different sections of the country may be no greater than individual variations in the same sample; variations among varieties may be no greater than those among different samples of the same variety, although certain varieties averaged somewhat higher than others; the content of ascorbic acid remains rather constant from the first digging until the potatoes are fully matured, but after digging losses amounting to as much as 50 percent may occur on winter storage for 5 mo.; small variations may occur in the same potato of both large and small size; all methods of cooking result in losses which amount to about 40 percent with either baking or boiling; boiled potatoes held at 40° F. for 24 hr. retain approximately 80 percent of their ascorbic acid content and on reheating retain somewhat more of the vitamin if fried than if creamed; boiling in salted water preserves the vitamin to a somewhat greater extent than boiling in unsalted water; and an ordinary serving of potato (150 gm. or 5¼ oz.) may furnish about one-third of an estimated daily ascorbic acid requirement of 50 mg.

Vitamin C content of sauerkraut, C. S. PEDERSON, G. L. MACK, and W. L. ATHAWES. (N. Y. State Expt. Sta.). (*Food Res.*, 4 (1939), No. 1, pp. 31-45, figs. 3).—An extensive series of chemical determinations of the vitamin C content of sauerkraut in relation to the original cabbage and changes taking place during fermentation, storage, canning, and repacking in barrels is reported.

Raw kraut sampled during and immediately after fermentation in commercial-size vats was found to contain approximately the same quantity of vitamin C as the original cabbage. During storage in the vats after fermentation the content decreased slowly. In samples fermented in smaller containers the loss was more rapid. Canned kraut showed some loss of vitamin C, which was traced primarily to the mixing and preheating before the kraut was put into cans. Little decrease was noted during the further processing and storage. Kraut repacked in barrels lost vitamin C, the loss being more rapid in barrels stored at a low temperature (1° C.) than at a higher temperature (20°) where fermentation continued. The loss of vitamin C in kraut is thought to be associated with the loss of carbon dioxide after fermentation is complete.

Ascorbic acid (vitamin C) in tomatoes and tomato products, W. A. MACLINN and C. R. FELLERS (*Massachusetts Sta. Bul.* 354 (1938), pp. 39, fig. 1).—This bulletin includes an extensive review and list of the literature on the subject, with a summary in tabular form of data from all available published reports on the vitamin C content of raw, canned, fermented, and dried tomatoes, tomato conserve, and canned tomato juice; a discussion of biological and chemical methods for the determination of ascorbic acid, with an outline of the technics employed by the authors in the standardization of the dye and preparation and titration of tomatoes and tomato juice, and a comparison of the dye, modified iodine, and bio-assay methods as applied to tomato juice; and the report of the investigation proper, which covered three successive crops of tomatoes, and tests on the effects of various factors on the ascorbic acid content.

The general results of the first year's study of 98 strains and varieties has been noted from a preliminary report (E. S. R., 78, p. 728). In the second year 28 and in the third 22 of the same varieties and strains were tested, thus making possible a seasonal comparison of the same strains and varieties grown on the same soil and with the same fertilizer treatment. The same general relationship among the varieties was shown each year, but in all cases the 1937 crop gave lower values than the 1936, while the 1938 crop gave values more comparable with the 1936 crop. Although there were individual variations due to other uncontrolled factors, the comparison of the data for the 3 yr. tended to show that the ascorbic acid potency in tomatoes may be an inherited characteristic. It is considered that tomatoes should have an ascorbic acid content in excess of 150 International Units per ounce to be classed as higher than average.

No correlation was found between size of tomato and ascorbic acid content. In the one variety tested for distribution in various parts of the fruit, the concentration was highest in the locule section, but the outside flesh and skin contributed the largest percentage of the total ascorbic acid content of the whole fruit. Six varieties showed no significant increase in ascorbic acid during the ripening from a hard green to a hard ripe stage. Storing tomatoes in parchment wrappers did not affect the ascorbic acid content, and there were no losses when tomatoes were stored 240 hr. at room temperature.

During canning the loss of ascorbic acid was insignificant in the heating and pulping processes but considerable during concentration as is commonly practiced in the home canning of tomato juice. It is noted that in commercial canning homogenization is used in preference to concentration to prevent the separation of finely divided particles. Tomato juice stored in plain glass containers showed a small continuous loss of ascorbic acid when kept either in the light or dark. In amber glass containers the destruction was checked up to at least 80 days. In tin no losses occurred during a 30-day period. Commercial brands of tomato juice contained from 40 to 100 I. U. of ascorbic acid per ounce. Samples within a single brand varied from 28 to 85 units per ounce. Storage of opened tins of tomato juice at 21° C. was more destructive of ascorbic acid than storage at 5°, the average household refrigerator temperature. Under the latter conditions a 10- to 15-percent loss resulted after 20 hr. or more.

Vitamin C in Virginia apples, M. J. SATOHI'S. (Va. Expt. Sta.). (*Va. Fruit*, 27 (1939), No. 7, pp. 13, 14).—Varieties of Virginia-grown apples as analyzed for 1 yr., both fresh and stored, ranked in decreasing vitamin C content in the order—Black Twig, Winter Banana, Ben Davis, Winesap, York Imperial, North-western Greening, Stayman Winesap, Red Rome, Arkansas Black, Rome Beauty, Virginia Beauty, Jonathan, Delicious, Senator Oliver, Grimes Golden, and Lowry. It is estimated that from 2 to 3 apples a day of the first-named variety would supply the vitamin C requirement for an adult man, whereas it would take from 6 to 8 apples of the varieties at the end of the list. Storage at 38° F. for 6 mo. resulted in an average decrease in vitamin C content of 45 percent. In general apple peel was from 4 to 5 times as rich in vitamin C as the flesh.

Subacute avitaminosis C [trans. title], G. MOURIQUAND, V. EDEL, and M. DAUVEGNE (*Compt. Rend. Soc. Biol. [Paris]*, 130 (1939), No. 7, pp. 667-669).—A stage in vitamin C deficiency midway between acute and chronic scurvy has been produced in guinea pigs by the administration of 0.25 mg. of ascorbic acid daily as a supplement to a scurvy-producing ration on which with 0.5 mg. of ascorbic acid scurvy of the chronic type is produced. In the subacute con-

dition the animal retains its appetite and continues to grow, although hemorrhagic symptoms of vitamin C deficiency appear about as early as in acute or chronic scurvy. If vitamin C treatment is given at about the thirty-fifth or fortieth day the symptoms do not yield as rapidly as in acute scurvy and may even progress to the death of the animal at about the fiftieth day. Examination of the blood at the fortieth day shows an anemia which is accentuated as the end approaches. X-ray examination reveals extensive decalcification of the epiphyses without the habitual periostosis of chronic scurvy. On autopsy the customary scorbutic lesions are found, with a pronounced deficiency of vitamin C in the adrenals. It is suggested that this type of scurvy resembles human scurvy more closely than either the chronic or acute scurvy of the guinea pig.

A low phosphorus diet and the response of rats to vitamin D₂. H. SCHNEIDER and H. STEENBOCK. (Wis. Expt. Sta.). (*Jour. Biol. Chem.*, 128 (1939), No. 1, pp. 159-171, fig. 1).—A synthetic low phosphorus vitamin D-free diet adequate in other nutritional requirements of the rat has been devised and used in place of the customary cereal rachitogenic diets for the study of rickets in rats. The diet consists of cerelese (glucose) 49 parts, egg white 18, cooked starch 20, a vitamin B concentrate vitab 4, phosphorus-free salts 4, and cottonseed oil 5 parts. Unsupplemented the diet contained 0.04 percent phosphorus and supplemented with 1.8 parts of $\text{NaH}_2\text{PO}_4 \cdot \text{H}_2\text{O}$ 0.41 percent of phosphorus, the same content as when supplemented with 4 percent of Wesson salts. The basal diet alone is designated as R-14, supplemented with the phosphate as NR-14, and supplemented with Wesson salts as WR-14.

The unsupplemented diet R-14 produced rickets in from 12 to 14 days, cessation of growth in from 4 to 5 weeks, and death with severe skeletal deformities in 6 weeks. When the diet was supplemented with vitamin D the healing of the metaphyses was identical with that observed when like amounts were fed in cereal diets, but growth was unsatisfactory or ceased entirely. Calcium and phosphorus balances and tissue analyses showed that vitamin D induced the utilization of phosphorus by the bones at the expense of depriving the soft tissues of their supply, thus inhibiting growth. When supplemented with sufficient phosphorus (diets NR-14 and WR-14) and vitamin D, the diets proved satisfactory for the nutrition of three successive generations.

Effect of amino acids on anemia caused by deaminized casein. R. E. GUERRANT and A. G. HOGAN. (Mo. Expt. Sta.). (*Jour. Biol. Chem.*, 128 (1939), No. 1, pp. 563-572, figs. 2).—In further attempts to identify the agent which corrects the anemia caused by deaminized casein (E. S. R., 78, p. 280), hydrolyzed casein was fractionated and the soluble amino acids (which alone proved effective) were subjected to further fractionation with solid barium hydroxide and alcohol. This left the activity in the amino acids not precipitated as barium salts. Copper salt fractionation of these amino acids gave three fractions, the most active of which was the one insoluble in methyl alcohol but soluble in water. The amino acids separated from the copper salts were ineffective, as were also the essential amino acids not expected to be in the fraction. Various explanations for the negative results are suggested, with the statement that "since it now seems certain that this type of anemia can be prevented by certain of the amino acids, a solution of the immediate problem can be anticipated with some confidence."

Enlargement of the spleen of anemic rats similar to that reported by Hamre and Miller (E. S. R., 74, p. 286) is described.

TEXTILES AND CLOTHING

A study of certain factors related to consumers' choices in the purchase of "silk" street dresses and silk yard goods, E. L. PHELPS, F. E. PETZEL, A. S. LORING, and E. A. NIELSON. (Minn. Expt. Sta.). (*Jour. Home Econ.*, 31 (1939), No. 6, pp. 393-398).—Data collected in Minneapolis during the summer and fall of 1931 and winter of 1932 through personal interviews and observations of purchases are reported on the influence of various factors, including outside employment, age, and income, on consumer choices in silk street dresses and silk yard goods. In all 294 women were interviewed, only 68 of whom were employed outside the home. In addition 303 sales in the silk department of a large department store were observed.

Employment outside the home apparently had no influence on the average number of street dresses in active use or on the use of different kinds of silk fabrics. The women's wardrobes (street dresses) were composed chiefly of dresses thought to be of silk, over half of which were crepe, plain in color, and bought ready to wear. It is pointed out that the problems involved in purchasing street dresses and yard goods for dresses are important. Since ready-to-wear dresses of one type of fabric were the principal choice, "It is evident that reliable standards and dependable labeling are needed as guides to the quality of both workmanship and material."

Consumer demand in Missouri for selected articles of clothing, J. V. COLES (*Missouri Sta. Res. Bul.* 300 (1939), pp. 58).—This consumer preference study was limited to women's house dresses, afternoon dresses, slips, and hose. Information was secured by the questionnaire method from 1,917 women, the majority of whom were classed as small-town buyers, as they lived on farms and in villages or small towns. As some of the women filled out questionnaires for more than one commodity, 2,990 questionnaires were analyzed. For each commodity the information thus secured is presented under the headings—character of present purchases, demand for specific qualities, effect of income on practices and preferences, difficulties encountered in buying, and difficulties with wearing qualities. The types of store patronized by small-town and city buyers, price ranges of the commodities, and reasons for and against purchasing dresses and slips instead of making them in the home are included.

Among the difficulties most frequently mentioned were inability to secure correct sizes because the labeled sizes varied from actual sizes, difficulties in getting satisfactory leg lengths in hose, and difficulties in getting preshrunk and colorfast fabrics and pure-dye silks. Dissatisfaction was expressed with the construction of ready-made house and afternoon dresses and slips, particularly from the standpoint of finish and depth of seams. Inability to secure the desired articles because dealers did not carry them was naturally encountered more often by small-town than by city buyers.

Consumer demand in Missouri for selected articles of household textiles, J. V. COLES (*Missouri Sta. Res. Bul.* 301 (1939), pp. 46).—This study is similar in attack, sources of information, and analysis of data to the one noted above. The household textiles concerning which information was obtained by the questionnaire method from small-town (1,675 questionnaires) and city (1,073 questionnaires) buyers included blankets, window curtains (excluding draperies), towels, and sheets. The principal difficulties encountered in the purchase of sheets was the inability to get the size desired, particularly in length; of blankets difficulty in securing sizes and fibers desired and trouble with shrinkage and fading; of window curtains difficulty in securing really preshrunk and colorfast fabrics and lack of proper labeling on materials and difficulty

in getting desired sizes in ready-made curtains. Fewer difficulties were reported for towels, although there was some difficulty in getting the desired quality in ready-made towels. In this study also the inability to secure the articles desired because the dealers patronized do not carry them was a common complaint of the small-town buyers.

Résumé of an eight-year series of consumer studies on silk and rayon, P. B. MACK, F. G. WINNING, S. STARK, and E. R. GRAY. (Coop. Univ. Ill. et al.). (*Pa. State Col. Bul.*, 33 (1939), No. 42, pp. [2]+220, figs. 8).—The results of a long-time investigation dealing with the extent and reliability of consumer information on silk and rayon fabrics and ready-made garments is presented in a series of separate reports as follows: Silk Dress Study I—Style, Workmanship, Size, and Fit of Garments in Relation to Price, by F. G. Winning and P. B. Mack (pp. 3-14); Silk Dress Study II—Characteristics of Fabrics and of Garments in Relation to Each Other and to Price, by P. B. Mack and F. G. Winning (pp. 15-35); Silk Dress Study III—Durability of Fabrics, by G. E. Cook and P. B. Mack (pp. 36-53); Testing Silk Fabrics for College Girls' Uniforms, by P. E. Keeney, G. P. Fulton, P. B. Mack, and S. Stark (pp. 54-61); A Study of Silk Underslips, by M. Laramy and P. B. Mack (pp. 62-64); Silk Yardage on the Market in 1934-1935, by M. D. Hale and P. B. Mack (pp. 65-70); What Consumers of Silk Want, by E. R. Gray and P. B. Mack (pp. 71-79); Why Silk Dresses Are Discarded, by M. D. Hale and P. B. Mack (pp. 80-85); Consumers' Judgment of Silk Fabrics, by G. E. Cook, M. Y. Moore, and P. B. Mack (pp. 86-94); A Study of Woven Rayon Fabrics on the Wholesale Market, by M. D. Hale, E. C. Hoffman, and P. B. Mack (pp. 95-105); A Study of Woven Rayon Fabrics on the Retail Market, by M. C. Green and P. B. Mack (pp. 109-133); Why Inexpensive Rayon Dresses Are Discarded, by M. E. Gregory and P. B. Mack (pp. 139-167); A Study of the Fastness of Dyes on Miscellaneous Dress Fabrics, by C. R. Phillips and P. B. Mack (pp. 168-213); and Trends in Consumer Information Concerning Silk and Rayon, by P. B. Mack (pp. 214-220).

HOME MANAGEMENT AND EQUIPMENT

Bibliography on consumer education, G. C. MANN (*New York and London: Harper & Bros.*, 1939, pp. IX+286).—This annotated bibliography includes 1,981 titles of books, periodicals, etc., published up to November 15, 1938, grouped under the headings (1) consumer economics, including history and scope of the consumer movement, the place of the consumer in our economic system, family budgets and standards of living, standards, labels, and consumer protection, prices, advertising and other methods of stimulating buying, cooperatives, Government and the consumer, and money and credit; (2) information on purchasing grouped under different commodities; (3) teaching consumer education, including textbooks, teaching aids, curricula, and projects; (4) references, including bibliographies, magazines, and publications; and (5) general, including commercial publications. Author and subject indexes and lists of publishers, periodicals, and commercial concerns are included in appendixes.

Important consumer problems of the rural family of the South (*Assoc. South. Agr. Workers Proc.*, 40 (1939), pp. 126-129).—Abstracts are given of contributions to this panel discussion: Finance and Credit, by D. Dickins (*Miss. Expt. Sta.*); Clothing, by M. A. Grimes (*Tex. Sta.*); Education, by E. E. Proctor; and Household Equipment Needs in Farm Homes of the South, by M. A. Mason.

[**Meeting farm family expenses**], D. DICKINS (*Miss. Farm Rec. [Mississippi Sta.]*, 2 (1939), No. 7, pp. 1, 8).—In this comparison of the incomes and expendi-

tures of 23 Mississippi farm families who lived within their current income during 1938-39 with those of 23 comparable families whose expenses exceeded their income during the same period, the most important difference between the two groups was in the value of the food produced for home consumption, averaging \$308 and only \$215, respectively. This, together with the fact that the latter group spent only \$5 a year more than the former on purchased foods, shows that insufficient production of food on the farm was not made up by cash purchases and explains in part the greater sickness during the report year of the low-producing group. It is thought that an abundance of home-produced food is about the only guarantee the typical farm family of Mississippi has of getting a good diet and in turn better health.

Greater cash income for rural girls a community problem, D. DICKINS (*Miss. Farm Recs. [Mississippi Sta.]*, 2 (1939), No. 3, p. 4).—Attention is called to the very limited gainful employment for out-of-school girls and young women on the farms in the State, with data in illustration from a random sample of white women in two of the poorer agricultural counties. A few suggestions are given for possible remunerative work, and community responsibility for initiative in the development of opportunities is urged in order that this group may have the experience of handling money of their own making.

Wood finishes, B. M. KUSCHKE (*[Rhode Island Sta.] Misc. Pub.* 3 (1939), pp. 7, figs. 2).—Certain facts concerning types of floor finishes and methods of applying them, acquired in the course of an extensive investigation still in progress, are presented for the guidance of homemakers in the choice, application, and care of finishes. Special emphasis is given to penetrating seal finishes and water emulsion waxes, and simple tests for quality in the latter are described. The use of color in floor finishes, the preparation of surfaces to be painted, paint cleaning with a dilute glue solution, and treatment of concrete floors to prevent the tracking of grit are among the topics discussed.

Study of the kinds and maintenances of floor finishes best suited for household use (*Rhode Island Sta. Rpt.* [1938], pp. 50, 51).—Progress is noted on a comparison of different finishes for soft pine flooring.

MISCELLANEOUS

Forty-ninth Annual Report of the Storrs Agricultural Experiment Station, Storrs, Connecticut, for the year ending June 30, 1937, W. L. SLATE ET AL. (*[Connecticut] Storrs Sta. Rpt.* 1937, pp. [471], pls. 28, figs. 58).—This includes reprints of Bulletins 221-229, all of which have been previously noted.

[Reports of progress, Indiana Station experiment fields and farms], A. T. WIANCKO ET AL. (*Indiana Sta. Cirs.* 242 (1939), pp. 20, fig. 1; 243, pp. 8; 244, pp. 8; 245, pp. 4; 246, pp. 4; 247, pp. 7; 248, pp. 8).—These circulars report data noted elsewhere in this issue for the following: Nos. 242, Soils and Crops Experiment Farm, 1915-38; 243, Bedford Experiment Field (Moses Fell Annex), 1916-38; 244, Jennings County Experiment Field, 1921-38; 245, Herbert Davis Forestry Farm Soils and Crops Experiments, 1923-38; 246, Huntington Experiment Field, 1919-38; 247, Sand Experiment Field, 1924-38; and 248, Pinney-Purdue Experiment Fields, 1920-38.

Forty-ninth Annual Report [of New Mexico Station, 1938], F. GARCIA (*New Mexico Sta. Rpt.* 1938, pp. [1]+88, figs. 17).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

Fifty-first Annual Report [of Rhode Island Station, 1938], B. E. GILBERT (*Rhode Island Sta. Rpt.* [1938], pp. [2]+64+[1], fig. 1).—The experimental

work not previously referred to is for the most part noted elsewhere in this issue. Temperature and precipitation records are also summarized.

Farm Research, [July 1, 1939] (*Farm Res. [New York State Sta.]*, 5 (1939), No. 3, pp. 12, figs. 12).—In addition to several articles noted elsewhere in this issue and brief notes, this number includes State Jersey Cattle Club Field Day and Sale a Success, by A. C. Dahlberg (p. 7); Mexican Bean Beetle Here To Stay, by H. C. Hockett (p. 8); and The Use of the Financial Stimulus in High Grade Milk Production, by R. S. Breed (p. 10).

Bimonthly Bulletin, [July 1939] (*North Dakota Sta. Bimo. Bul.*, 1 (1939), No. 6, pp. 27, figs. 3).—In addition to articles noted elsewhere in this issue and brief abstracts of current contributions to agricultural science, this number contains Wheat Crop Improvement and Wheat Quality, by R. H. Harris (pp. 4-6); The Bluegrasses of North Dakota, by O. A. Stevens (pp. 6, 7); and Official Tractor Tests, by H. F. McColly (pp. 8, 9).

NOTES

Arkansas University and Station.—Dr. John C. Futrall, associated with the institution since 1894 and president since 1914, was killed in an automobile accident September 12 at the age of 66 years. A native of Tennessee, President Futrall was granted the B. A. and M. A. degrees from the University of Virginia, took additional graduate work at the University of Chicago, Johns Hopkins University, and the Universities of Bonn and Halle, and received honorary LL. D. degrees from Tulane University and the University of New Mexico. He was president of the National Association of State Universities in 1925-26 and the Association of Land-Grant Colleges and Universities in 1932-33.

The resignations are noted of J. G. McNeely, instructor in rural economics and sociology, R. M. Theis, instructor in agricultural chemistry, and R. S. Woodward, technical assistant in the Fruit and Truck Substation. Hosea Fincher has been appointed manager of the university creamery, vice W. P. Cotton resigned.

California University and Station.—At the recent celebration of the fiftieth anniversary of the founding of the University of Sofiya, the degree of doctor of agriculture was awarded Dean and Director C. B. Hutchison in recognition of assistance given the university from 1924 to 1927 as a member of the European Mission of the International Education Board of the Rockefeller Foundation.

Charles F. Shaw, professor of soil technology since 1913, died September 12, aged 58 years. A native of New York and a graduate of Cornell University in 1906, he was associated with soils work there from 1905 to 1906, with the U. S. D. A. Bureau of Soils from 1906 to 1907, and the Pennsylvania College and Station from 1907 to 1913. He had also served as a visiting professor at the University of Nanking in 1930 and in an advisory capacity with the Bureau of Soils from 1909 to 1913 and the Mexican Irrigation Commission from 1926 to 1928. He was widely recognized as an authority in soil morphology and taxonomy, serving as president of the Soil Science Society in 1927 and since 1936 as president of the North American subcommittee of the International Society of Soil Science.

Arthur H. Folger, superintendent of official testing in the department of animal husbandry at Davis, has resigned to become a regional director in the U. S. D. A. Farm Security Administration.

Connecticut University and Storrs Station.—The university has accepted from the Eastern States Farmers' Exchange a grant of \$1,800 per year for research in nutritional diseases under the direction of the station. A similar grant from the New England Epidemic Tremor Research Association, Inc., of at least \$2,500 will also be under the direction of the station animal diseases department for a study of avian encephalomyelitis, commonly known as epidemic tremor.

The university department of economics has been reorganized by division into departments of economics and agricultural economics, headed, respectively, by Albert El. Waugh and Donald O. Hammerberg,

Dr. Dorothea Rudnick, research assistant in genetics, has resigned to accept a position in Wellesley College and has been succeeded by Elizabeth Baumann. Carl F. Clancy, research assistant in animal diseases, has resigned to continue graduate work in Yale University and has been succeeded by Jacob Levine.

Florida University and Station.—*Science* notes that the U. S. Sugar Corporation of Clewiston, Fla., has made a gift of \$1,000 to establish the Napoleon B. Bernard fellowship for graduate work on the soil, climate, and agriculture of the Everglades.

Iowa College and Station.—Lee W. Forman, superintendent of experiments and research assistant professor, died September 9, aged 58 years. A native of Iowa, he received the B. S. degree there in 1900 and the M. S. A. degree in 1913. He had been connected continuously since 1909 with the soils work of the institution, giving special attention to soil fertility and in recent years to pasture improvement.

Kansas College and Station.—Dr. D. B. Creager has resigned as assistant professor of botany and plant pathology. Dr. C. C. Morrill, associate professor of pathology in the division of veterinary medicine, resigned August 31, and was succeeded by Dr. R. P. Wagers. Merton L. Otto has been appointed instructor in agricultural economics.

Louisiana University.—Lawrence V. George has been appointed station editor, effective September 1.

Maine Station.—Donald H. Perrin has been appointed field assistant in entomology to have charge of the winter testing in Florida of Maine-grown seed stocks of potatoes and of the new Foundation potato seed-stock program, which is handled in Maine during the summer. Joan H. Stacy has been appointed assistant in biology vice Carol H. Griffin, resigned.

Massachusetts Station.—Oreana A. Merriam, research assistant in home economics nutrition, resigned September 1 to accept a teaching position in the Plattsburg, N. Y., Teachers College and has been succeeded by Anne W. Wertz.

Mississippi College and Station.—William R. Perkins, vice director emeritus since 1937, died August 21 at the age of 72 years. Graduating from the college in 1891, he remained there as assistant chemist for 2 years and as professor of agronomy and agronomist for 17 years. From 1910 to 1912 he was associated with the agronomic work of Clemson College and from 1915 to 1928 with that in Louisiana. Returning to Mississippi as assistant director of the South Mississippi Substation, he became director of the station in 1930 and in 1932 assistant director. At the time of his death he was engaged in a compilation of a history of the station. In the words of a recent tribute in *Science*, "he was widely known in the Southern States for his work as an agricultural chemist, agronomist, and administrator in extension and experiment stations. He early recognized the economic futility of a one-crop system, cotton, and the distress to which it would finally lead southern agriculture. He saw the boundless possibilities in the growing of forage crops and the production of livestock under the most favorable climatic conditions in this country. In and out of season, he counseled conservation of the soil and diversification of agriculture. . . . Southern agriculture has lost a zealous advocate, an able administrator, a careful student, and a just man."

Missouri University and Station.—By special provision of the legislature, instruction and investigation work in floriculture has been established. James E. Smith, Jr., has been appointed in charge of this project.

Montana College and Station.—Dr. P. L. Nagsvold has resigned as professor of agricultural economics and agricultural economist effective Septem-

ber 1 to accept a position as Chief of the Planning Section, U. S. D. A. Farm Security Administration, with headquarters at Denver, Colo. M. A. Bell, superintendent of the Northern Montana Substation, has resigned to become superintendent of the Woodward, Okla., Field Station and supervisor of experiment stations operated by the Division of Dry Land Agriculture of the U. S. D. A. Bureau of Plant Industry for the southern Great Plains.

Dr. A. R. Patton, research assistant in poultry husbandry in the Colorado Station, has been appointed head of the department of chemistry and meteorology in the station vice Edmund Burke, who became consulting chemist September 1. Other appointments effective September 1 included Samuel C. Litzberger as instructor and assistant in agronomy and John N. Cummings as assistant in animal husbandry. On October 1 Dr. Waldo E. Carlson succeeded Dr. Frank T. Donaldson, resigned, as assistant professor of chemistry and meteorology.

New Mexico College and Station.—G. R. Hamiel, formerly associate professor of chemistry and associate chemist, is devoting full time to teaching chemistry. The following appointments have been made as instructors and assistants in the station: J. L. Flowers, agronomy; Dr. T. D. Bell, animal husbandry; Dr. E. C. Smith, chemistry; and G. W. Schneider, horticulture.

Cornell University.—The first wing of a \$300,000 laboratory building for nutrition research is under construction.

North Dakota College and Station.—Effective July 1, the institutions of higher learning, the station, the extension service, and the State system of vocational education were placed under the control of a State Board of Higher Education. This board was created by an initiated constitutional amendment which removed the control of the foregoing institutions from the State Board of Administration. The new board consists of seven appointees by the Governor with the approval of the State senate, selections being made from a list of three nominees for each vacancy submitted by the unanimous choice of a nominating committee consisting of the then sitting chief justice of the supreme court, the State superintendent of public instruction, and the president of the North Dakota Educational Association. The original members of the board are appointed for terms ranging from 1 to 7 years and thereafter for 7 years, and removal is possible only by impeachment by the house of representatives followed by conviction by the State senate.

Ohio Station.—Dr. Charles F. Rogers, instructor and assistant in agricultural biochemistry in the Minnesota University and Station, has been appointed associate in biochemistry.

Rhode Island College and Station.—President R. G. Bressler has been appointed acting director of the station and extension service.

Clemson College.—President E. W. Sikes has tendered his resignation, with a view to retirement, but has consented to remain in office until his successor has been selected.

South Dakota College and Station.—Joseph G. Hutton, professor of soils and associate agronomist, died September 22 at the age of 65 years. A native of Indiana, he completed his undergraduate work at the University of Chicago in 1908 and received his M. S. degree from the University of Illinois in 1910. He had been associated with the department of agronomy since 1911, being virtually a pioneer in the field of fertility and conservation of South Dakota soils. He was also recognized as a poet, philosopher, and scholar, contributing to various anthologies of verse and conducting a program which he called *Farm Rhymes* over the college radio station.

Recent additions to the station include Lida M. Burrill as research assistant in home economics and John A. Rohlf as assistant editor.

Virginia Station.—A. B. Stephenson has been appointed assistant poultry husbandman.

Washington Station.—F. B. Wolberg has been appointed dairy husbandman at the Western Washington Substation.

Wisconsin University and Station.—Frederick L. Musbach, professor of soils and since 1912 in charge of Marshfield Substation, died on September 14 following an automobile accident. Born in Wisconsin in 1877 and graduating from the university in 1909, his early work was on the Soil Survey of northern Wisconsin. He did much to develop experimental work on soil management both at Marshfield and through the Spooner and Ashland Substations, and had large influence on the improvement of farm practice in central and northern Wisconsin.

Frances L. Zuill, director of home economics at the University of Iowa, has succeeded Abby L. Marlatt, retired, as director of home economics.

Necrology.—Hon. Fred S. Purnell, a Member of Congress from Indiana from 1917 to 1933 and sponsor in the House of Representatives of the legislation culminating in the Purnell Act of 1925 for the increased support of the State agricultural experiment stations, died in Washington, D. C., on October 21 at the age of 57 years. Since 1938 he had been associated with the legal staff of the General Accounting Office.

Thomas D. Rice, a senior soil scientist in the U. S. Department of Agriculture, died August 23 at the age of 61 years. A native of Florida and a graduate of the University of North Carolina in 1900, he became associated with the Bureau of Soils in 1901 and had become closely identified with the Soil Survey, especially in its examination of prairie soils.

New Journals and Changes.—*Ceres* is a bimonthly published by the Ceres Club of the College of Agriculture and Veterinary Science at Viçosa, Minas Geraes, Brazil. It is intended to include both original articles and practical information pertaining to agriculture, veterinary medicine, and rural industries. The initial number contains among others Progress in Cotton Improvement at the College, by J. B. Griffing; Some Factors Which Influence the Milk Production of Mixed Simmental Cows Under a System of "Returns" (Breeding Back to Native Stock), by G. G. Carneiro; Green Manure, by A. Dorofeeff; Biological Control of Insects, by R. W. El. Tucker; Manufacture of Wine From Oranges, by M. Pavageau; Some Amaryllis of the Region as Material of Great Value for the Study of Cytology, by E. Alencar; The Planting of Citrus Orchards, by G. Corrêa; Folding of the Leaves of Sugarcane, by O. A. Drummond; and The Value of an Adherent Gas in Combating Leaf-Eating Ants and Termites, by B. T. Snipes. News notes, abstracts (mainly credited to *Experiment Station Record*), and other material are appended.

Agrografia Lusitana is being published as a quarterly under the auspices of the National Agricultural Station of Portugal. It is intended essentially as the organ for publication of the studies carried on at the station, but foreign contributions are welcomed. The initial number contains the following articles: Bud Mutations in Portuguese Pear and Apple Varieties, by J. Vieira Natividade; On Bedysis in the African Migratory Locust, by A. J. Duarte; Some Portuguese Mycetes, by Emmanuele de Sousa da Camara and Carlos Gomes da Luz; Studies on *Puccinia anomala* Rost, by Branquinho D'Oliveira; and Inoculation Experiments with *Bacterium savastanoi* El. F. Smith, and *Bacterium savastanoi* var. *frasinii* N. A. Brown, by Maria de Lourdes D'Oliveira.

Science Progress, now in its thirty-fourth volume, has suspended publication because of the war conditions.

INDEX OF SUBJECTS

NOTE.—The abbreviations "Ala.", "Conn.[New Haven]", "Mass.", etc., after entries refer to the publications of the respective State experiment stations; "Hawaii" and "P.R." to those of the experiment stations in Hawaii and Puerto Rico; "Can." to those of the experiment stations in Canada; and "U.S.D.A." to those of this Department.

Abortion—*see also Brucella abortus.*

agglutination test for, Ind. 707.

agglutination test for, accuracy, Wis. 104.

agglutination test for, sources of error in, 841.

control, 279.

control, accomplishments and difficulties in, 709.

eradication from dairy herds, Tex. 97.

immunization studies with vaccines of graded virulence, 107.

in cattle free from Bang's disease, causes, 713.

in cattle, possible transmission from horses, 573.

in ewes, 574, Wyo. 569.

in India, significance to public health, 836.

studies, 569, Calif. 273, Ind. 707, Tex. 104.

tests, comparative results of tube and plate method, 708.

trichomonad, in cattle, Tex. 104.

Acanthocephala, variability in hock measurement, 105.

Acanthocephalan life histories, developmental stages in, 836.

Acantholyda erythrocephala, notes, 670.

Acanthopsyche funodi—

control with natural cryolite, 396.

gustatory reactions and feeding on dusted foliage, 395.

Acanthoscelides obtectus, *see* Bean weevil.

Acaulopage marantica n.sp., description, 183.

Accounting, farm, *see* Farm accounting.

Accounts, cost, in Northern Ireland, experiences with, 431.

Aceratagailia sanguinolenta juices, inhibition of virus activity by, 52.

Acetic acid, preservative effects, Mass. 591.

Acetonuria in dairy cattle induced by feeding grass silage, 98.

Acids—

amino, *see* Amino acids.

fatty, *see* Fatty acids.

Acrodynia, rat—

effect of environmental temperature, 600

effect of essential fatty acids, 600.

Actinobacillosis—

and actinomycosis in animals of India, 708, 837.

in sheep, 282.

Actinobacillus lignierii, notes, 282.

Actinomyces—

erythropilis, destruction of salicylic aldehyde in soil by, 226, 660.

neorophorus cultures, improved medium for storage, 570.

necrophorus, liver abscesses in cattle due to, 279.

Actinomycetes, thermophilic, in soils and in composts, 176.

Actinomycosis—

and actinobacillosis in animals of India, 708, 837.

Adiantum ovineatum, response to the photoperiod, 180.

Adrenal atrophy and senescence produced by vitamin deficiency, 743.

Adrenals, effect on reproduction and lactation cycles, 359.

Aecidium foeniculi, relation to *Uromyces graminis*, 53.

Aedes—

aegypti, *see* Yellow-fever mosquitoes.

dorsalis in Owens Valley, California, 681.

mosquitoes, ground beetles predatory on eggs, 820.

spp., repellents for, 550.

thibaulti, habits, 820.

Aeolus dorsalis in bluegrass sod, Ky. 821.

Aerobacter aerogenes—

effect of bile and bile salts on, 490.

gum production by, Mass. 591.

Agnesia, cerebellar, three cases, 839.

Aggridsandance, approach to, study of individual versus group needs, 192.

Agrarian reform, Mexican, 854.

Agricultural—

Adjustment Act—

effect on farm organization and operation, 430.

probable effect on supply and price of corn, Iowa 292.

probable effect on wet-milling industry, Iowa 292.

Adjustment Administration—

program, effect on regional specialization in agriculture, 430.

programs, regional, effects, Iowa 121.

adjustment and marketing, 584.

areas of Mississippi, Miss. 762.

census, world, 444.

colleges—*see also specific colleges.*

organization lists, U.S.D.A. 300.

Commodities Act, Perishable, digest of decisions of Secretary of Agriculture under, U.S.D.A. 439.

commodities, trading in futures, U.S.D.A. 438.

conditions and policies, 751.

conservation program and low-income farms, W.Va. 133.

cooperation in Canada, 854.

cooperation in Oklahoma, Okla. 290.

cooperation, yearbook of, 859.

credit, S.Dak. 291.

credit, long-term, facilities in Great Britain, 441.

credit, optimum amount for farmers, 725.

credit, policy and land values, 431.

credit, short-term, data, S.C. 122.

credit, systems, 441.

development, relation to international trade, 854.

economics—

contribution to farming, 430.

contribution to general welfare, 430.

information, presenting, graphic methods, 431.

introduction, treatise, 300.

Society, British, papers, 431.

education—

and research, relation to development of British agriculture, 431 for adolescents in Pennsylvania, 299.

in college and county, 751.

programs, 299.

engineering, *see* Engineering.

equipment, pneumatic tires for, Iowa 115.

experience, recent, in Elre, 854.

experiment stations, *see* Experiment stations.

extension, *see* Extension.

income and relief to farmers, W.Va. 132.

industry, effect of Agricultural Adjustment Act, Iowa 292.

Agricultural—Continued.

insurance, systems, 441.

investigations, special, Oreg. 157.

journals, new, 464, 607, 892.

labor—*see also* Labor.

and social standards, 853.

household, annual employment cycle, Wash. 446.

in Pacific States, social aspects, 135.

organization in France, 446.

social aspects in South, 134.

wage rates in Southwest, 446.

machinery and implement industry, report, 131.

machinery in Indiana, cost of using, Ind. 852.

planning and the agricultural economist, 290.

policies, recent Japanese, U.S.D.A. 720.

policy, fundamentals, 290.

policy, government, and land values, 431.

population in California, composition and characteristics, Calif. 728.

price control in foreign countries, U.S.D.A. 131.

prices and purchasing power, Okla. 585.

production expenditures, changes in and flexibility, Iowa 120.

Canaries, types of *Tenospasma*-like bodies in, 105.

Cancer—

- characteristics, relation to environment and plant world analogy, 47.
- formation, and sex hormones, relation, 810.
- susceptibility in mice, chromosome behavior in, 192.

Cane borer, red-necked, control, Okla. 68.

Cane, field transport on steel and rubber, 118.

Cankerworm—

- fall, control by solid-stream spraying, 818.
- injury to shelterbelt plantings, N.Dak. 818.
- studies, U.S.D.A. 680.

Canned fish, spoilage in, evaluation, 8.

Canned food, retaining flavor in, N.Y.State 759.

Cantaloup, *see* Muskmelon(s).

Canthox pluvialis—
host of *Sarcophaga alcedo*, 237.
notes, P.R. 250.

Capillaria—

- columbae*, development and transmissibility to chickens and turkeys, U.S.D.A. 848.

columbae infection of chickens, cellular elements and hemoglobin in blood, 112.

contorta in turkeys, 579.

Capitophorus fragaefolia, *see* Strawberry aphid.

Capons—

- production, S.Dak. 255.
- protein requirements, Wis. 554.

Caproic acid, production by fermentation of ethyl alcohol, 187.

Carabae, unreported acarine parasite of, in Philippines, 714.

Carbohydrate metabolism, relation to boron nutrition, 767.

Carbohydrates, translocation in sugar beets, 350.

Carbon—

- dioxide, action on soils, 175.
- dioxide storage, 348.
- in soil, determination, Ky. 469.

Carbon—Continued.

monoxide asphyxia, effect on food intake and gastrointestinal peristalsis in rats, 459.

organic, distribution in soil, relation to aggregate size, 15.

Carcinogenic substances, chemistry and biological properties, 310.

Carnation—

- diseases in greenhouse, Wash. 222.
- pests, control, 393.

Carnations—

- cut, storage problems, 793.
- gravel culture in greenhouse, Ohio 519.
- onion thrips damage to, reducing, Wash. 239.

Carollinia cyperi, transmission of sugarcane mosaic by, 816.

Carotene—

- and vitamin A, 451.
- balance and blood-carotene levels in heifers and lactating cows, 267.
- changes in natural cured, artificially dried, and ensiled roughages, 703.
- feeding to cows, effects, 703.
- from bovine blood, determination with electric colorimeter, 832.
- in blood plasma of cattle, effect of pasture, 832.
- in fats, biological value, 598.
- in feeds, improved method for estimating, 330.
- in forage, determination, 330.
- in grasses, effect of drying methods, 256.
- in hay, effect of season, Okla. 96.
- in milk, determination, 269.
- in poultry feeds, factors affecting, Nebr. 689.
- in silage, determination, improved method, 83.
- intake, planes of, effect on health and longevity of rats, Tex. 141.
- of alfalfa leaf meal, stability in mixed ration, 695.
- relation to growth and well being of heifers, 703.
- requirements of dairy calves, Pa. 97.
- stability in green grasses and alfalfa stored at 5°, 256.
- utilization by rats, effect of oils, Ala. 140.

Carotenoid—

- and bile staining of fat in carcasses, distinguishing, 274.
- pigments, Ind. 613.

Carpenter worm, injury to shelterbelt plantings, N.Dak. 813.

Carpet grass, fertilizer tests, Fla. 200.

Carpocapsa pomonella, *see* Codling moth.

Carpophilus hemipterus, *see* Fruit beetle, dried.

Carrot—

- blight, control, Calif. 220.
- hypocotyl and roots, anatomy, 488.
- leaf blight, Tex. 52.
- rust fly, West.Wash. 391.

Carrots

- effect of copper sprays, Conn.[New Haven] 526.
- losses of vitamin C during boiling and steaming, 146.
- seed treatment for, Tex. 51.
- variety and strain tests, Pa. 40.
- variety tests, Pa. 374.

Casein, manufacture, improved methods for, Calif. 265.

Cassava—

- flour for substitute of wheat flour in bread making, preparation, P.R.Col. 469.
- poisonous, P.R.Col. 469.
- variety tests, P.R.Col. 502.

Castor-bean—

- insects, U.S.D.A. 805.
- lipase and its action, 5.
- lipase, effect of certain salts and cholesterol on activity, 5.
- nuclear size in differentiating spiral elements, 180.

Castor-bean tick—

- of British sheep, control, 276.
- of sheep, control, 402.
- of sheep, seasonal and annual incidence, 687.

Catabomba pyrastris, biology, morphology, and anatomy, 820.

Catalase test tubes, direct reading, types, 9.

Catalpa sphinx—

- attacked by *Apanites congregatus*, 672.
- tests with basic copper arsenate, 244.

Cataract, nutritional, cause and control, Mass. 591.

Caterpillars

- pest of *Michelia* in South Malabar District, 811.
- swarming, studies, 810.

Caterpillars of economic importance not previously recorded, 810.

Catholic rural problem in America, 447.

Cats, virus disease, acute and highly fatal, 284.

Cattle—see also Calves, Cows, Heifers, Live-stock, and Steers.

artificial insemination in, 497.

beef—

- effect of phosphorus deficiency, Calif. 254.
- fattening, carotene requirements, 402.
- fattening, rice byproducts and molasses for, value, La. 688.
- feeding experiments, Nebr. 404.
- in rice area, wintering, La. 688.
- Mandan grazing trial, N.Dak. 91.
- measuring performance in, comparison of methods, 497.
- range, production, effect of mineral deficiencies, Tex. 87.
- value of supplements to pasture for, Hawaii 687.

blood cells in health and during *Brucella* infections, 279, 280.

blood, spectrophotometric examination for carotene and vitamin A, 408.

Cattle—Continued.

breeding, blood calcium and phosphorus levels, effect of feeds, Nebr. 689.

breeding herd, winter grazing of corn and velvetbeans and green oats, returns, Ga.Coastal Plain 404.

Canadian, export markets for, 724.

dairy—see also Cows.

blood, inorganic phosphorus in, 266.

breeding for high production, N.Dak. 99.

breeding programs, effect of disease, 771.

carotene requirements, 404.

comparative returns from various pastures, S.Dak. 305.

diseases, 279.

effect of direct sunlight on, S.Dak. 265.

effect of restricted winter rations on blood calcium, phosphorus, and carotene, 703.

effect of vitamin A supplement, Mass. 700.

grazing on winter and summer annual crops, returns from, La. 700.

growth and reproduction, effect of vitamin A concentrates, Mass. 562.

inheritance of fertility in, 771.

institutional herds, increasing production in, 771.

nickings in, 497.

pasture most profitable feed source for, Miss. 825.

physiology, 412.

production records, application of age conversion factors to, 98.

reproduction, factors affecting, Oreg. 96.

reproduction in, effect of complex mineral and vitamin mixtures, Mass. 562.

reproductive efficiency, variations in, 264, 700.

roughages for, comparison of grasses, Hawaii 699.

roughages v. roughages and limited amounts of concentrates, Wash. 265.

selection, teaching, Ill. 861.

sterility in, relation to vitamin E, Iowa 95.

vitamin A requirements, Okla. 96, Tex. 97.

diseases, see specific diseases.

ectoparasites and blood parasites of, 892.

fattening, dried citrus peel and pulp meal for, Tex. 86.

fattening, financial results in, 435.

fattening, protein supplements for, S.Dak. 255.

fattening rations, different proportions of molasses and corn in, relative value, Okla. 85.

feces and urine, distribution of elements of fertility between, 402.

Cattle—Continued.

- feeding cull peas to, Wash. 255.
 feeding experiments, 404, Ind. 406.
 feeding experiments with bonemeal, 703.
 feeding, returns per acre in, Ohio 559.
 fever, southern, nature, cause, and prevention, 103.
 fluke-infected, treatment with Distol and Kamala, Hawaii 671.
 grub, bionomics, 683, 811.
 hard yellow livers in, Tex. 104.
 herd management and herd production, 357.
 Holstein-Friesian, effect of inbreeding, Iowa 27.
 Holstein-Friesian, white head in, inheritance, 771.
 hybrid baby beef, production, N.Dak. 558.
 industry, minimum price fixing in Argentina, U.S.D.A. 585.
 industry of Colombia, aid for, U.S.D.A. 854.
 Jersey, herd management and herd production, 563.
 liver abscesses in, bacteriologic study, 279.
 milk and butterfat production records of foundation cows and daughters sired by a proved sire, U.S.D.A. 771.
 mineral requirements, Tex. 88, 97.
 new recessive lethal in, 357.
 on grassland type range, nutritional studies, Ariz. 91.
 phosphorus deficiency in, Pa. 86, 98.
 plague, *see* Rinderpest.
 poisoning, *see* Plants, poisonous, and specific plants.
 prices, index number, N.Dak. 131.
 purebred *Bos taurus* and *Bos indicus* and their crossbred types, response to environment, 497.
 range, calcium and inorganic phosphorus in blood, N.Mex. 825.
 rations, mineral deficiencies in, Fla. 254.
 resistance to *Brucella abortus* after artificial infection, 281.
 Sahiwal breed, effect of skeletal alterations on milk qualities, 28.
 shipments into and from the State, Calif. 290.
 ticks, *see* Ticks.
 venereal infections, spread and eradication, 718.
 vitamin A and carotene requirements, Tex. 86.
 winter rations, protein supplements: comparison, Kans. 91.
 Yaroslav breed, blood value, 194, 507.
 yearling, fattening, protein requirement [N.Y.] Cornell 85.
 year-round grazing on succession annual crops in North Carolina, 257.
- Cauliflower—**
 boron deficiency in, Me. 40.
 breeding for resistance to black rot, N. State 222.

Cauliflower—Continued.

- household storage, 593.
 variety tests, Pa. 374.
 vitamin C in, effect of cooking methods and types of utensils, Fla. 300.
caulorchis skrjabini from rumen of cattle and buffaloes, 836.
 'cal fluke, intermediate hosts, Hawaii 671.
 'ceticis, chronic ulcerative, in rats, 279.
 'edar rust, *see* Apple rust(s).
 'edars, red—
 for semiarid conditions of western Kansas, 486.
 ornamental, spray trials, Mich. 536.
- Cherry—**
 blackheart, Fla. 221.
 blight pathogens, dissemination on clothing of farm laborers, 383.
 damping-off of seedlings, Fla. 221.
 diseases on New York market, U.S.D.A. 48.
 diseases, seed-borne, control, N.Y. State 222.
 early blight, control, Fla. 221.
 fertilization, Fla. 210.
 household storage, 593.
 leaf blights control, new fungicides for, Mich. 531.
 pink rot, control, Fla. 221.
 production and marketing, [N.Y.] Cornell 721.
 production on Everglades organic soils, fertility program, Fla. 314.
 quality, factors affecting, R.I. 787.
 salt injury to, U.S.D.A. 795.
 self-blanching types, breeding, [N.Y.] Cornell 41.
 variety and strain tests, Pa. 40.
 variety tests, Pa. 374, R.I. 788.
- Cell activity and changes of viscosity, 620.
- Cells—see also Plant cells.**
 goblet, and age resistance to parasitism, 104.
- Cellulose—**
 adhesive properties, 474.
 alpha, important byproduct from sugarcane, P.R.Col. 469.
 and aluminum oxide interfaces, electric moment of aliphatic alcohols, acids, and esters at, Minn. 469.
- Census methods, partial and sample, development of, 431.
- Census, trial, in 1938, developments from 431.
- Centipede grass, failure, cause, Fla. 221.
- Cephalosporium—**
 disease, hosts and distribution, 232.
 sp. on elms, 64.
- Cephenemyia pratti*, speed of, 683.
- Cerambycidae, Indian, biology and host plants, 685.
- Ceratitis capitata*, *see* Fruitfly, Mediterranean.
- Ceratoma catalpae*, *see* Catalpa sphinx.
- Ceratostomella—**
 sp. associated with *Ips lecontei* in Arizona, 390.

Ceratostomella—Continued.

on planetrees, U.S.D.A. 378.

ulmi—

eradication, scouting and sampling
elms as aid, 389.

in England, fructification, 359.

on American elm, relation to elm
borer, 390.

on elm specimens, tabulation,
U.S.D.A. 525.

resistance of elms to, 666.

Cercaria—

burti in leeches and ducks, development,
105.

new microphallid, description, 103.

Cercospora—

leaf spot of bananas, P.R.Col. 527.

leaf spots of peanut, dusts and sprays
for, Ga. 529.

nicotianae, notes, Ga.Coastal Plain 378.
sp., notes, Calif. 220.

undescribed species, mode of action of
bordeaux on, La. 656.

Cereal—

breakfast food proteins, egg-replacement
value, 306.

chemistry, modern, 470.

diseases, U.S.D.A. 378, 525.

diseases in California, U.S.D.A. 48.

diseases in Georgia, U.S.D.A. 525.

diseases in Oklahoma, U.S.D.A. 795.

diseases in Oregon, U.S.D.A. 655.

nursery seeders, 429.

proteins, milk replacement value in
adults, 305.

rusts, 526, U.S.D.A. 378.

rusts in Texas, U.S.D.A. 525.

seed treatment, *see* Seed treatment.

smut—*see also* Smuts and specific hosts.

fungi, susceptibility of forage
grasses to, 382, 657.

stem rust, effect of four years of bar-
berry eradication, 47.

Cereals—*see also* Grain and specific grains.

acid-base balance, 449.

and rickets, 262.

as source of vitamin B₁ in human diets,
875.

botany of, treatise, 18.

inheritance in, Wash. 222.

pests and parasites, 672.

root development, relation to root rots,
528.

snow scald, organisms causing, [N.Y.]
Cornell 49.

yield, Alaska, 362.

Cereba bubalus, *see* Buffalo treehoppers.

Cestodes—

encysted stage, distribution, 335.

from columbiformes, 570.

mammalian and avian, 570.

Cestorhynchus assimilis, notes, West.Wash.
391.*Chaetodacus*—

ferrugineus var. *dorsalis*, emergence of
larvae and pupae, 549.

Chaetodacus—Continued.

spp., heat sterilization of Formosan
fruits for, 550.

spp. in Fiji, 79.

Chalaza formation in eggs, mechanism, 261.

Chalcididae parasites of *Apanteles congregatus*, 672.

Chalcodermus—

aeneus, *see* Cowpea curculio.

bondari, notes, 253.

Changa parasite, establishment in Puerto
Rico, 686, P.R.Col. 541.

Chaparral in San Gabriel Mountains—

annual accumulation and creep of litter,
338.

forest floor of, 337.

Cheese—

B-1 Paese type, composition and manu-
facture, U.S.D.A. 415.

blue, ripening, lipolytic and proteolytic
activities of penicillia of, 702.

blue, use of steapsin in manufacture,
833.

brick, factors causing splitting, Wis. 97.

brick, milk and starters for, 272.

brick, predicting acidity, Wis. 97.

brick starters, controlling quality, Wis.
97.

Cheddar—

examination, smear culture technic,
702.

flavor development in, relation to
fat hydrolysis, 702.

loss of vitamin A in during curing,
Pa. 141.

rusty spot in, organisms causing,
102.

solubility of curd in sodium chloride
solutions, 102.

southern short-cure, quality, Tex.
97.

standards for rating, 702.

white particles in, 568.

curd, elastic and plastic properties, ap-
paratus for measuring, 102.

curing, bacteriological changes during,
Pa. 97.

efficiency of pasteurization, rapid phos-
phatase test for, 704.

factory price and average retail price,
Wis. 123.

foreign varieties, manufacture, ripening,
and development, Wash. 265.

industry of State, future of, N.Y.State
319.

Limburger, control of gas in, 706.

Limburger, surface flora, effect of pH
and salt, 706.

making, pasteurization of milk for, 271.

making, unsuitability of mastitis milk
for, causes, 566.

manufacture, starter cultures for, 568.

rinds, composition, 102.

Roquefort, identification, 272.

sales following sales campaign, Wis. 123.

salt content, determination, 166.

Cheese—Continued.

starters, lactic acid streptococci of, 702.
surface-ripened, improving quality, N.Y.
State 267.

Swiss—

bacteriology, Wis. 97.
grade, relation to quality of milk,
272.
heat resistance of subcultures, effect
of methods of handling thermo-
duric lactics, 103.
manufacture of a special-type, Iowa
96.
moisture content, effect on quality
and yield, 702.
starter cultures, activity and heat
resistance, 102.
starters, effect of time and tem-
perature, Wis. 97.

Oheliospirura—

centrocrot, new nematode from sage
grouse, 709.
hamulosa, notes, Hawaii 671.
spinosa, parasite of ruffed grouse, Mich.
805.

Chelidonium bresicorne, notes, 401.

Chemical elements, biological essentiality and
atomic structure, 182.

Chemurgy, research in, industrial fellowships
for, 605.

Chenopodium oil, properties and anthelmin-
tic value, S.Dak. 273.

Chermes, insect predators, life histories, 246.

Cherries—

cost of production, Mich. 235.
cracking, effect of different spray ma-
terials, Idaho 650.
maraschino, making at home, N.Y.State
449.
pollen tube growth in, 215.
rootstocks for, N.Y.State 213.
spray residue removal from, [N.Y.]Cor-
nell 43.
storage, effect of carbon dioxide and
volatile fungicides, U.S.D.A. 44.

Cherry—

bacterial canker, N.Y.State 800.
casebearer in Oregon, 680.
diseases, U.S.D.A. 525.
fruitfly, biology and control, 239.
fruitfly committee, report, 239.
fruitfly, white-headed, poisoned bait
spray for, 684.
fruitworm, Wash. 239.
fruitworm, life history and control, West.
Wash. 331.
gummosis, U.S.D.A. 525.
insects, control, N.Y.State 239.
leaf curl, effect of potash, 800.
leaf spot, control, N.Y.State 222,
U.S.D.A. 525.
leaf spot control, modified bordeaux
spray for, Wis. 527.
maggot, control, 539.
mottle leaf, Idaho 655.
scur, premature defoliation, causes, 533.

Cherry—Continued.

trees in Wenatchee-Okanogan District,
Wash. 587.
wild, X-disease on, U.S.D.A. 795.
X-disease, U.S.D.A. 655.

Chestnut—

blight, Conn.[New Haven] 526.
blight resistance, breeding for, 536.
trees, Asiatic, establishment, Ind. 653.
trees, pests in Greece, 71.

Chia, adaptability tests, Ga.Coastal Plain
374.

Chick—

antidermatitis factor, nature and partial
synthesis, 695.
comb test for assaying male sex hormone,
197.
embryo, pigmentation in, study, 192.
rations, cereals and oat hulls in, ef-
fect on cannibalism, West.Wash. 404.

Chicken—

body louse, nicotine for control, Ky. 540.
head louse, notes, Ky. 540.
louse, large, nicotine for control, Ky.
540.
pox, early vaccination of chicks against,
Miss. 834.

Chickens—*see also* Chicks, Fowls, Hens, Poul-
try, and Pullets.

broiler production, Del. 254.
broilers, cost of winter production, Ind.
721.
broilers, cottonseed meal for, Miss. 825.
chilling and freezing treatments, effect
on palatability and tenderness, Iowa
140.
frozen, cooking studies with, 736.
market quality and consumer value, fac-
tors affecting, 697.
palatability studies of meat, 737.

Chicks—

and chick embryos inoculated with
rabies virus, 418.
body temperature, variability, 93.
calcium and phosphorus requirements,
Tex. 87.
gizzard erosion and growth, effect of
chondroitin sulfuric acid on, 263.
gizzard erosion in, chondroitin as pre-
ventive, 94, Wis. 87.
gizzard erosion in, effect of bile acids
on, 409.
gizzard lesions in, nutritional, Mass. 560.
growth and nitrogen retention, efficiency
of protein supplements, Iowa 84.
growth rate, genetic influence, Ind. 698.
manganese requirement for bone develop-
ment, 560.
market quality, relation to body confor-
mation, Okla. 85.
optimum amount of salt for, Nebr. 689.
protein feeds for, comparison, Tex. 93.
protein levels in rations, Del. 254.
protein reduction in rations, Ind. 688.
protein requirements, Wash. 255.
size, growth rate, and viability, effect
of protein level, Okla. 85.

Chicks—Continued.

skeletal development to six weeks of age, 409.

slipped tendon in—

blood and bone phosphatase of, 694.

effect of proteins and inorganic elements in ration, Iowa 84.

histopathological changes occurring in, Wis. 87.

interrelations of manganese and phosphorus, Wis. 534.

prevention methods, Okla. 85.

relation to availability of manganese, 410.

role of manganese and rice bran in prevention, Wis. 87.

severity, effect of mineral salts, 261.

studies, Tex. 87.

utilization of energy of feed, Nebr. 93, 409, Tex. 408.

variation in reaction to methods of administering androgens, 197.

vitamin requirements, Tex. 87.

vitamin A requirements, N.H. 94.

vitamin B₁ deficiency, Wis. 87.

Children—see also Girls and Infants.

blood plasma values of vitamin C in health and disease, 314.

energy metabolism, effect of tea, Tex. 141.

food habits and nutritional status, Me. 140.

in Citrus County, nutritive status, Fla. 301.

Indian, calorie requirements, 309.

school, body measurements, Tex. 309.

school, physical fitness, judging, 870.

with abnormal bodily dimensions, basal metabolic rate, 310.

Chilo plejadellus, see Rice stalk borer.

Chilo simplex, see Rice borer, Asiatic.

Chimeras, periclinal, induction in *Datura stramonium* by colchicine treatment, 620.

Chinch bug—

bionomics and control, Iowa 66.

control, Nebr. 672.

immunity in sorghum, relation to composition, 182.

problem, Okla. 68.

Chipmunks, susceptibility to virus of endemic typhus fever, 279.

Chirothrips, American species, synopsis, 816.

Chlorate—

herbicides, studies, Calif. 200.

in soil extracts, culture solutions, and plant sap, determination, 6.

Chlorella photosynthesis—

quantum efficiency, 180.

role of magnesium in, 181.

Chloride in milk, 101.

Chlorophyll—

and vitamin C, 146.

crude, in cane leaves, composition, 733.

deficiencies in red clover, genetics of, 494.

estimation, 181.

function, 181.

in leaves, condition, 628.

Chloropierin—

for soil fumigation, methods of applying, 209.

for soil sterilization and nematode control, 224.

growth retardation by, R.I. 760.

treatment on compost and seedbed soil for weed seed control, R.I. 775.

Chloroplast nitrogen of plants, 21.

Chloroplasts from plants, quantitative isolation, 20.

Chlorosis—

affecting ornamentals, manganese sulfate as corrective, Fla. 210.

in beans followed by wilt and death of plant, 663.

in coffee trees, soil alkalinity as indirect cause, P.R.Col. 527.

in corn and other crops, Fla. 221.

in cottonwoods, treatment, 526, Wyo. 527.

in gardenias, factors affecting, 335.

in macadamia nut, Hawaii 644.

in peach, role of magnesium in, 795.

in plants, treatments for, N.Mex. 795.

lime-induced, studies, 800.

Chocolate—

meal, value for poultry, Calif. 254.

samples, lead in, Mass. 591.

varieties, consumer preference for, 701.

Choerostrogylus in pigs, course of infection, 836.

Cholera in ducks, value of chemically killed cultures for, 114.

Cholesterol fed to guinea pigs, anemia caused by, 748.

Choline—

action on liver of fat-fed rat, mechanism, 690.

chloride, effect on oestrous cycles in mice, 32.

deficiency in diets of rats, effect, 869.

Chondroitin—

as growth factor for chicks, 84.

for preventing gizzard erosion in chicks, 94, Wis. 87.

sulfuric acid as growth factor, 405.

sulfuric acid, effect on gizzard erosion and growth in chicks, 263.

Choriomeningitis, lymphocytic—

and canine distemper viruses, simultaneous occurrence, 846.

transmission by mosquitoes, 571.

Chorioicetes terminifera causing plague in Australia, 244.

Chromium, copper, zinc, and molybdenum, comparative nutritive effects, Mass. 477.

Chromosomes—

alterations, heritable variations conditioned by, 191.

breakage and reattachment, growth changes associated with, 190.

in corn and other plants, number, form, and behavior, role in heredity, [N.Y.] Cornell 84.

measurement of packing and contraction in, 464.

Chromosomes—Continued.

- number in hybrid wheat, somatic variation, 26.
- rate of movement on the spindle, 464.
- sauropsid, studies, 498.
- specialized particle, centromere, functions, 634.
- structure, developments in knowledge of, 494.

Chrysanthemum Verticillium disease, control, 233.

Chrysanthemums—

- effect of photoperiod modification, Ala. 39.
- gravel culture in greenhouse, Ohio 519.
- new, descriptive notes, U.S.D.A. 519.
- photoperiodism, [N.Y.]Cornell 45.

Chrysobothris femorata, see Apple tree borer, flatheaded.

Chrysoclista atra in apple plantations of England, 396.

Chrysomphalus aurantii, see Red scale, California.

Churches, rural, survey in Cortland County, [N.Y.]Cornell 132.

Ciurn, rollerless, 701.

Cicadula divisa, see Leafhopper, six-spotted.

Cinco—

- lectularius*, see Bedbugs.
- structural hybridity in, 464.

Cineraria leaf miner, damage to parks and private gardens, 79.

Cinnamic acid, activation by ultraviolet light, 351.

Cirphis unipuncta, see Armyworm.

Citrus—

- boron deficiency in, symptoms, 182.
- breeding, Fla. 210, Tex. 41.
- byproducts for poultry, Fla. 255.
- canker, discovery in New Zealand, U.S.D.A. 48.
- culture and storage, Tex. 41.
- deficiency symptoms in 801, Fla. 501.

- Clastoneurlopsis* n. g. and n. sp., notes, 820.

Claviceps paspali—

notes, Hawaii 655.

Paspalum spp. as hosts, 56.

Clay, use for clarification of sorghum sirup, development, Iowa 4.

Clematis, propagation, Mass. 512.

Clemson College, notes, 891.

Climate—see also Meteorology.

and agriculture in California, 332.

in West Africa, effect of vegetation, 617.

Climatic research in Soil Conservation Service, U.S.D.A. 169.

Climatological data, U.S.D.A. 168, 336.

Climax vegetation, review, 436.

Clitocybe tabescens, notes, Fla. 221.

Clostridium—

botulinum toxin and American vultures, 114.

botulinum type A toxin infecting foxes, 284.

chauvei, culture medium for production of blackquarter vaccine, 837.

infection in turkeys, 579.

spp., accessory growth substances for, 352.

Clothes moth, webbing, nutritional studies, 77.

Clothes moths, biology and control, [N.Y.] Cornell 66.

Clothing, women's, consumer demand in, Mo. 885.

Clove trees, borers in, 401.

Clove trees, longicorn stemborer in Dutch East Indies on, 552.

Clover—

adaptation studies, Hawaii 638.

alsike, insect pollination, 807.

alsike-timothy-sweetclover as hay mixture, merits, Wis. 502.

bur, variety tests, Tex. 37.

crimson, for forage and soil improvement, Okla. 35.

effect of nurse crops, Idaho 638.

establishment and survival effect of fertilizers and oak ashes, Tex. 37.

fertilizer experiments, Fla. 200.

Ladino—

fertilizer experiments, Calif. 199.

for western Oregon, Oreg. 38.

nurseries for improvement, West. Wash. 363.

production tests, R.I. 775.

red, alfalfa, and sweetclover, relative value as soil-building crops, Iowa 34.

red, breeding, Pa. 35.

red, chlorophyll deficiencies, genetics of, 494.

red, cuttings, rooting, tests of plant hormones for, 363.

red, failure, factors causing, Conn. [New Haven] 501.

red, foreign v. American and Canadian yields, Wis. 502.

red, inheritance studies, Pa. 35.

red, strains, soil acidity tolerance, Pa. 36.

Clover—Continued.

red, variety tests, Iowa 33, Ky. 501.

response to different fertilizer treatments, Ind. 638, La. 639.

response to liming, Ky. 501.

root nematode, control, Oreg. 50.

stem rot, U.S.D.A. 220.

strawberry, new variety, Oreg. 35.

Subterranean, rates of phosphate on, Tex. 37.

sweet, see Sweetclover.

variety tests, Fla. 200, Tex. 36.

white, prevalence in grassland, 641.

white, value in pastures and response to treatment, Wis. 502.

Club work, see 4-H club.

Clubhelia longana, see Strawberry fruit-worm.

Cobalt—

effect on pine disease in sheep, 250.

in nutrition, 405.

requirement of animals, Wis. 87.

Coccarboxylase synthesis, role of vitamin B₁ in, Wis. 142.

Coccid moth, Fla. 238.

Coccidia of rabbit, effect of X-ray on, 700.

Coccidian—

oocysts in poultry houses, efficiency of blowlamp for destruction, 848.

periodicity, role of host activity in, testing, 104.

Coccidiosis—

avian, transmission experiments, Wyo. 569.

control by sanitation, West. Wash. 424.

in chickens, effect of diet, Iowa 103.

in chickens, species involved, Oreg. 285.

in chickens, use of milk flush for, West. Wash. 424.

in chicks, mortality from, relation to dried milk products in ration, 104.

in chicks, treatment with sulfur, Wis. 104.

in crows, 836.

in herds of cattle, 713.

in lambs, effect of ferric sulfate and copper sulfate, 574.

in muskrats, effect of water levels, 364.

in rabbits, control, U.S.D.A. 668.

notes, Oreg. 103.

Coccids of Madeira, 539.

Coccinellids of Punjab, 809.

Coccinia indica fruits, pest of, 810.

Coccus hesperidum, see Scale, soft.

Coccus viridis, see Scale, green.

Oochilomyia—

americana, see Screwworm.

macellaria, see Screwworm, secondary.

Oochlonema spp., description, 183.

Cockereels, preservation of sperm life in vas deferens, effect of testis hormone, 32.

Cockroach—

American, biology, 678.

American, blood cell structure and degeneration, N.H. 73.

German, nutritional requirements, 73.

Cockroaches—

six species, life history and habits, 807.
studies, Ind. 672.

Cocks and cockerels, crossbred, semen production, 32.

Cocoa—

bacteriological properties, Mass. 562.
moth larvae, bacterial flora in gut, 811.
samples, lead in, Mass. 591.
structure and composition, 142.

Coconut—

beetle in South India, 811.
leaf miner, Javan parasite of, 69.
palm beetle, biology, 822.
scale in tea regions, 392.
treehoppers, 395.

Coconuts—

cultivation in Cochín State, insect problems affecting, 810.
new dwarf, studies, P.R.Col. 512.
notes, 211.

Codling moth—

bait traps, use as extension project, 806.
bionomics and control, Del. 238, Iowa 65.
control, 76. 671. Idaho 671. Pa. 50, 70.
control, baits and bait traps in, Va. 819.
control by trap bands, 539.
control, effect of neutral copper compounds on tank-mix-nicotine-bentonite, 680.

control, experiments with nicotine, 548.
control, first brood, theory and practice, 813.

control, importance of following spraying recommendations, Wis. 541.

control, papers, 808.

control, recent studies and trends, 813.

control, sprays for, Wash. 239.

control, timing of sprays for, Pa. 68.

control with cryolite and new procedure for application, 808.

control with electric traps, Ind. 720.

distribution, status, and biology in Baluchistan, 547.

experiments, 69.

false, pest of citrus in South Africa, 815.

injury to Williams pears, control, 76. 77.

insecticides, 813.

insecticides, field comparisons of, N.Mex. 387.

larva, toxicity of derivatives of benzene containing halogen and nitro groups to, 250.

larva, toxicity of insecticides, effect of particle size on, 548.

larvae, newly hatched, distances traveled by, 670.

larvae, trapping with treated corrugated paper bands, 681.

life history and control, new developments, 806.

new microsporidian parasite, 82.

notes, 393, Ind. 671, Ky. 540.

second-brood, on walnuts, Calif. 238.

situation in Missouri, 542.

Codling moth—Continued.

sprays, 547, 548, Wis. 541.

studies, N.Mex. 808.

worms, distribution on apple trees as affected by banding, 680.

Cod-liver oil injury in Herbivora, [N.Y.] Cornell 85.

Coffee—

bean, toxicity for sheep, 843.

berry borer in Ceylon, 400.

blossoms, abscission, P.R.Col. 512.

culture and pruning, Hawaii 644.

farms, disease survey, P.R.Col. 527.

insect enemies in New Guinea, 393.

Institute, National, of Venezuela, reorganization, U.S.D.A. 292.

leaf-miner, studies, P.R.Col. 541.

plant, effect of light intensity on, P.R. Col. 512.

plantations, management, P.R.Col. 512.

production practices in Puerto Rico, P.R.Col. 651.

propagation and fertilizers for, P.R.Col. 512.

quality in, Hawaii 644.

root rots, P.R.Col. 527.

roots, growth habits, P.R.Col. 512.

stomata in, relation to chromosome number, 765.

structure and composition, 142.

trees, composition, effect of fertilization, Hawaii 644.

Colchicine—

amphidiploids in Triticinae induced by, 191.

cytogenetic results with, 189.

effect on chromosome number and cell size in plants, 355.

effect on generative cell in pollen tubes of *Lilium*, 180.

immediate effects, 189.

in prevention, inhibition, and death of plant tumors, 53.

properties and effects, development of knowledge about, 189.

reactions in ventral prostate of castrated male rats, 773.

treatment, induction of diploids from haploids by, 190.

treatment, induction of polyploidy by, 190, 770.

treatment of *Datura stramonium*, effect on chromosomes, 190.

use in including fertility in intergeneric hybrids, 27.

Cold storage—

locker plants, Wis. 123.

lockers, community, meat storage in, Wash. 255.

lockers, preservation of fruits and vegetables in, N.Dak. 142.

plants, locker and home, engineering aspects, 120.

Coleophora maltivorella, see Pistol casebearer.

Coleophora pruniella, see Cherry casebearer.

Coleoptera—

development, 809.

Coleoptera—Continued.

identified in pellets of little owl, 67.

in raisin storages, 821.

wood-boring, nutrition, 685.

Colaspium crowellii, studies, U.S.D.A. 375.

Coli-aerogenes group in milk, detection, Pa. 97.

Collards—

available iron in, 596.

fertilizer placement, Va. Truck 788.

College students, American-born Japanese, basal metabolism, 871.

Colleges, see Agricultural colleges.

Colletotrichum dieback of coffee, P.R. Col. 527.

Colloids—

in the sugar mill, classes of, 331.

of Cecil and Susquehanna soil profiles, comparison, 341.

soil, and plant roots, cation interchange between, 187.

Collops quadrimaculatus, important enemy of chinch bug, Okla. 68.

Coloborhombus fasciatipennis, notes, 401.

Culophia graminis on elms, Fla. 238.

Colorado College, notes, 320, 752.

Colorado Station, notes, 320, 752.

Colts, production, Iowa 84, Miss. 825.

Combine harvester-thresher—

costs, Ind. 721.

studies, Ind. 720.

Combines, small, harvesting with, economic study, Ind. 852.

Community association plan, standard, of Missouri, 447.

Composite thrips, biology, habits, and distribution, Calif. 245.

Concrete—

curing materials, tests, U.S.D.A. 851.

pavements, structural design, application of research to, U.S.D.A. 851.

reinforcement, looped wire for, Colo. 852.

Knives—

drought resistance, effect of moisture supply, 793.

embryogeny in new type, 347.

mycotrophy of, 487.

northern, soil-fertility standards for growing in forest nurseries, 46.

phloem structure and development, 765.

propagation, [N.Y.] Cornell 45.

Connecticut—

[New Haven] Station, report, 157, 603.

State Station, notes, 159, 605.

Storrs Station, fiftieth anniversary program, 461.

Storrs Station, notes, 320, 889.

Storrs Station, report, 887.

University, notes, 320, 889.

Oenoderes spp. in bluegrass sod, Ky. 821.

Oenopia celtica, see Peach borer.

Oenotracheus nemophar, see Plum curculio.

Consumer education, bibliography, 886.

Contact angles, determination and application to studies on wetting, 469.

Contarinia juniperina n.sp., description, 682.

Cooking with various sources of heat, comparative costs, Wash. 287.

Cooperation, American, 442.

Cooperative—

association, farmers', organization, 725.

fluid-milk associations in Iowa, 443.

grain elevators, accounting procedure, 725.

grain elevators in Kansas and Oklahoma, operations, 725.

purchasing in Washington, Wash. 588.

purchasing through Illinois Farm Supply Company and member companies, 443.

societies of Mexico exempt from tax payments, U.S.D.A. 432.

Cooperatives—

farmers', statistical handbook, 442.

in agriculture, 443.

in South Dakota, S.Dak. 443.

optimum rate of growth, 430.

Cooperia curticei, life history and development of resistance in sheep, 570.

Copper—

action on leaves, 353.

alloys, rates of corrosion in milk and effect on flavor, 701.

arsenate, basic, as new insecticide, 243.

contamination of butter, 704.

essentiality for plants, 630.

fungicides—

development and use, 527.

effect on lead-arsenate-lime and fixed nicotine-oil sprays for codling moth, 548.

neutral, effect on tank-mix nicotine-bentonite for codling moth control, 680.

relation to lead arsenate-lime and fixed nicotine-oil sprays, 224, 539, 671.

in butter, 702.

in fruits and vegetables, Mass. 469.

in Philippine foods, 306.

in soil fertility and plant nutrition, Oreg. 17.

injury to lima bean foliage following insect injury, Fla. 221.

oxide, red, as foliage fungicide, N.Y. State 222.

role in plant nutrition, 352.

sprays on vegetables, Conn. [New Haven] 526.

sprays, toxicity to *Actinonema rosea* spores, effect of weathering, Tex. 51.

zinc, chromium, and molybdenum, comparative nutritive effects, Mass. 477.

Coprinus urticaceus on Marquis wheat, 528.

Copris incertus procioides, notes, P.R. 250.

Coptocercus biguttatus, notes, 401.

Copulatory activity in male rats following castration and injections of testosterone propionate, 361.

Cordylopa spp. in central Pennsylvania, 52.

Corn—

adaptation studies, Nebr. 368.

adaptations and field practices in Massachusetts, Mass. 365.

agricultural and industrial demand for, effect of imports, Iowa 222.

Corn—Continued.

- and-rob and shuck meal for steer fattening rations, Fla. 254.
 and grain sorghum, interplanting, effect, Tex. 37.
 and hybrids, breeding, Conn.[New Haven] 501, Ky. 501.
 and kalo in chick ration, comparison, Nebr. 409.
 and sorghum, comparison, Tex. 37.
 and wheat futures, relation, 584.
 arrested axillary shoots and secondary ears in, *Basisporium galliarum* in, 660.
 bacterial stalk rot in Kentucky, U.S.D.A. 795.
 bacterial wilt, micro-evolution of host parasite interactions in, 47.
 bacterial wilt resistance in, genetic of, Iowa 48.
 Belt droughts of 1930, 1934, and 1936, 476.
 borer, European—
 biological control, status, 807.
 control, N.Y.State 239.
 control by *Beauveria bassiana*, 818.
 control by resistant strains and time of planting, Ohio 398.
 control, insecticides for, Mass. 540.
 electric traps as possible control for, Ind. 720.
 in Indiana, 806.
 in Java, 393.
 increased importance, N.Y.State 349.
 number per infested corn plant, relation to percentage of plants infested, 681.
 parasites, technic and equipment for handling to prolong hibernation, U.S.D.A. 242.
 partial second generation in Lake States, 249.
 second generation in Indiana, 819.
 situation in Lake States area, 806.
 studies, Conn.[New Haven] 540, Ind. 671.
 borer, southwestern, Tex. 66.
 breeding, Fla. 200, Ga.Coastal Plain 363, Nebr. 363, 639, N.Y.Cornell 34, Okla. 35, P.R.Col. 502, S.Dak. 201, Tex. 37.
 breeding, probable eventual effect on technic of livestock breeding, 26.
 broken ear, for steer fattening rations, Fla. 254.
 budworm, S.C. 69.
 byproducts, fermentation products formed by action of fungi on, Iowa 49.
 changes in technology and labor requirements, 433.
 characteristics, relation to industrial use, Iowa 4.
 check planted, hill spacing, Iowa 115.

seed, production, U.S.D.A. 506.

seed treatment, N.J. 529, N.Mex. 775.

seed treatment, response of plant and pathogens to, Iowa 49.

seedbed preparation and planting tests, La. 639.

seedlings, *Penicillium* injury, soil factors in, 54.

side dressing, comparison of nitrogen sources, La. 363.

silage, *see* Silage.

smut resistance, studies, Iowa 49.

smut, spectral sensitivity of spores and sporidia to monochromatic ultraviolet light, 180.

soundness in, chemical determination, U.S.D.A. 8.

spacing tests, La. 363, 639.

Stewart's disease, *see* Corn bacterial wilt. storage and curing, Iowa 115.

strains, stomatal behavior and rate of photosynthesis, [N.Y.]Cornell 18.

sugar and starch products from, Iowa 166.

supply and price, effect of Agricultural Adjustment Act, Iowa 292.

sweet, *see* Sweet corn.

tetraploid, notes, [N.Y.]Cornell 34.

translocations involving chromosome 8, 358.

under various fertilizer treatments, foliar diagnosis, 365.

use in fermentation industries, Iowa 292.

v. corn with soybeans, La. 363.

varieties and hybrids for different soils, Ind. 638.

varieties of Iowa, stem and root development, Iowa 18.

varieties, yield tests, Del. 200.

variety, adequate representation, number of top-crossed plants for, 365.

variety tests, Alaska 362, Fla. 200, Ga. Coastal Plain 362, Ind. 773, Me. 34, Ky. 501, La. 363, 639, Miss. 774, Nebr. 363, 639, N.Mex. 775, Okla. 35, Pa. 35, R.I. 775, S.C. 36, Tex. 36, Utah 641, Wash. 201, Wyo. 503.

wet-milling industry, effects of t. pioza and sago imports, Iowa 292.

Corn—Continued.

- winter cover crops, Ga.Coastal Plain 363.
- yellow, odor of, identification of compounds responsible for, Iowa 4.
- yields and land valuation, Iowa 345.
- zygotie lethal in chromosome 1 and link age with neighboring genes, 356.
- Corncoals, alkali lignin from, dehydrogenation with selenium, 5.
- Cornea of rat, vascularization in riboflavin deficiency, 311.
- Cornell University, notes, 463, 891.
- Cornstalk land, plowing v. disking for oats and barley, Nebr. 640.
- Cornstalks, methods of disposal, effect on yields of corn and oats, Ind. 778.
- Cornstarch—
 - industrial uses, Iowa 166.
 - oxidation, Iowa 4.
- Corpus luteum—
 - maintenance in rabbit by injection of oestrogenic hormone, 360.
 - stimulating substance in rat placenta, 197.
- Corrodentia as pests of ground feed, 670.
- Corticium microscerotia* n.comb, description, 531.
- Corynebacterium*—
 - equi* in buffalo-cow, 837.
 - genus, cultural characteristics, 274.
 - lower limits of genus, relation to *Proactinomyces*, 621.
 - pyogenes*, notes, 279.
 - sp. from lesions in goats and sheep, 110.
- Coryneum*—
 - blight of arborvitae, Oreg. 50.
 - cardinale* n.sp., description, 64.
- Coryza*—
 - infections, R.I. 834.
 - infections, of chickens, Calif. 273, Wyo. 569.
 - inheritance of resistance to, Wyo. 554.
 - of chickens, type III, 707.
- Cosmoglyphus* sp. in silage and Hly of the valley, 808.
- Cuscuta* *sordida*, see Banana root borer.
- Cost of production, see specific crops.
- Cotton—
 - Acacia, irrigation tests, N.Mex. 775.
 - acclimatization of exotic varieties in Sind, 205.
 - and corn in rotation, nitrogen carriers for, Ala. 33.
 - angular leaf spot, distribution and persistence under irrigation, 634.
 - anthracnose, new, in Manchukuo, danger from seed importations, 796.
 - aphid predator, biology and morphology, 78.
 - area of Texas, farm organization and operation, Tex. 292.
 - boll disease, internal, 69.
 - boll, enlargement, 180.
 - bolts, internal temperatures, 182.
 - bolts, partially damaged by bollworm, effect, 811.

Cotton—Continued.

- borer beetles, parasites of, 401.
- breeding, Ga.Coastal Plain 363, La. 689, N.Mex. 775, Okla. 35, P.R.Col. 502, S.C. 36, Tex. 37.
- breeding and insect pests, 70.
- breeding and seed supply, 365.
- breeding improved strains suited to local conditions, 206.
- breeding in India, 205.
- Broach Palej, deterioration on storage, 205.
- burs or bur ashes, fertilizing constituents, effect on crop yields, 179.
- changes in average staple length, S.C. 122.
- changes in technology and labor requirements, 433.
- classification, floral anatomy as aid, 206.
- cleaning, effect on lint quality and ginning efficiency, U.S.D.A. 288.
- composition of bark and inner part of roots, 778.

- trap crop for bollweevil emergence, S.C. 69.
- Uppam and Karunganni, effect of X-rays on, 206.
- varieties adapted to mechanical harvesting, development, Tex. 37.
- varieties, fruiting studies, Okla. 35.
- variety tests, Ga.Coastal Plain 362, La. 363, 639, N.Mex. 775, Okla. 35, S.C. 36, Tex. 36.
- variety tests, five-year summary, Miss. 774.
- Verticillium* wilt, control, 654.
- watering experiments, 205.
- whitefly as vector of tobacco leaf curl disease, 811.
- wild species and hybrid, morphology, 356.
- wilt disease, relation to varieties and fertilizers, Ala. 33.
- wilt due to *Fusarium vasinfectum*, S.C. 50.
- wilt-nematode experiments, 654.
- wilt resistance, breeding for, 205.
- wilt resistance, effect of mineral nutrition, S.C. 50.
- winter cover crops for, Ga.Coastal Plain 363, La. 639.

Cotton—Continued.

X-rayed seed for root rot control, Tex. 52.

yields and returns to labor and management, Tex. 122.

yields following different crops, La. 363.

Cottonseed—

cake and prairie hay, ineffectiveness for wintering beef heifers, Tex. 87.

cake as supplement for range lambs pastured on low-yielding corn, Wyo. 554

cake, hardness, Tex. 87.

coat, structure of chalazal portion, relation to rupture during ginning, 642.

delinted, gravity grading, Okla. 50.

for planting purposes, treatment, Tex. 116.

from green plants and from plants killed by root rot, analysis, Tex. 51.

meal and hulls as ration for milking cows, Tex. 97.

meal as concentrate for fattening yearling steers, N.Mex. 825.

meal for hogs, tests, Miss. 825.

meal injury, prevention, Okla. 96.

normal and treated, permeability of testa, 654.

oil content, Ala. 33.

planting at variable and uniform depths, Tex. 116.

prices, effect of quality, volume, and distance from market, Okla. 122.

storage experiments, S.C. 36.

treated with organic mercury dusts, effect of period and type of storage, 654.

treatment, 654, N.Mex. 775, S.C. 50, U.S.D.A. 227, 525.

viability, effect of moisture and age under different methods of storing, 366.

viability, effect of seed treatments, Tex. 51.

Cottony cushion scale—

notes, Tex. 67.

predator, maintenance of supply, P.R.Col. 541.

Cotylophoron cotylophorum—

life history, pathogenicity and biological control, 714.

of Indian ruminants, life history, 837.

Country, *see* Rural.

Cover crops—

culture experiments, Fla. 200.

for apple orchards, Del. 210.

notes, N.Y.Cornell 42.

value in erosion control, Calif. 169.

variety tests, Fla. 200.

winter, comparison, La. 639.

winter, culture experiments, Ga.Coastal Plain 363.

winter, variety tests, Ga.Coastal Plain 363.

suc content, 226.

Cowpea—

curculio, life history and control, 686, Ala. 65.

Cowpea—Continued.

curculio, notes, S.C. 68.

diseases in Oklahoma, U.S.D.A. 795.

hay, time for cutting, Miss. 775.

pod, green, fumigation, Fla. 238.

Cowpeas—

and soybeans in rotation for summer cover and green manure, Fla. 200.

as soil-building crop, Calif. 200.

breeding, Calif. 199, Tex. 37.

productive varieties or strains, Calif. 200.

resistance tests to root rot, Tex. 51.

variety tests, Fla. 200, Ga.Coastal Plain 363, La. 639, N.Mex. 775, S.C. 36, Tex. 36.

Cows—*see also* Cattle and Heifers.

affected with group-B streptococci, detectable antibodies in sera of, 713.

beef, winter ration, silage v. cottonseed hulls in, S.C. 86.

beef, wintering, Ky. 553.

dairy, artificial insemination of, 771, Mo. 773.

dairy, effect of feeding roughage to, R.I. 854.

dairy, effect of heat on, Calif. 265.

dairy, milk production and body weight, effect of liver flukes, Hawaii 671.

effect of changing from silage ration to pasture and vice versa, S.C. 97.

effect of fasting and refeeding on milk production, heat production, and respiratory quotient, Mo. 99.

failure of pregnancy, effect of Prognon-B in combating, [N.Y.]Cornell 27.

feeding, limited grain v. sole roughage, Wyo. 562.

heavy milking, effect of maintaining solely on alfalfa hay and pasture, Wyo. 562.

Holstein, on roughage rations, dry matter consumption, 264.

lactating, composition of blood and milk during inanition, 100.

lactating, mineral requirements, 266.

milk production, *see* Milk production.

milking, open-shed v. stable, Wyo. 562.

mixed Simmental, milk production, 892.

nutritive value of home-grown hay and silage rations, Wash. 265.

of unknown producing ability, relation between conformation and anatomy, 99.

on all roughage rations, nutrient requirements, comparison with nutrient consumption, 264.

producing dairy, water consumption, effect of temperature changes, 703.

records, *see* Dairy herd records.

shortening winter feeding period with reserved permanent pasture, S.C. 86.

shy breeding, effect of administration of gonadotropic hormones, Wis. 28.

twenty-five dollar, value of spring calves from, Miss. 825.

Cows—Continued.

ultraviolet radiation, effect on agglutinin titer for Bang's disease, 702.
vitamin D deficiency, 703.

Coyote, host to *Physaloptera felidis*, 571.

Crab apples—

ornamental, breeding, N.Y. State 213.
prices and income from, Mich. 294.

Crabgrass, control in Kentucky bluegrass lawns, Mass. 502.

Crackers, keeping quality, effect of anti-oxygen, 10.

Crambus caliginosellus, see Corn root web worm.

Cranberries—

fertilization and irrigation, Wash. 211.
flower and fruit production, Mass. 512.
preservation and food value, Mass. 591.
storage studies, Mass. 579.

Cranberry—

bog weeds, control, Mass. 502.
bogs, effect of September 1938 hurricane, Mass. 512.
bogs, frost protection, Mass. 579.
false blossom resistant strains, Mass. 527.
fruit rot, control by spraying, Mass. 527.
fruitworm, Mass. 540.
weevil, Mass. 540.

Crawfish—

control, Miss. 808.
of Mississippi, biology and control of destructive species, 237.

Cream—

and milk testers, manual for, Md. 268.
consumption in urban and rural Canada, 437.
cooling, effect on quality of butter, Okla. 96.
efficiency of pasteurization, rapid phosphatase test for, 704.
fat emulsion, stability, Mass. 562.
fat globules, adsorption membrane around, properties, 833.
frozen, changes occurring in storage, Mass. 562.
homogenization, low pressure, Pa. 97.
keeping quality, factors affecting, 832.
lipase activity in, relation to temperature of separation, Wis. 97.
market, factors affecting supply, Mass. 585.
market, viscosity, 701.
marketing studies, Ind. 699.
pasteurization for butter making, use of phosphatase test, 271.
preservation with salt, 271.
quality and butter quality, correlation, Wash. 285.
sediment tests for, Iowa 96.
separator, multiple-purpose, efficiency, Mass. 562.
sweet and sour farm-skimmed, enzymes in, relation to keeping quality of butter, Ind. 699.

Cream—Continued.

whipped, properties, factors affecting, Mass. 562.

Creameries—

cooperative, volume of business and cream data, Iowa 121.
Mid-West Producers', patronage problems, 443.

Crenosomatosis of silver foxes, treatment, 835.

Cress, hoary, anatomical development, 24.

Cricetidae, parasites of, 106.

Cricket—

Conlee, identification, U.S.D.A. 806.
greenhouse stone, control, 679.
mole, control, 816.
Mormon, control, U.S.D.A. 805.
Mormon, identification, U.S.D.A. 806.
Mormon, sodium arsenite used for, factors in, Mont. 394.
northern mole, Tex. 66.
southern mole, Tex. 66.
tree, life history, habits, and control on pear, 393.

Oriocoris asparagi, see Asparagus beetle.

Cronartium ribicola, see White pine blister rust.

Crop—

plants, botany of, treatise, 18.
plants, breeding resistance races, 634.
production, labor requirements for, 434.
reports, U.S.D.A. 132, 296, 444, 727 860.
residues, manurial value on Clermont silt loam, Ind. 638.
rotations, see Rotation of crops.

Cropping systems suggested for northwestern Oklahoma and climatic conditions, Okla. 616.

Crops—see also Forage crops and specific kinds.

adaptation on muck soils, [N.Y.] Cornell 42.
artificial drying, bibliography, U.S.D.A. 423.
boron deficiency symptoms in British Columbia, 220.
carotenoid pigments in, relation to nutritive properties, Ind. 688.
cold resistance in, nature, Nebr. 623.
composition, Iowa 13.
effect on succeeding crops, Ind. 773, R.I. 775.
field and pasture, comparative yields, 703.
forcing in commercial greenhouses, use of electric illumination for, Ind. 720.
green manure for, Tex. 37.
growing with pump irrigation, Nebr. 640.
growth and maturity, relation to organic composition, Fla. 170.
meteorological records and climatic factors in relation to, Fla. 168.
native, market outlets and local uses for, N.Mex. 860.
new, for Malheur County, Oreg. 35.
new, for old, 26.
new varieties, Nebr. 383.

Crops—Continued.

- nutrition, control by foliar diagnosis, Pa. 190.
 of muck and sandy soil, production, Ind. 645.
 preparing seedbeds for, Wyo. 503.
 productive farm, treatise, 501.
 rotations, soil-conserving and soil-improving, for the Palouse, 040.
 sand culture, Conn.[New Haven] 512.
 soil-building, development and testing, Calif. 199.
 variously treated. phosphorus in, Ky. 501.
 winter hardiness, tests, Alaska, 362.
 yields, measuring on community scale, 638.
 yields, relation to available phosphorus, 483.
 yields, relation to fertilizer placement, Miss. 774.
- Crotalaria**—
 culture experiments, Ga.Coastal Plain 363.
 feeding value, Fla. 254.
 rotations under Everglades conditions, Fla. 200.
 seed, germination studies, Ala. 33.
 value in fertilizer tests, Miss. 774.
 variety tests, Ga.Coastal Plain 363, La. 639, S.C. 36, Tex. 37.
- Crown gall, relations between host and parasite in, 380.
- Crows and white-necked ravens, food of, comparison, 804.
- Crows, damage to fall grain crops, U.S.D.A. 668.
- Crucifer**—
 black ring, a virus disease, 47. 54.
 club root, West.Wash. 379.
 sawfly, life history, 82.
 seed treatment for flea beetle control, 400.
- Crucifers, hybridization, Tex. 41.
- Cryolite sprays, magnesium oxide as corrective, 238.
- Cryptoccephalus incertus*, notes, Mass. 540.
- Cryptococcus* sp., notes, 111.
- Cryptorhynchus lapathi*, see Poplar and Willow borer.
- Cryptosporopsis* spp., notes, 491.
- Cryptotermes brevis*, notes, P.R.Col. 244, 541.
- Ctenodermus*, taxonomic study of genus, 223.
- Cucumber**—
 beetle, spotted, notes, Tex. 87.
 beetle, striped, and wilt disease, 807.
 beetle, striped, on cucumbers and melons, Mass. 540.
 beetles, Ind. 672.
 beetles, control by rotenones, Wis. 541.
 downy mildew, control, La. 656, S.C. 50.
 downy mildew resistant varieties, new, P.R.Col. 527.
 downy mildew resistant variety, Fla. 221.
 insects, control, 674.

Cucumber—Continued.

- Phytophthora capsici* rot of, 47.
 pickle industry, needs of, Miss. 787.
 scab resistance, development, Me. 40.
- Cucumbers**—
 bordeaux injury to, 654.
 breeding for scab resistance, 798.
 effect of copper sprays, Conn.[New Haven] 526.
 fertilizer and lime requirements, La. 645.
 fertilizer requirements, P.R.Col. 512.
 induced parthenocarpy of, 492, 513.
 sprays for, Mass. 526.
 storage, factors affecting, Tex. 41, 141.
 varieties and fertilization, S.C. 41.
- Cucurbit scab or pox, Del. 221.
- Cucurbita pepo ovifera* as prototype of cultivated forms, 496.
- Cucurbits**—
 diseases, U.S.D.A. 794.
 fruit size in, relation to cell size, 488.
 mosaic-resistant, breeding, N.Y.State 211.
 sprayed with bordeaux mixture, dwarfing, 663.
- Culex tarsalis* in Owens Valley, California, 681.
- Culicidae, ovulation in, role of blood, 810.
- Cultivator, motor-driven rotary, of foreign manufacture, Iowa 115.
- Culture media containing milk, productivity for coliform group, 414.

- Cuproicide toxicity, effect of aging, Tex. 51.
- Cuprous oxides, fungicidal value, relation to particle size and color, 53.
- Curly top in Pacific Northwest, U.S.D.A. 220.
- Currant**—
 anthracnose, notes, 232.
 bud mite, control, 69.
 juice and jelly, Mass. 591.
 mosaic, 61.
- Currants, selection and propagation, Alaska 374.
- Curculia lunata*, notes, U.S.D.A. 48.
- Cuscuta arvensis* outbreak on black locust seedlings, 802.
- Custom, old southern, of use of hot biscuits and molasses, vindication of value, Miss. 367.
- Cutworm**—
 Atlantic, notes, Mass. 540.
 black, on corn in Java, 393.
 dark-sided, notes, Conn.[New Haven] 540.
 spotted, notes, Conn.[New Haven] 540.
- Cutworms**—
 climbing, control, 807.
 notes, Ind. 671.
 use of baits for, Wis. 541.
- Cycus revoluta*, structure and growth of shoot apex, 764.

Cyclamen mite—

- control, 807, Calif. 238.
- on gerbera, control, U.S.D.A. 401.
- on strawberry, control, Idaho 657.
- Oreg. 71.

Cylas formicarius, see Sweetpotato weevil.

Cyllene robiniae, see Locust borer.

Cyonin, suggested use of term, 30.

Cypress, pecky, cause, 64.

Cytolichus nudus in fowls in India, 837.

Cytological technic, permanent root tip, improvements in, 763.

Cytopenia, nutritional, in monkeys, 439.

Cytospora rot of sugarcane, 228.

Dacinae, new genera, 350.

Dactylella ellipsospora, effect on root knot nematode injury, 660.

Dacus brevistylus, life history and habits, 810.

Dacus spp. in Java, 399.

Dahlia roots in storage, conditions affecting, [N.Y.] Cornell 45.

Dairy—

breeds, relative efficiency in converting vitamin D in feed to milk, S.Dak. 263.

cattle and dairy cows, see Cattle and Cows.

competition, Wisconsin, live weight and milk-energy yield in cows, 265

farms, economic data, R.I. 854.

farms, income on, Mass. 555.

farms, receipts, costs, and profits, Miss. 854.

feeding, usefulness of urea and other nitrogen compounds, 703.

herd breeding records, analyses, 771.

herd performance, La. 700.

husbandry, American, 732.

management, profitable, Mich. 435.

plants, changes in percentage receipts, Wis. 123.

plants, proportion of total milk handled by, Wis. 123.

population of Colombia, 464.

products—

examination, standard methods for, handbook, 704.

gas production in, methods of measuring, 567.

judging, 702.

new, development, Mass. 562.

of Iowa, standardization, Iowa 96.

organisms important in, classification, Iowa 96.

plate counts, effect of new standard agar, 701.

production and consumption by farm families, S.C. 141.

production and manufacture, Nebr. 404.

production of 2,3-butylene glycol in, Iowa 96.

research, relation to regulatory legislation, 701.

sires, see Bulls and Sires.

Dairy—Continued.

utensils, washing and sterilizing on the farm, instantaneous steam generator for, 429.

water heaters, electric, Ind. 720.

Dairying, see Creameries, Butter, Milk, etc.

Dalbergia also ins. ctns. guide for forest officers, 71.

Dallis grass—

fertilizer tests, Fla. 200.

stands, effect of time of planting, Ala. 83.

Damping-off—

control by seed treatment, Tex. 51.

of early forcing vegetables, soil surface treatments in hotbeds, Mass. 326.

of seedlings, control, Tex. 51.

organisms, growth in pure culture, effect of fungicidal chemicals, Tex. 51.

Dandelion, new form in Missouri, 621.

Danforth, S. T., biographical sketch, P.R.C. 669.

Dasyneura lini—

chalcid parasite of, 811.

new chalcidoid parasites of, 823.

of linseed in India, new cecidomyid pest, 810.

Datana integerrima, see Walnut caterpillar.

Date—

palm decline disease, 232, Calif. 220

palms, water use by, 651.

pollen, cold storage, 652.

Dates—

drying, mud brick oven for, 809.

growing in United States, U.S.D.A. 44.

moisture determination in, 613.

size of fruit as affected by soil moisture, 652.

soft varieties, maturation and storage studies, 652.

spoilage, control, 232, Calif. 220

varieties and propagation, Tex. 41

Datura stramonium, new or modified chlorophylls of, 180.

Davainea—

proglottina infection of fowls, effect on weights of growing chickens, 112.

tetracensis, parasite of ruffed grouse, Mich. 805.

Deathwatch beetle, notes, 394.

Debaryomyces—

glabrous, heat resistance studies, 764.

yeasts from fresh sausage, 303.

Deciduomata, survival during lactation in rat, 359.

Deer—

ectoparasites in British Columbia, 672.

fall and winter food habits in Minnesota, U.S.D.A. 669.

protecting orchard trees from, U.S.D.A. 668.

white-tailed, pine in diet, 219.

Deficiency diseases, see Diet deficiency and specific diseases.

Delaware Station, notes, 370, 462.

- Delaware Station, report, 319.
 Delaware University, notes, 320, 462.
Delphacodes striatellus on rice in Japan, 545.
 Delphinium—
 diseases, 62.
 powdery mildew, 62.
 propagation, Mass. 512.
 southwestern, effect of genesis of earth forms, 485.
Deltocephalus dorsalis—
 on rice in Japan, 545.
 vector of dwarf disease of rice, 75.
 Dentin, rate of apposition, effect of vitamin A deficiency, 145.
 Department of Agriculture, see United States Department of Agriculture.
 Depression, effect on rural life, 133.
 Dermacentor—
 albipictus, see Tick, winter.
 and *Otocentor* genera in United States, 687.
 andersoni, filter-passing infectious agent isolated from, 276.
 andersoni, vector of equine encephalomyelitis, 845.
 occidentalis, see Tick, Pacific coast spp., acquired immunity to, 276.
 variabilis, see Dog tick, American.
 Dermatitis in rats, 600.
 Dermatitis, filarial, of sheep, 421.
Dermeestes lardarius, see Larder beetle.
 Dermestid larvae, injurious in dwelling houses, [N.Y.] Cornell 68.
 Derrengadira in Venezuela, 539.
 Derris—
 as insecticide, history, 244, U.S.D.A. 242.
 literature on, U.S.D.A. 242.
 of high rotenone content, 539.
 spp., list of common names used for, U.S.D.A. 806.
 toxicity to whitefly larvae and purple scale, Ala. 65.
 Desert subsoil temperatures, 337.
 Deserts, frozen, nutritional and health values, 865.
 Deuterium, use in biological work, 304.
 Devil's shoestring as insecticide, Tex. 66.
 Dew, measuring, volumetric apparatus for, 476.
 Dewberries, breeding, Tex. 41.
 Dewberry rosette due to *Cercospora rubi*, La. 656.
Dezia rustica, parasite of cockchafer, 684.
 Dextrose—
 in commercial ice cream manufacture, Ill. 415.
 in food industries and its health status, 596.
 properties, Iowa 4.
 utilization, effect of food laws, Iowa 292.
 Diabetes—
 modern treatment, 601.
 vitamin C status in, 151.
Diabrotica—
 duodecimpunctata, see Cucumber beetle, spotted, and Corn rootworm, southern.
 vittata, see Cucumber beetle, striped.
Dialeurodes—
 citri, see Whitefly, citrus.
 dissimilis, sexual dimorphism and post-embryonic growth in, 395.
 Diamondback moth—
 natural and biological control in England, 247.
 notes, Tex. 67.
Diaprepes spp., notes, 401.
 Diarrhea, bacillary white, see Pullorum disease.
Diatraea grandiosella, see Corn borer, southwestern.
Diatraea saccharalis, see Sugarcane borer.
Dichocrocis punctiferalis on papaw, 393.
Dichondra carolinensis *Alternaria* blight, Fla. 222.
 Dicotyledons, flower buds and phylogeny of, 347.
 Dictionary of plant names, 19.
 Dictyocaulosis—
 of horses, pathologic anatomy and pathogenesis, 834.
 of horses, treatment, 835.
 of sheep, treatment, 835.
Dictyostellum discoideum, growth and development, effect of culture conditions, 24.
 Diet—see also Food and Nutrition.
 deficiency diseases—see also specific diseases.
 in Kashmir, 748.
 family, planning around need of growing girls for iron-rich food, Miss. 867.
 farm family, in Coastal Plains of South Carolina, S.C. 866.
Diethylstilboestrol and oestrogenic hormones, difference of effect, 199.
 Diets—
 of different protein levels, growth, activity, and composition of rats on, 556.
 of families of wage earners and clerical workers in cities, U.S.D.A. 142.
 of varying protein levels, heat increments of, 556.
 summer, of poor in Washington, 308.
Digitaria, germination, temperature relations, 181.
 Dill leaf and stem blight, Tex. 52.
 Dill, photoperiodic responses, 765.
Dinapate scirpithi, economic pest in lower California, 822.
 Dinitro-*o*-cyclohexylphenol, studies, 675, 676.
Diorchis skrjabini n.sp., parasite of *Anas circa*, 838.
 Diphtheria in calves, Wyo. 569.
Diphyllbothrium sp. from herring gull, life cycle, 105.
Diplocarpon—
 earhana, notes, 801.
 rosae spore germination, effect of fungicides, Tex. 51.

- Diplodia**—
trumentii and forms resembling, comparison, Fla. 221.
seae dry rot of corn, Iowa 49.
Diplopoda, notes, 809.
Diploscapter coronatus on ginger rhizomes, 535.
Dipping fluids containing arsenic and sulfur, toxicity, 570.
Diptera, muscoid, new genera and species, 820.
Dirofilaria—
immitis in dogs, ineffectiveness of sulfanilamide treatment, 577.
immitis, transmission in Massachusetts, 718.
scapiceps, development of microfilaria in mosquitoes of Minnesota, 106.
Discosporiella phaeosora, notes, 491.
Dispharynx—
human, mechanical carriers, 72.
of animals, see *Animal diseases and specific diseases*.
of plants, see *Plant diseases and specific host plants*.
Disinfectants, farm, efficiency, Wash. 274.
Dispharynx—
pipilonis n.sp., description, 805.
spiralis in bird hosts, biological and morphological relations, 835.
spiralis, parasite of ruffed grouse, Mich. 805.
Distemper—
canine, 111.
canine, and lymphocytic choriomeningitis viruses, simultaneous occurrence, 846.
canine, and vitamin A of shark-liver oil, 423.
inclusions, comparative study, 284.
natural, in gray foxes, 834.
of silver foxes, 424.
virus, modification by animal passage, 834.
Distillers' byproducts, nutritive value, 89.
Dithizone solutions, stability, 4.
Diversinervus sp., promising parasite of black scale, 237.
Dodder—
and its insects, 812.
control on annual lespedeza, 644.
on tomato in Texas, U.S.D.A. 378.
Dog food, canned—
Alabama standard, 694.
nutritive value, 408.
preparation of samples for chemical analysis, Ala. 8.
Dog tick—
American—
acquired immunity to, 572.
control, U.S.D.A. 242.
in United States, 687.
brown, resistance of larvae and behavior on human skin, 840.
Dogs—
and rats, comparative nutritive requirements, Ala. 84.
dry rations for, comparison, Ala. 84.
Dogs—Continued.
effects of lead and arsenic in diet, 106.
hookworms in, 284.
immunized against *Ancylostoma caninum*, protective power of serum from, 104.
nicotinic acid requirements, 747.
salmon poisoning, sulfanilamide as treatment, 424.
Dolomite of varying particle size, citrate solubility, 327.
Dorythenes forficatus in Morocco, 400.
Dothichloe limitata n.sp., identity and parasitism, 657.
Dothiorella nima, notes, 64.
Doughnuts, cooking at high altitudes, Wyo. 591.
Doves—
mourning, food habits, U.S.D.A. 669.
North American, hippoboscids flies from, 685.
Downy mildew—
notes, U.S.D.A. 655.
severe occurrence in south Georgia, U.S.D.A. 794.
Drainage—
channels and terrace outlets, U.S.D.A. 851.
problems, Calif. 169.
tile, experiments, Ind. 851.
Drepanosiphum orephonensis n.sp. on maple leaves, 817.
Drepanothrips reuteri, notes, Calif. 245.
Dresses—
silk street, consumers' choices in purchase, 885.
silk, studies, 886.
Dried fruit beetle, populations in soil, equipment and methods for estimating, U.S.D.A. 241.
Drier, portable field, 423.
Drinking fountains, automatic, in experimental hog lots, use of electric heat in, Ind. 720.
Drought—
conditions, offset by planting windbreak trees to retain drifting snow, 522.
relation to farm population movement, N.Dak. 604.
Droughts of 1930, 1931, and 1936 in Corn Belt and associated areas, 476.
Dry farming, use of press-type furrow drill in, Idaho 719.
Drying, artificial, of forage crops, use of bituminous coal in, 429.
Ducks—
cytological studies of testes and ovaries, 493.
diving, of North America, food habits, U.S.D.A. 538.
fatal disease, cause, 847.
game, food in United States and Canada, U.S.D.A. 538.
mortality due to *Salmonella typhimurium* infection, 847.
of the world, 804.

Ducks—Continued.

wild, seasonal abundance of parasites, 236.

Dung beetles, notes, P.R. 250.

Dung rolling beetle, host of *Sarcophaga albedo*, 237.

Duststorms and dust walls, 476.

Dyes—

aniline, bactericidal efficiency, 708.

azo, fastness to light and washing, effect of position isomerism in, Ohio 460.

fastness on miscellaneous dress fabrics, 886.

Dysentery in newborn calves, acute fatal colon group bacteria as cause, 842.

Ear tick in India, 836.

Earlas fabia, notes, 542.

Earth, rammed, for farm building walls, S.Dak. 287.

Earwig—

destructive to greenhouse radishes, 807.

European, as food of little owl, 67.

European, control, U.S.D.A. 805.

Easter lily, bulb mite attacking, 254.

Eberhardia sp., notes, 69.

Eberthella typhi, efficiency of aniline dyes against, 708.

Echinococci—

larval, resistance against physical and chemical agents, 835.

maintenance in United States, 841.

Echinoparyphum syrdariense n.sp., new trematode of fowl, 835.

Ecology in agriculture, 486.

Economic policy of New Zealand, recent changes in, 854.

Ensisotomorphia taskhiri n.g. and n.sp., description, 823.

Edestin, growth-promoting power, effect of heat, Wis. 87.

Education—

agricultural, see Agricultural education.
improvement in rural Indiana, 298.
public and private, in Tennessee, 298.

Egg—

albumin, see Albumin, egg.

auctions, selected references, U.S.D.A. 858.

cases in storage, mold on, 898.

cooler, evaporation-type, value, Okla. 85.
production—see also Hens, laying.

breeding for, significance of body weight in, Mass. 827.

effect of protein level, Okla. 85.

effect of sulfur supplements in diet, Wis. 554.

high, breeding for, Hawaii, 688.

in New Jersey, feed cost, N.J. 561.

meat scraps and milk combinations.
different levels, Iowa 84.

mode of inheritance of factors affecting, Calif. 254.

protein supplements, comparison, 261.

use of electric light in stimulating, Wash. 287.

Egg—Continued.

proteins, biological value in human subjects, 305.

proteins, biological value in rats, 305.
quality, effect of cottonseed meal in ration, Okla. 85.

quality, effect of poor sanitation, Okla. 85.

solids as constituent of ice creams, Mass. 562.

yolk, carotene in, effect of levels of carotene intake, Idaho 688.

yolk of hens, alternate white and yellow layers of, 697.

yolk, petroleum-phasic carotenoids of, 84.

Eggplant—

bacterial wilt resistant varieties, development, P.R.Col. 527.

lacebug, control, Okla. 68.

yellow, control, Tex. 52.

Eggplants—

damping-off, seed and soil treatments for, 654.

growth and yield, relation to soil reaction, Fla. 210.

response to soil fumigation with chloropicrin, R.I. 795.

Eggs—

biological efficiency of protein fractions, Iowa 84.

buying and retailing on grade basis, Ind. 721.

characters, breed variations in, 827.

composition, effect of diet and storage, 95.

deterioration due to ingestion of malvaceous materials, 830.

developing, follicular hormone in yolk, relation to blood calcium, [N.Y.] Cornell 27.

hatchability, Wis. 554.

hatchability and subsequent growth of chicks, effect of single cereal grains, 828.

hatchability, effect of cottonseed meal and oil in laying rations, S.C. 86.

hatchability, relation to viscosity index, Iowa 84.

hatching and incubator, proper handling on farm, N.J. 562.

high quality, for Illinois markets, Ill. 697.

incubating, use as differential medium, 840.

infertile, early detection, [N.Y.] Cornell 85.

infertile, quality, effect of high temperatures for short periods, 411.

infertile, value in chick rations, Wis. 554.

interior quality—

effect of green feed, 411.

effect of heredity and environment, Wash. 255.

inheritance of differences between lines in, [N.Y.] Cornell 27.

Eggs—Continued.

- oil-treating, effect on keeping quality, 698.
- prices, index number, N.Dak. 131.
- processed, oil content of shells, 613.
- quality and size, effect of rations and management, Iowa 84
- quality, effect of conditions during shipping, West.Wash. 404.
- quality, effect of storage conditions, Wash. 253.
- quality, factors affecting, Pa. 86.
- storage, methods and equipment for, Nebr. 720.
- unbroken, measurement of freshness, 698.
- vitamin A in, determination, 263.
- vitamin A in, effect of administration of large amounts of vitamin A, 453.
- Eggshell quality, effects of manganese. Ark. 411.

Eimeria—

- bukidnonensis* in New York State cattle, 105.
- hagani* n.sp. from chicken, 112.
- n.spp., description, Oreg. 285.
- spp., avian hosts, 709.
- tencella*, viability of oocysts, 112.

Elaeophora schneideri larvae in skin of affected sheep, 421.

Electric—

- dairy water heaters, Ind. 720.
- milk refrigeration on farms, Pa. 287.
- mixers and beaters for household use, Ind. 749.
- pig brooders. Ind. 720.
- plants, wind, Ind. 720.

Electrical resources and development in Tennessee, 584.

Electricity—

- facts for farmers concerning, Wash. 119.
- use in agriculture, Wash. 287.
- use in brooding chicks, Ind. 720.
- use on Nebraska farms, Nebr. 720.

Electrokinetics, studies, Minn. 469.

Elements—

- minor, and major soil problems, 17.
- minor, in soil fertility and plant nutrition, Oreg. 17.
- minor, necessity in economy of plants and animals, 186.
- trace, physiological importance in organisms, 310.

Elevators—

- cooperative grain, accounting procedure for, 725.
- cooperative grain, operations in Kansas and Oklahoma, 725.
- farmer owned, of Ohio, financial operations, 443, 725.
- farmers', grain handling methods and merchandising, Iowa 121.

Elm—

- aphid, woolly, notes, Fla. 238.
- bark beetle, native—
 - infestation of logs, effect of sunlight and location, 252.

Elm—Continued.

- bark beetle, native—continued.
 - larval development, 252.
 - life history and control, Conn.[New Haven] 253.
 - notes, Mass. 540.
- bark beetle, smaller European—
 - elm twig crotch injuries from, 696
 - infestation of logs, effect of sunlight and location, 252.
 - notes, Mass. 540.
- borer, relation to *Ceratostomella ulmi* infection of American elm, 390.
- Chinese, for semiarid conditions of western Kansas, 486.
- disease, Dutch—
 - aid in eradication, 389.
 - bark beetles concerned in, Mass. 341.
 - control, Conn.[New Haven] 526.
 - in United States, U.S.D.A. 219
 - insect vectors and control, [N.Y.] Cornell 40.
 - studies, [N.Y.] Cornell 49.
- diseases, Conn.[New Haven] 526.
- leaf beetle, notes, 238, U.S.D.A. 821.
- logs, beetle infestations, effect of sunlight and of location of logs, 252.
- seeds, storage, 217.
- specimens, *Ceratostomella ulmi* on, tabulation, U.S.D.A. 525.

Elm—

- Cephalosporium* dieback of, 64.
- resistant to *Graphium ulmi*, 666.

Elinoe—

- faucetti*, causal fungus, history, 47.
- spp. in United States, new records, U.S.D.A. 220.

Emblemasoma n.spp., notes, 820.

Embryo life, maintenance in ovariectomized rabbits, 199.

Embryogeny, new type in conifers, 347.

Embryonic growth rates, avian, comparison, Iowa 84.

Emmer seed disinfection, N.Dak. 225.

Empoasca—

- devastans*, notes, 811.
- fabae*, see Potato leafhopper.
- sp. on cotton in Java, 542.

Empusa—

- grylls* in Oklahoma, 238.
- musae* infections of housefly, relation to moisture, 683.

Encephalitis—

- equine, in man, 418.
- moose, description, 844.
- Encephalitosoon* sp., notes, 111.
- Encephalomalacia—
 - nutritional, of chicks, and related disorders, [Conn.] Storrs 696.
 - of chicks, effect of vitamin K excess, 696.

Encephalomyelitis—

- equine—
 - control, 576.
 - eastern type in guinea pig, 423, 575.
 - in a brood mare, Ky. 569.
 - in monkeys, 576.

Encephalomyelitis—Continued. equine—continued.

in mounted military police troop, 837.

in Venezuela, causative agent, 283, 716.

midwinter case in Florida, 284.

New England outbreak, 716.

notes, Wyo. 569.

present status and control, 717.

preventive measures, N.Dak. 111.

recovery from, 716.

relation to mosquitoes, 807.

secondary disease following, 717.

susceptibility of squirrels to virus, and ticks as vectors, 845.

symptoms, treatment, and prevention, 423.

tick as vector, 845.

transmission and possible vectors in human being, 717.

virus from ring-necked pheasant, 423.

virus, Moscow 2 strain, 283.

virus, transmission by *Aedes* spp., N.Dak. 548.

western strain in Kentucky, 111.

western type, recovery of virus, 576.

in infants, verification by transmission to animals, 419.

Endocrine—

glands, effect on reproduction and lactation cycles, 359.

glands, weights, effect of avitaminoses, 144.

system, nature, interrelations, and mode of action of hormones, 497.

Endocrinology, importance to animal husbandman, 497.

Endometrium sensitivity during lactation in rat, duration, 195.

Endothia parasitica, new chestnut resistant to, development, 536.

Engineering—

agricultural, in North America and Germany, 732.

Agricultural, International Congress of, notes, 160.

Enteritis, catarrhal, of young turkeys, 114.

Enterobiosis, treatment by carbon tetrachloride, 836.

Enterohepatitis, infectious, see Blackhead.

Enterotoxemia—

among sheep in Madras, 836.

infectious, of young lambs, Tex. 104.

of lambs, 843.

of sheep, Calif. 273.

Entoma, a directory of insect pest control, 814.

Entomological conditions in Florida, 871.

Entomology—see also Insects.

applied, development in Queensland, 542.

applied, problems in Pernambuco, Brazil, 240.

medical, treatise, 813.

research, fifty years of, 803.

Entomophthora sp. from white apple leaf-hopper, 539.

Enzyme formation, adaptive, physiological youth as important factor, 187.

Eumenacanthus stamineus, see Chicken body louse.

Ephedra sinica as drug plant with tendency to prevent soil erosion, S.Dak. 201.

Ephemeral fever of cattle, 392.

Ephestia—

control on dates, constant temperature hot air sterilizer for, 809.

elutella, see Tobacco moth.

kuchniella, see Flour moth, Mediterranean.

Epibootania nonvitta, morphology and biology, 824.

Epicauta ruficeps on corn in Java, 393.

Epilachna—

beetles, high fecundity of, 811.

indica, alimentary canal and activities of mid-gut epithelium, 809.

ravivestris, see Bean beetle, Mexican.

Epimegastigmus brevipalpus, morphology and biology, 823.

Epinasty of potato leaves, chemical vapors inducing, tests, 348.

Epitrix—

cucumeris, see Potato flea beetle.

parvula, see Tobacco flea beetle.

Equine breeding hygiene, 422.

Eriococcus coriaceus, notes, 72.

Eriophyes—

lycopersici n.sp., description, 824.

pyri, see Pear leaf blister mite.

ribis, see Currant bud mite.

Eriophyid studies, additional forms, 254, 824.

Eriosoma lanigerum, see Apple aphid, woolly.

Erosion, see Soil erosion.

Erwinia amylovora—

strains, [N.Y.]Cornell 49.

susceptibility of plants to factors in, Calif. 380.

Erysipelothrix rhusiopathiae associated with fatal duck disease, 847.

Erysiphe polygona, notes, 62.

Erythmelus psallidis n.sp., parasite of cotton flea hopper, 545.

Erythronoea pallidifrons, biology and control, 245.

Erythronium albidum, development of megagametophyte in, 765.

Escherichia coli—see also *Bacterium coli*, *communis* in pullets, 113.

efficiency of aniline dyes against, 708.

Ethyl alcohol fermentation, production of caproic and butyric acids by, 167.

Ethylene—

dichloride for peach borer control, 239.

in plant tissue, determination, 215.

production, use, and reactions in plants, 186.

Eublemma amabilis on lac, parasite of, 811.

Eucalyptus, insect pests, 72.

Euchlaena, Tripsacum, and corn, genetic and cytological relations, Tex. 37.

Euderus—

gossypii, parasite of cotton borer beetle, 401.

pempheriphila, n.sp., description, 401.

Eulimneria albae, technic and equipment for handling to prolong hibernation, U.S.D.A. 242.

Eumacronychia genus, key and descriptions of new species, 684.

Eupelmus terminatae n.sp., description, 810.

Euphoranthe dyserci n.sp., description, 251.

Euplectrus agaristae, life history, 82.

Eurydinota loidicorpus, parasite of cherry casebearer, 680.

Eurythrips robustisetis, new from Florida, 678.

Eurytoma—

fellis, parasite of, 823.

samsonovi, pest of fruits in India, biology, 823.

Eurytremia pancreaticum, notes, 836.

Euscepes batatae, see Sweetpotato weevil, West Indian.

Euschistus variolarius, notes, Conn.[New Haven] 540.

Eustictus n.sp., description, 816.

Eutermes callosus, gaseous environment, 72.

Eutettia tenellus, see Beet leafhopper.

Euzoa—

interfectionis on corn in Java, 393.

messoria, see Cutworm, dark-sided.

segetum on corn in Java, 393.

Euzophora puniceella, notes, 547.

Evaporation—

from land surfaces of earth, relation to temperature and precipitation, 168.

rate, relation to other meteorological factors, 11.

studies, Ohio 333.

Ewes—see also Sheep.

blood, sugar and ketone content, 258.

diseases on New York market during winter, U.S.D.A. 525.

diseases, studies, N.Y. State 222.

growers, experimental findings of interest to, 213.

growing, development of, landmarks in 751.

insects, Ind. 672.

insects, biological control, 807.

insects, control, 813.

insects in South India, 70, 811.

juices, Calif. 165.

little leaf on stone fruits, 534.

moth, oriental—

fumigation of dormant nursery stock for, U.S.D.A. 242.

parasites, Ky. 540.

parasites, introduction into peach orchards, Mass. 540.

parasitism and control, 806.

status in Indiana, 813.

studies, 393, 813, Conn. [New Haven] 540, Del. 238, S.C. 68.

use of baits for, 819.

pests, 392.

pests and parasites, 672.

pests of North-West Frontier Province of India, 70.

products, phosphorus determination in, 329.

products, utilization, Wash. 165.

set in Washington orchards, factors affecting, Wash. 211.

spotting bug on papaw, 393.

tree bacterial canker, Calif. 220.

tree cuttings, response to treatment with synthetic root-forming substances, 515.

Fruit—Continued.

tree leaf roller, control, Mo. 396.

tree stocks, diseases, identification and control, Iowa 48.

trees—

failure to bear, cause, U.S.D.A. 44.
growing to withstand drought, N.Dak. 791.

growth and activity of roots under varying conditions, [N.Y.] Cornell 43.

improvement by grafting and budding, Miss. 757.

in Wenatchee-Okanogan District, Wash. 587.

irrigation, Calif. 210.

new winter washes for, 70.

nutrition situation, 213.

pruning, Kans. 515.

response to minor elements, 220.

rootstocks, identification and culture, 790.

spray injury to, nature, Wash. 211.
summer training, Miss. 787.

studies, Nebr. 378.

winter injury, causes, Wash. 211.
wound dressings for, [N.Y.] Cornell 43.

Fruitflies—

and their parasites in Fiji, 69.

development, effect of low temperatures, 549.

Fijian, bionomics, 79.

heat sterilization of Formosan fruits for, 550.

Natal, olfactory attractants for male, 79.

new genera and new species from Africa, 549.

new species, descriptions, 79.

noxious, in Java, biology and control, 399.

trypanid, new genera and new species of Australia, 550.

Fruitfly—

Mediterranean—

pest of citrus in South Africa, 815.
reaction of orange fruit to autumn attack, 685.

structure and operation of reproductive organs, 809.

Natal, pest of citrus in South Africa, 815.

pests, bionomics and control, 811.

Fruits—see also Orchards, Apples, Peaches, etc.

auxin distribution and significance in development, 348.

citrus, see Citrus.

containers for U.S.D.A. 513.

cooperative marketing, 293.

dried, insects affecting, U.S.D.A. 242.

dried, sulfuring difficulties, Calif. 165.

dwarf, U.S.D.A. 44.

fresh, precooling in refrigerator cars, Ind. 720.

gas storage, Calif. 210.

Fruits—Continued.

- growing in New York, relation to soils, [N.Y.]Cornell 43.
- handling and storage, Wash. 211.
- high in mineral and vitamin content, selection of genetic strains, Me. 140.
- home preparation for freezer-locker, Tenn. 303.
- household storage, 593.
- marketing, Ind. 645.
- marketing, on farmers' markets in New York Metropolitan District, [N.Y.] Cornell 129.
- minerals in, Mass. 460.
- native, market outlets and local uses for, N.Mex. 860.
- phosphorus determination in, 329.
- physiological dropping, factors affecting, Del. 210.
- plant pigments in, Calif. 165.
- pollen longevity studies, 646.
- pollination, Calif. 210.
- preservation by freezing in Pacific Northwest, U.S.D.A. 738.
- preservation in cold storage lockers, N. Dak. 142.
- production, fundamentals, treatise, 646.
- red color formation during and after harvest, [N.Y.]Cornell 43.
- small, breeding, Me. 40.
- small, culture on State farms, Miss. 787.
- small, insect pests, 239.
- small, varieties, N.Mex. 787, Okla. 40, S.C. 41.
- small, variety tests, Alaska 374, La. 645, Me. 40, Wyo. 513.
- spray practice, effect of recent increase in government lead tolerance, 813.
- spraying directions, Ill. 375.
- spraying program, Ohio 515.
- statistics, Calif. 132.
- stone and pome, developmental morphology, N.Y.State 213.
- stone, diseases in New York State in 1938, 231.
- stone, little-known and imperfectly understood diseases, cause, [N.Y.]Cornell 49.
- stone, species causing brown rot of, 60.
- stone, virus diseases in Bulgaria, 61.
- stored, volatile products liberated from, 330.
- surplus, other uses for, Calif. 165.
- time of blooming, N.Mex. 787.
- varieties, Fla. 210, Okla. 40, Wash. 211, West.Wash. 374.
- varieties, tree characters, Mass. 512.
- variety tests, Ga.Coastal Plain 374, Ky. 512, Mass. 512.
- vitamin C in, Fla. 300.

Fruitworm—

- notes, Wash. 239.
- oriental, and parasites, 813, Ind. 672.
- Pactus alides*, paraffin embedded, dioxan dehydration for, 763.

Fumigants, greenhouse, Mass. 540.

Fungi—

- associated with seedling diseases and boll rots of cotton, 654.
 - edible, animals associated with, 670.
 - entomogenous, among red locusts, 678.
 - entomogenous, notes, 72.
 - fruit-rotting, synergism in, 232.
 - genetic changes in, chemical induction, 620.
 - growth in synthetic nutrient solutions, 491.
 - heart-rotting, two distinct, characters and distribution, 234.
 - heavy metal nutrition of, 352.
 - Imperfecti from Pacific Northwest, 52.
 - interaction between, 523.
 - new to Kansas, 526.
 - noteworthy of Florida and Georgia, U.S.D.A. 378.
 - nutrition, effect of inoculum on colony growth, 523.
 - of Duke Forest and host index, 389.
 - of Venezuela, P.R.Col. 183.
 - soil-borne, and control of root disease, 224.
 - thermophilic, in soils and in composts, 176.
- Fungicides—*see also* Sprays and specific kinds.
- copper, *see* Copper.
 - dust, development and testing for cereal seed treatment, Iowa 48.
 - laboratory toxicity tests, theoretical principles, 656.
 - toxicity, Tex. 51.
 - toxicity, effect of aging, Tex. 51.

Fungus—

- cultures, central bureau for in Baarn, Netherlands 621.
 - parasites, nutrition, osmotic and permeability relations, 796.
 - spores, germination, effect of vitamins, 766.
- Fur-bearing animals, diseases and parasites, treatment, 112.
- Fur farming—
- in Oregon, problems, Oreg. 68.
 - sanitation in, 804.
- Fur laws, abstract, U.S.D.A. 668.
- Furniture, household, rubberized fumigating bags for, 807.

Fusarium—

- batatas*, control, Del. 221.
- diseases of plants, N.Y.State 222.
- leaf blotch of tobacco, Conn.[New Haven] 530.
- Int, growth and metabolism, Pa. 52.
- nitreum wilt of watermelon, control, Fla. 221.
- spp., length of conidia, effect of light, 351.
- spp. on coffee roots, P.R.Col. 527.
- vasinfectum* on cotton, studies, 654.
- vasinfectum* wilt of cotton, S.C. 50.
- wilt of China aster, Ind 656.

Fuvarium—Continued.

- wilt of cotton, relation to soil moisture, 55.
- wilt of potato, Nehr. 656.
- wilt of tobacco, Ga.Coastal Plain 378.
- wilt of tomato, immunity to, 636.
- wilt resistant watermelons, 231.
- yellow of gladiolus, 233.
- yellow of tobacco, Ky. 526.

Fusicladium—

- dendriticum*, see Apple scab.
- robiniae*, in forest tree nurseries, U.S.D.A. 48.

Galerucella xanthomelaena, see Elm leaf beetle.

- Gall inhabitants, hymenopterous species, 823.
- Gall midge, new, on rhododendron, description, 682.

- Gall mite, injurious to tomato, 824.

Galleria mellonella, see Wax moth.

- Galls, pseudogalls, aphids, and auxins, 180.

Game—

- big, inventory of United States, U.S.D.A. 668.
- law enforcement, Federal, personnel in, U.S.D.A. 669.
- management and research units in land-grant colleges, 67.

Gapeworms—

- domestic fowls as carriers, 104.
- flies as intermediate hosts, 682.
- in fowls, 837.
- in pheasants, use of iodine for, 425, R.I. 834.
- removal from chickens by barium antimonyl tartrate, 105, 112.

Gardenia—

- bacterial leaf spot, new menace to, 63.
- canker and gall disease, West.Wash. 379.
- Phoma* stem canker, Calif. 221.

Gardenias, culture, factors in, Mass. 512.

- Gardens, fallowing and irrigation, comparison, Wyo. 513.

Gargaphia solani, see Eggplant lacebug.

Garlic diseases, Tex. 51.

Garlic drying, Tex. 116.

- Garlic, wild, seasonal activity of bulbs related to control, Ala. 33.

Gas, fuel, production from farm wastes, 167.

Gas thermoregulator, flexible, Minn. 471.

- Gases, thermal conductivity, determination, 472.

Gastric juice—

- effect of vitamin C saturation, 744.
- vitamin C in, 744.

Gastromyzus mustosus, notes, 244.

- Gastritis, traumatic, induced cases in dairy cattle, 279.

Geese of the world, 804.

Geese, Pilgrim, sexual dimorphism in, 358.

Geigerin, constitution, 274.

Gelatin—

- effect of aging treatments, Mass. 562.
- effect on muscular fatigue, 306.
- properties, effect of salts, N.Y.State 165.
- used in textile sizing, comparison with starches, U.S.D.A. 460.

Genes—

- phy-icochemical picture, 25.
- structure and general organization of inheritance, Iowa 27.

Genetics—

- in the U. S. S. R., 190.
- International Congress of, notes, 160.
- physiological aspects, 355.
- principles, treatise, 23.
- Society of America, meetings, papers, 190, 192.

Genus as natural category, 485.

Georgia Coastal Plain Station, report, 461.

Georgiaphis ulmi on elms, Fla. 238.

Geranium—

- diseases in greenhouse, Wash. 222.
- propagation, Mass. 512.

German-Rumanian economic agreement, U.S. D.A. 432.

Ghardomyia rhododendri on rhododendron, description, 682.*Gibberella saubinetii*, variation in, 380.

Ginger lily, production tests, Fla. 200.

Ginkgo, pollen longevity, 25.

- Girls, rural, greater cash income for, a community problem, Miss. 887.

Gizzard—

- erosion and growth in chicks, effect of chondroitin sulfuric acid, 263.
- erosion in chickens, West.Wash. 424.
- lesions, nutritional, in chicks, 696, Mass. 560.
- lining, erosions of chicks, effect of bile acids, 409.
- worm, additional intermediate hosts for, Hawaii 671.
- worm, parasite of ruffed grouse, Mich. 805.

Gladiolus—

- diseases, new, 233.
- elongation rate of stems, effect of temperature and sunlight, 181.
- growth and flowering, effect of corm characteristics, Iowa 520.
- thrips, biology, habits, and distribution, Calif. 245.

- thrips, control, Fla. 238, U.S.D.A. 242.
- varieties and storage, Fla. 210.

Glasses, Lovibond red and Lovibond 35 yellow, departures from additivity among, 380.

Gloeosporium—

- black canker, Tex. 51.
- cane canker of rose, Tex. 51.
- perennans*, notes, 665.

Glonopsis elliptica n.sp., description, 535.

- Glucose infusion through external pudic artery, effect on lactose secretion in milk, 412.

Glumedra n.g. and n.spp., description, 394.

- Glycine injections in dogs, heat production and blood and urine constituents after, 556.

Glycine toxicity, 257.

Glyptodrilus annandalei, anatomy, 809.*Gnorimoschema lycopersivella*, see Tomato pinworm.

Goat lice, notes, Tex. 67.

Goats—

- Angora, inheritance studies, Tex. 28.
- cestode parasites in Punjab, 809.
- dairy, blood composition, 568.
- dairy, genetic study, 192.
- dairy, partition of serum globulins, 700.
- development of resistance to *Cooperia curticei* in, 570.
- milk v. cow's milk, composition and properties, U.S.D.A. 564.
- purebred Toggenburg, effect of outbreeding and inbreeding, N.Mex. 832.
- pyogenic infection in Tanganyika, 110.
- reproduction, effect of decreased body reserves of vitamin E, 402.
- vitamin A requirements, Tex. 87.

Goiter—

- incidence and iodine distribution, 602.
- production in chickens, 263, 425.

Goldenrod, rayless, chemical composition, 324.

Goldfish, phenotypes, color pattern, effect of ultraviolet radiation, 192.

Gonad—

- activity of English sparrow, effect of diet, 197.
- stimulation in ferrets, visual pathways concerned in, 196.

Gonadotropic secretion in parabiotic rats, effect of antigonadotropic sera, 198.

Gonads, effect on reproduction and lactation cycles, 359.

Gonatopus n.sp. attacking *Baldulus maidis* in Puerto Rico, P.R.Col. 235.*Gonipterus scutellatus*, notes, 72.

Gooseberry mildew control, Idaho, 655.

Gopher, susceptibility to *Leptospira icterohaemorrhagiae*, 571.

Gossypium—

- distribution and evolution of commercial cottons, 205.
- genetics and application to cotton breeding, 205.
- genus, relations in, 191.

Government—

- county and municipal, of Tennessee, 137.
- local, in rural Ohio counties, Ohio 291.

Grafting, cleft and whip methods, Miss. 787.

Graftwood, storing, best time for, Miss. 787.

Grain—see also Cereals and Oats, Rye, Wheat, etc.

- crops, effects of grain sorghum and corn preceding, Tex. 37.
- crops, small, in Corn Belt, possibility of substituting hay and pasture crops for, Iowa 121.
- date of seedling tests, Wis. 502.
- diseases in Texas, U.S.D.A. 655.
- diseases in Virginia, U.S.D.A. 525.
- distillers', and concentrated slop, nutritive value, 89.
- dried distillers' and dried brewers', for fattening pigs, Del. 254.
- drying in windrows before combining, Wis. 118.
- fineness of grinding, effect on coefficients of digestion in dairy cows, S.Dak. 265.

Grain—Continued.

- handling methods and merchandising of farmers' elevators, Iowa 121.
- loose smut, U.S.D.A. 378.
- pests, 674.
- rust, breeding for resistance, Tex. 50.
- rusts, U.S.D.A. 378.
- seleniferous, toxicity, effect of arsenic in diet, 84.
- small, irrigation at germination reducing yields, Colo. 37.
- small, varieties for North Dakota, N. Dak. 201.
- specialized strains of parasites and genetic relations, 224.
- spring, response to fallow and tillage practices, Nebr. 639.
- storage program of Poland, U.S.D.A. 292.
- stored, insects infesting, Minn. 71.
- stored, pests in Japan, 71.
- stored under proposed ever-normal granary plan, insect hazards and preventive measures, 806.
- straw, combine, plowed under, effect on following crops, Wis. 502.
- trade, overseas, shipping and freight rates in, 294.

Granary—

- ever-normal, proposed for Germany, U.S.D.A. 432.
- weevil, biology and control, 81.

Grape—

- California vine disease and red leaf, Calif. 220.
- diseases in New York State in 1938, 231.
- diseases on New York market, U. S. D. A. 48.
- fruit rots, Fla. 221.
- insect research, recent developments, 806.
- juice, canning, N.Y.State 165.
- juice, sulfured and nonsulfured, vitamin C in, 744.
- or vine thrips, biology, habits, and distribution, Calif. 245.
- red leaf disease in California, control, 539.
- rootstocks, S.C. 41, Tex. 41.
- rootstocks, insect-resistant, development, Calif. 210.
- stocks, resistance to root rot, Tex. 52.

Grapefruit, composition, rootstock effect, 518.

Grapes—

- breeding, Calif. 210.
- breeding, 47 years of, at Geneva, N.Y. State 792.
- color in, Calif. 165.
- culture, propagation, and pruning, N.Y. State 213.
- in Arizona, Ariz. 519.
- maturity studies, Calif. 210.
- muscadine varieties, Ala. 39.
- pollination, Tex. 41.
- uneven ripening, causes, Okla. 40.
- varieties, Okla. 40, S.C. 41.
- variety tests, Ga.Coastal Plain 374, La. 645.

Grapes—Continued.

- vinifera, bud-graft method of propagating on rootstocks, U.S.D.A. 44.
- wine, pruning, Calif. 210.
- wine, temperatures for, Calif. 210.

Grapevine—

- aphid, biology and control, Fla. 238.
- moth parasite, 82.

Grapevines, cultural requirements, Nebr. 645.

Graphium ulmi, see *Ceratostomella ulmi*.*Graphocephala coccinea* on rhododendron, 395.*Grapholitha*—

- funebrana*, morphology, life history, and control, 397.
- inopinata*, notes, 397.
- molesta*, see Fruit moth, oriental.
- packardii*, see Cherry fruitworm.

Grass—

- and grass drying, value, Del. 200.
- and legume seedlings planted at different depths in five soil types, emergence, 201.
- growing under trees, 505.
- juice factor, properties and behavior, Wis. 87.
- juice factor, rations for guinea pigs suitable for assay of, 405.
- mite, nuclear cytology, 464.
- perennial, new variety, Idaho 638.
- seeds, southern, scarification studies, 373.

Grasses—see also Grassland, Lawns, Meadows, Pastures, etc.

- adaptability to subsoil v. fertile top soil, Iowa 34.
- adaptation studies, Hawaii 638.
- Bahia and centipede, effects of fertilizer formulas on yields, Fla. 200.
- breaking rest period with potassium thiocyanate and stimulating growth with artificial light, 638.
- breeding, Ga.Coastal Plain 363, Pa. 35.
- carotene in, effect of drying methods, 256.
- comparison for root systems, 201.
- culture and range improvement in Great Plains, U.S.D.A. 202.
- culture experiments, Okla. 35.
- elephant, nutritive values, P.R.Col. 255.
- fertilizer experiments, R.I. 775.
- for pasture and hay, N.Dak. 364.
- forage, breeding, Wash. 201.
- forage, diseases, Wash. 222.
- forage, susceptibility to cereal smut fungi, 382, 657.
- grasslands, and fodders in India, bibliography, 641.
- grown on cut-over sand hill land, grazing test, Fla. 200.
- native and adapted, for soil conservation and moisture in Great Plains, U.S.D.A. 202.
- native, relative palatability, Hawaii, 687.
- new, grazing tests, Tex. 37.
- nitrogen content, effect of nitrogenous fertilizer, 776.

Grasses—Continued.

- of Hawaiian ranges, Hawaii 640.
- on hillside and lowlands, variously fertilized, forage production, P.R.Col. 502.
- pasture, composition and vitamin content, Mass. 562.
- pasture, grazed at successive intervals, chemical composition and nutrient yield, 703.
- pasture, growth and composition, effect of temperature, Mo. 503.
- pasture, improvement, 26.
- pasture, response to day length and soil moisture, R.I. 775.
- perennial, response to cutting treatments, 777.
- range, behavior and composition, effect of burning, Fla. 200.
- range, carotene in, monthly variation, 555.
- range, composition, N.Mex. 825.
- response to fertilizer treatments, La. 639.
- response to intensity of clipping, Nebr. 640.
- Rhizoctonia* disease, 228.
- seed production tests, Idaho 638.
- seed yields, effects of row spacing, Idaho 638.
- seedling, susceptibility to grasshopper damage, 640.
- snow scald, organisms causing, [N.Y.] Cornell 49.
- sod-forming, establishment on logged-off land, Oreg. 35.
- turf, fertilizer experiments, Pa. 36.
- variety tests, Alaska 362, Fla. 200, Ga. Coastal Plain 363, Idaho, 638, Okla. 35, R.I. 775, Tex. 37, Wash. 201, Wyo. 503.
- zinc content, 226.

Grasshopper—

- baits, new information, Wis. 541.
- eggs and larval predators, degree of survival after drying and low temperatures, N.Dak. 72.
- eggs, changes in radiosensitivity during early development, 72.
- eggs, oxygen consumption and rates of dehydration, 73.
- flights, determination, painting for, 678.
- lesser migratory, Conn.[New Haven] 540.
- lesser migratory, insecticides and insect toxicology, Iowa 65.
- plague, egg parasite of, 73.
- plague, morphology, biology, and control, 544.
- plague, vegetation types associated with in South Australia, 515.
- two-striped, poison baits for tests, 544.

Grasshoppers—

- control, Nebr. 672.
- control by poison bait and fungus disease, Okla. 68.
- control by sawdust baits, Wis. 541.
- control by tillage and seeding methods, U.S.D.A. 242.

- Grasshoppers—Continued.
 dried, for poultis, value, Okla. 86.
 emergency studies, Iowa 65.
 feeding castor-bean leaves to, Okla. 35.
 in Philippines, studies, 811.
 injury to shelterbelt plantings, N.Dak. 813.
 of South Dakota, life histories and control, S.Dak. 239.
 outbreaks in Australia, 244.
 outbreaks in Missouri, Mo. 815.
- Grassland—see also Grasses, Meadows, and Pastures.
 insects, interesting data. 806.
 major changes as result of continued drought, 776.
 studies, 751.
- Gray scale on papaya trees, control, P.R.Col. 541.
- Grazing—see also Range.
 lands, privately owned and public lands, economic relation, 290.
 steers on lowland and upland permanent pastures, Ga.Coastal Plain 404.
- Green manure—
 crops, [N.Y.]Cornell 42.
 crops, tests for truck soils, S.C. 36.
 leguminous, decomposition in acid and limed soils, Iowa 13.
 notes, 892.
 role in potato production, 206.
 use, Fla. 170.
- Greenhouse—
 soils, management, 15.
 thrips, biology, habits, and distribution, Calif. 245.
 thrips, toxicity of dinitro-o-cyclohexyl-phenol to, 676.
- Gregarina* spp., parasites of yellow mealworm. 81.
- Grevillea seeds, whole mounts of endosperm from, dissection and preparation, 184.
- Group classification based on structure, 727.
- Grouse—
 artificial incubation of eggs, 264.
 eastern ruffed, studies, Mich. 804.
 sage, new nematode from, 709.
 sharp-tailed, of Wisconsin, 804.
- Growth substance(s)—see also Plant growth substances.
 applied, identification, 180.
 new, β -naphthoxyacetic acid, 768.
- Grylloblatta campodeiformis*, notes, 672.
- Gryllotalpa hemadactyla*, see Cricket, northern mole.
- Guava algal leaf spot, Fla. 222.
- Guinea pig—
 colony, controlled epidemic in, 887.
 dominance in E series of, 192.
 muscles, scorbutic, lactic acid formation by, 257.
- Guinea pigs—
 female, ovarian condition and sexual behavior in, 498.
 inbred and crossbred, weights and measurements of parts and organs, 193.
- Guinhen, hybrid resulting from crossing guinea hen and male chicken, 636.
- Gymnosporangium clavipes*, notes, U.S.D.A. 48.
- Gynaecogenic, suggested use of term, 30.
- Gypsy moth—
 control, opportunity for forestry practice in, 817.
 control, spraying with autogiro for, 680.
 studies, Me. 67.
- Habranthus robustus*, notes, Tex. 41.
- Habronema megastoma*, biology, 836.
- Haddock muscle—
 decomposition rate at various temperatures, 302.
 rate of decomposition at various temperatures, Mass. 604.
- Haematobia irritans*, see Horn fly.
- Haemonchus contortus*—
 and *Moniezia capensis* in a young goat, 844.
 immature, anthelmintic efficiency against, 843.
 sterile culture of, 105.
- Hacmoproteus*—
 columbae of North American doves, 683.
 maculatum in mourning doves, 105.
 sacharovi in pigeons and mourning doves, 105.
- Hair pigments, determination in mice, 192.
- Halotydeus destructor*, population study in Western Australia, 83.
- Hams—
 frozen, curing, Pa. 86.
 home-cured, storing methods, Tex. 87.
- Hares, varying, parasitological reconnaissance in Alaska, 669.
- Harlequin bug, control, 544.
- Hawaii Station, report, 750.
- Hawks, North Dakota, value to agriculture, N.Dak. 539.
- Hay—see also specific kinds.
 air dried, making and feeding to dairy heifers, 703.
 alfalfa and timothy, relative efficiency for growing lambs, 92.
 chopped, ventilation equipment for, Wis. 116.
 clover v. timothy, Ind. 773.
 curing time, reduction by mower-crusher, middle buster used for, Miss. 850.
 drying, cost, Wash. 287.
 early cut artificially dried, for dairy cows, Vt. 412.
 effect of quality and variety on dairy heifers, [N.Y.]Cornell 96.
 fertilizer experiments, Pa. 36.
 oat-and-pea, for fattening pigs, Alaska 403.
 of various kinds, comparison for milking cows and sheep, Alaska 404.
 quality, effect of curing and handling, Miss. 774.
 quality, improving, 364.
 seeding mixtures, comparisons, Mass. 501.

Hay—Continued.

yields, Alaska 362.

yields, response to nitrogen carriers on limed and unlimed soil, Pa. 36.

- Labor—*see also* Agricultural labor.
 human, mechanical power displacing to ever-increasing extent, Miss. 850.
 income on northwestern Indiana farms, Ind. 721.
- Laboratory column packings, silicon carbide for, 472.
- Lac industry, biological control in, 809.

Lactation—

- endocrines related to, 498.
- in virgin rabbits, effect of injection of urine from pregnant cattle, 31.
- initiation in albino rat with lactogen and adrenal cortical hormone, 773.
- physiology of, [N.Y.] Cornell 96.
- promoting effect of l-cystine fed with alfalfa proteins, 405.
- specific nutritional factors in, 266.

Lactic acid—

- bacteria, nitrogen and accessory growth factor requirements, Iowa 4.
- bacteria, properties of new growth factor for, 492.
- bacteria, studies, Wis. 4.
- formation by muscles of scorbutic guinea pigs, 257.
- industrial production, Wis. 4.
- production, use of agricultural products in, Iowa 4.

Lactobacillus casei cultures, nitrogen metabolism, Iowa 96.Lactoflavin, *see* Riboflavin.

- Lactose, α - and β -, relative amounts in dried milk and whey, [N.Y.] Cornell 6.
- Lactose, β -, crystalline, seeding test for detection, [N.Y.] Cornell 6.
- Lactuca* spp., cytogenetic observations in, 191.

Ladybeetle—

- Chinese, introduction and propagation, Fla. 238.
- convergent, attempt to colonize, 812.
- Laelitia coccidiivora*, notes, Fla. 238.

Lamb—

- home-killed, curing methods, Okla. 85.
- legs, cured, moisture and salt distribution in, effect of aging, 403.
- organs and tissues, distribution of flavin and antipellagra factor, S.Dak. 304.
- resulting from use of purebred mutton rams on native ewes, 407.
- tenderness and flavor in, effect of degree of fatness, Tex. 87.

Lambs—

- choice spring, from good pasture, Miss. 825.
- Creep-feeding, returns from, Okla. 85.
- crossbred, wool- and mutton-producing qualities, Wyo. 554.
- dysentery, Wash. 274.
- ewe, breeding, N.Dak. 826.
- fattening—
 - corn v. cottonseed meal and prairie hay v. alfalfa for, Okla. 85.
 - cutting hay for, value, Ind. 688.
 - distillers' corn dried grains and brewers' dried grains for, [N.Y.] Cornell 85.
 - overeating a serious problem, Colo. 92.
 - rations, amount of cottonseed meal supplement, N.Mex. 825.
 - rations, comparison, Nebr. 689.
 - rations, sugar beet byproducts in, S. Dak. 255.

Lambs—Continued.

- fattening—continued.
 - rice byproducts and molasses for, value, La. 688.
 - stock berths for, value, Calif. 254.
- fleece of different body regions development of characters, 92.
- grazing, absence of ill effects under sprayed and dusted pecan trees, Okla. 68.
- helminth parasites of in Ontario, 110.
- hothouse, production, Pa. 86.
- mineral deficiency studies, 404.
- newborn, blood sugar and ketone content, 258.
- on wheat pasture, returns for feeding grain to, Okla. 85.
- phosphorus requirements, Idaho 688.
- prices, index number, N.Dak. 131.
- protein concentrates for, comparison, Idaho 688.
- Rambouillet ram, reproductive capacity as indicated by semen tests, 497.
- range, maintenance and fattening rations, comparison, Wyo. 554.
- relative efficiency of proteins from alfalfa and timothy hay, 92.
- soybean oil meal for, optimum levels, Pa. 86.
- stiff, and white muscle disease, 422.
- stiff disease in Michigan, 715.
- stiff joint ailment, good management for correcting, Okla. 85.
- stiff, relation to feeding and management, [N.Y.] Cornell 85.
- supplying phosphorus for, efficiency of farm-grown feeds, Idaho 688.

Land—*see also* Farm land.

- abandoned, revegetation, Nebr. 617.
- adapted, poorly adapted, and not adapted to agriculture, Ohio 482.
- arable, relative absorption of nutrients by weeds, 786.
- classification, Calif. 166, Iowa 13.
- classification for best use, economic criteria, 585.
- credit, *see* Agricultural credit.
- eroded, protection by revegetation, Tex. 14.
- forest, *see* Forest lands.
- grant colleges, *see* Agricultural colleges.
- irrigated, drainage and methods of reducing canal losses, Idaho 719.
- irrigated, of Humboldt River area, Nev. 851.
- ownership in North Dakota, N.Dak. 854.
- ownership in Nowata County, Okla. 585.
- ownership map, method of preparing and uses, Okla. 122.
- problem-area groups in southern Great Plains, U.S.D.A. 171.
- problem in Mexico, U.S.D.A. 292.
- rent, overlooked aspect of, 290.
- rents and land values in Italy, 481.
- ridding of objectionable growths and obstacles, Fla. 200.

Land—Continued.

- submarginal, in Great Plains, Federal purchase and administration, 430.
- surfaces, evaporation from, U.S.D.A. 333.
- tax delinquent rural, unsuited for agriculture, Ohio 432.
- tenure and social control of land use, 853.
- tenure of western Slavs, 854.
- tenure, seigniorial, in Canada, 854.

- use in California, U.S.D.A. 434.
- use in Europe, public control, 430.
- use in Manitoba, 724.
- use in southern Alberta, 434.
- use in Taylor Co., Ky. 585.
- use in tobacco area of southern Maryland, Md. 855.
- use in United States, public control, 430.
- use problems, 431, 434, Mas. 565.
- values and Government agricultural policy, 431.
- values, monetary policy in relation to, 431.

Laphygma—

exempta on corn in Java, 393.

exigua, see Armyworm, beet.

Larch sawfly, control, Mich. 253.

Lard—

- characteristics, relation to culinary value, Iowa 861.
- hydrogenated, as culinary fat, Ind. 736.
- keeping quality, effect of soybeans and their products, Iowa 84.
- open-kettle, antioxidant effect of thymol, Iowa 140.

Larkspur bacterial bud rot and blight, Calif. 220.

Larkspurs, garden, treatise, 217.

Larva americana, establishment in Puerto Rico, 686, P.R.Col. 541.

Larvicides, notes, Tex. 67.

Laryngotracheitis—

- in poultry, Oreg. 103.
- infectious, in New South Wales, 107.
- virus, egg-propagated, viability and immunizing value, 418.

Laspeyresia funebrana, morphology, life history, and control, 397.

Lawn weeds, control, R.I. 775.

Lawns, development and care, Mo. 520.

Lead—

arsenate—

- replacing with insecticides nonpoisonous to man for apple pests, Wash. 289.
- retention on apples, effect of petroleum oil and of lime-sulfur, 809.
- substitutes in orchard sprays, 671, Conn.[New Haven] 540.
- metabolism and retention in rats, 397.
- residue from spray schedules and materials, 818.

Lead—Continued.

- residue retention by rats, effect of apple constituents, 873.
- tolerance of animals for, 106.

Leaf—

- areas, measuring, photoelectric device for, 493.
- blades, carbohydrate transformations in, 766.
- roller control, promising modified oil sprays for, Wis. 541.
- streak disease, Tex. 51.
- structures, tissue organization and vein distribution in, 347.
- temperatures, effects of drops of water on, 20, 181.

Leaf-footed bug, control on Satsuma oranges, Fla. 238.

Leafhopper—

- greenhouse, biology and control, 245.
- on green beans, control, 807.
- six-spotted, pyrethrum and derris for control, 545.

Leafhoppers injurious to rice in Japan, 545.

Leafroller, control, 671.

Leaves—

- absorption of radiant energy by, 181.
- action of copper on, 353.
- condition of chlorophyll in, 628.
- green, metabolism of proteins in, 22.
- growth factors, activity of pure substances in, 768.
- starch dissolution and amylolytic activity in, 492.
- stomatal openings and intercellular spaces, relative humidity of, 181.
- transpiration rate and stomatal index, 20.

Lecanium, European fruit, control, Okla. 68.

Legislation relating to agriculture, development in Ohio, 432.

Legume—

- and grass seedlings planted at different depths in five soil types, emergence, 201.
- bacteria, vitamins for, Wis. 14.
- inoculants, inspection, N.Y.State 209, N.J. 511.
- nodule development, relation to available energy supply, 487.
- roots, excretion of nitrogen from, Wis. 14.
- seeds, impermeability and viability, 372.
- symbiosis, carbohydrate-nitrogen relation in, 622.

Legumes—see also Green manure and Alfalfa, Clover, etc.

- adaptability to subsoil v. fertile topsoil, Iowa 34.
- and associated organisms, [N.Y.]Cornell 622.
- effect of lime and basic slag, Miss. 762.
- erosion control and wildlife values, U.S.D.A. 803.
- fertilizer requirements, Miss. 774.
- for green manure for corn and oats, tests, Iowa 34.

Legumes—Continued.

- for pa-ture and hay, N.Dak. 364.
- improvement, 26.
- inoculation requirements, Miss. 774.
- inoculation studies, Fla. 200, Tex. 37.
- new for pastures, Tex. 37.
- pa-ture, inoculation tests with, Tex. 37.
- pasture, studies, Fla. 201.
- pollination and nodulation, relation, 364, 487.
- seedling stands, effect of pythiaceus and other fungi, Iowa 48.
- symbiosis with legume bacteria, 691.
- value for poorer soils, Miss. 761.
- variety tests, Alaska 362, Fla. 200, Okla. 35, P.R.Col. 502, Tex. 37.
- winter, as green manure, N.Mex. 775.
- winter hardiness, tests, Alaska 362.
- winter, nitrogen in, Miss. 774.
- winter, time for plowing under, Miss. 774.
- winter, value, Miss. 774.
- winter, variety tests, La. 639.
- Leguminosae, classification, relation to anatomy and cytology, 181.
- Leis dimidiata ispidota*, introduction and propagation, Fla. 238.
- Lemon—
 - rootstock experiments, 519.
 - trees, premature decline in, causes, Calif. 210.
- Lemons—
 - composition, rootstock effect, 518.
 - growth of fruits, relation to soil moisture, U.S.D.A. 652.
 - Meyer, chromosome structure of, Tex. 41.
 - yields, effect of rootstocks, Calif. 210.
- Lentil varieties in Palestine, 464.
- Lepidoptera—
 - apparatus and method for filling larvae with wax, U.S.D.A. 240.
 - food plants of larvae, 672.
 - larvae intercepted at quarantine, identification, keys, U.S.D.A. 806.
 - of boreal America, check list, 819.
- Leptidosaphes beckii*, see Purple scale.
- Leptinotarsa decemlineata*, see Potato beetle, Colorado.
- Leptoglossus phyllopus*, see Leaf-footed bug.
- Leptomastix* n.sp., parasitic in *Phenacoccus hirsutus*, 809.
- Leptospirosis in dogs, 718.
- Lespedeza—
 - dodder control on, 644.
 - fertilizer and liming studies, La. 639.
 - hay v. alfalfa for bred ewes, Ky. 553.
 - Korean, adaptation studies, Iowa 38.
 - Korean, limestone mobilizes phosphates into, 642.
 - Korean, selection and improvement, Del. 200.
 - leading forage crop for hay growth, Miss. 774.
 - response to lime and fertilizer, 779.
 - stands, effect of wide v. narrow small grain rows, Okla. 35.

Lespedeza—Continued.

- variety tests, Ga.Coastal Plain 363, La. 363, Tex. 36.
- Lespedeza sericea*—
 - cutting, frequency, Ala. 33.
 - seasonal variation of tannin in, 5.
- Lettuce—
 - absorption of chemical elements important in human nutrition, Mass. 477.
 - available iron in, 596.
 - breeding, Pa. 40.
 - diseases, U.S.D.A. 373.
 - fertilizer experiments, Ga.Coastal Plain 374.
 - Iceberg, problems in production, [N.Y.] Cornell 42.
 - improvement, [N.Y.] Cornell 42.
 - Pythium* stunt, U.S.D.A. 655.
 - seed, dormant, stimulation of germination, 790.
 - seedlings, response to 7600A radiation, 351.
 - spotted wilt disease, 383.
 - time of planting, N.Mex. 787.
 - variety tests, Ga.Coastal Plain 374, E.I. 788, Wis. 512.
 - wind injury to, U.S.D.A. 655.
 - yellows transmitted by six-spotted leaf hopper, 545.
- Leucocytozoon*—
 - donaseae*, parasite of ruffed grouse, Mich. 803.
 - smithi* in turkeys, 848.
- Leuconostoc mesenteroides*—
 - effect on factory cane juices and sirups, 228.
 - from frost damaged sugarcane, effect on cane juice and sirup, 758.
- Leucopsis griseola*, biology and morphology, 73.
- Leucoptera coffeella*, notes, P.R.Col. 541.
- Leucosis—
 - fowl, causative agent, 719.
 - fowl, migration of etiologic agent when subjected to electrophoresis, 113.
 - fowl, symptoms, pathology, and transmission, 846.
 - in chicks, transmission, Ind. 707.
- Lenkemia—
 - chronic myeloid, of a hog, 575.
 - transmission, West.Wash. 424.
- Libraries and illiteracy and reading habits in Tennessee, 298.
- Life, length of and composition of body, relation to nutrition, 451.
- Light, distribution in beech stand, 335.
- Light, increased, effect on ovarian development in English sparrow, 358.
- Ligniera vasculorum*, notes, 228.
- Lignin—
 - adhesive properties, 474.
 - aerobic decomposition by lake bacteria, 621.
 - in soils, decomposition, Iowa 13.
 - new byproducts from, 474.
 - relation to mineral absorption by plants, Mass. 477.

Lilies—

- culture, B.I. 787.
- forcing, effect of temperature, Mass. 512.
- Lilium formosanum*, disease and pest control, R.I. 795.

Lily thrips, biology, habits, and distribution, Calif. 245.

Lima beans, see Beans, lima.

Lime—

- products, inspection and analysis, Mass. 846.
- studies, Nebr. 617.

Lime(s) (fruit)—

- composition, rootstock effect, 518.
- tree bark disease, Tahiti, Fla. 221.

Limestone—

- dolomitic, decomposition in soils, 327, 343.
- soils derived from, U.S.D.A. 760.

Lime-sulfur—

- dry and liquid, insecticidal values, Wash. 239.
- substitutes in summer sprays for orchards, Mass. 540.

Liming experiments, 16.

Limonius—

- californicus*, see Sugar beet wireworm.
- octypus*, see Wireworm, eastern field.

Linkage—

- in rats, 192.
- of pea comb and blue egg in fowls, 772.

Linseed—

- midge, chalcid parasite of, 811.
- midge, new chalcidoid parasites of, 823.
- oil and meal, factor responsible for finish on fattening steers, Iowa 84.

Liothrips—

- concoctei*, notes, Calif. 245.
- variicornis*, notes, Calif. 245.

Lipase action in milk, 413.

Lipurus capensis, notes, Ky. 540.

Lipurus heterographus, see Chicken head louse.

Lipman, J. G. editorial, 1.

Lippia anthracnose, 667.

Liquors, noninflammable, concentration, anti-foaming device for, 325.

Listeria—

- and *Erysipelothrix*, comparative study, 571.
- group, bacteria isolated from foxes, 424.
- monocytogenes* infection in animals and man, 839.
- strains, flagellar antigenic structure of, 571.

Listroderes obliquus, see Vegetable weevil.

Liver—

- abscesses in cattle, bacteriologic study, 279.
- extract, use in place of yeast in low fat diets, 690.
- flake, development in final host and longevity, Hawaii 671.
- flake infestation in cattle and sheep, 836.
- flake, intermediate snail host, control, 714.

Liver—Continued.

- flake of cattle and longevity of cysts, Hawaii 671.
- lactagogue factor in, Iowa 140.

Livestock—see also Animals, Mammals, Cattle, Sheep, etc.

- auctions in Ohio, 438.

diseases—see also Animal diseases and specific kinds.

- laboratory diagnoses, Ind. 707.
- effects of climatic factors, 402.
- long-range insemination, problems in, 497.

market, central, changing relative importance, 438.

marketing cooperatives, decrease in number, Iowa 120.

marketing methods and prices, 430.

marketing, public regulation, Iowa 120.

markets, types and price structure, 430.

mineral deficiencies in, new approach to problem, Miss. 825.

poisoning, see Plants, poisonous, and specific plants.

production, principles and application of genetics to, 193.

purchases outside the State, Ala. 120.

shipping associations, Minn. 130.

statistics, see Agricultural statistics.

work stock project in Georgia, 402.

Livia opaquia allotype, description, 679.

Lixophaga diatraea, attempts to establish in Louisiana and Florida, 812.

Lixus—

- brachyrrhinus*, notes, 811.
- enemies of sugar beet in Morocco, parasite of, 539.

truncatulus, egg parasite of, 811.

truncatulus, life history and biology, 810.

Loco weed poisoning, Tex. 104.

Locust (insect)—

- African migratory, ecdysis in, 892.
- African migratory, growth problems, 245.
- brown and red, in Union of South Africa, 815.

brown, in an outbreak center, 815.

desert, extra hopper stage in, 810.

desert, notes, 894.

desert, rate of growth and size, 810.

outbreaks in Africa and Asia, 815.

red, notes, 894.

red, white and gray fungus disease of, 678.

reversal changes and importance of third instar, 810.

Locust (tree)—

- black arsenate injury caused by drift, Miss. 802.

black growth, effect of surface soil depth, Miss. 787.

black, plantations, effect of soil type on growth [N.Y.] Cornell 45.

black, seedlings, dodder damage, 802.

borer problem, recent developments, 806.

Locusta migratoria—

- in India, solitary phase individuals, migration, 810.

- Locusta migratoria*—Continued.
migratorioides, notes, 245, 394.
 notes, 244.
- Locustana pardalina*—
 in an outbreak center, 815.
 in Union of South Africa, 815.
- Loin disease in cattle, Tex. 104.
- Lonchocarpus*, review of literature, U.S.D.A. 242.
- Longhorn beetle on valuable furniture in Egypt, control, 80.
- Longspurs, descriptive account, 236.
- Louisiana Station, notes, 159, 463.
- Louisiana University, notes, 890.
- Louping ill virus, infection of central nervous system by, 106.
- Lucerne flea predator, 83.
- Lucilia*—
cuprina larvae, synthetic medium for aseptic cultivation, 820.
cuprina, notes, 399.
sericata, control, 400.
sericata larvae, urease in, 573.
sericata, losses due to, 79.
sericata, notes, Calif. 273.
 sp. attacking sheep, 105.
- Ludius*—
aeripennis destructor, life cycle and food requirements, 552.
divaricatus, description of larva, 821.
- Luffa ferchaultella*, habitat, distribution, and dispersal, 817.
- Lumber—see also Timber and Wood.
 production, distribution, consumption, and prices, U.S.D.A. 46, 47.
 requirements for nonfarm residential construction, U.S.D.A. 427.
 use in farm buildings, Iowa 115.
- Lungworms in pigs, course of infection, 836.
- Lupinus*—
albus seedlings, growth, effect of vitamins, 180.
angustifolius, poisonous to livestock, Fla. 273.
- Lychnis viscaria* stem rot due to *Phytophthora cactorum*, 667.
- Lycopersicon hirsutum*, mosaic-tolerant, wilt-resistant, hybridization with *L. esculentum*, 665.
- Lyctus*—
brunneus, preservation of timber against, 686.
 powder-post beetles, notes, 394.
- Lygaeonematus*—
erichsonii, see Larch sawfly.
pini, notes, 401.
- Lygus*—
 bugs, studies, 674.
 control on alfalfa seed, Idaho 671.
pratensis, see Tarnished plant bug.
 spp., relation to alfalfa seed production, Utah 74.
- Lymantria monacha*, notes, 396.
- Lymanaea philippinensis*, destruction for control and eradication of fascioliasis in ruminants, 714.
- Lymphadenitis, caseous—
 in milk goats, 575.
 notes, Calif. 273.
- Lymphangitis in horses, unrecognized forms of, 536.
- Lymphomatosis in chickens—
 experimental attempt to produce, 425.
 wheat-germ oil treatment, failure, 719.
- Lyperosia exigua* and its para-sites in Australia, 390.
- Lysimeter studies, S.C. 14.
- Lysine injections in dogs, heat production and blood and urine constituents after, 556.
- Macadamia nuts—
 morphology, breeding, culture, etc. Hawaii 614.
 processing, Hawaii 793.
- Macaria pterogata*, pest of Daincha, 811.
- Machinery, see Agricultural machinery.
- Macracanthorhynchus hirudinaceus*, localization of glycogen in, 105.
- Macrobasis albida*, notes, Tex. 67.
- Macrophomina phaseoli* on *Strophostyles helvola* in Georgia, U.S.D.A. 378.
- Macrosiphum*—
gei, notes, 816.
pisi juices, inhibition of virus activity by, 52.
roseae, notes, 670.
solanifolii, digestive system, 679.
solanifolii juices, inhibition of virus activity by, 52.
- Macrosporium*—
Alternaria, and *Stemphylium*, comparative pathogenicity and taxonomy, Fla. 221.
 and *Septoria* leaf spots, varietal susceptibility of tomatoes, 654.
carotae, notes, Tex. 52.
 new taxonomy in genus, 52.
sarcinaeforme conidia on tomato and red clover, 379.
solani, notes, Del. 221, Wis. 527.
 sp. in forest tree nurseries, U.S.D.A. 48.
 sp., notes, Calif. 220.
- Macrosteles divius* juices, inhibition of virus activity by, 52.
- Mad itch, see Paralysis, infectious bulbar.
- Magnesium
 arsenates as insecticides, U.S.D.A. 242.
 compounds, relative availability for plants, Ind. 617, B.I. 709.
 for rats, adequacy of cow's milk as source, 869.
 requirements of lactating cows, 266.
 requirements of plants, Mass. 477.
- Maine Station, notes, 160, 860.
- Maine Station, report, 157.
- Maine University, notes, 160, 604.
- Metacoeloma*—
diastria, see Tent caterpillar, forest.
fragilis, biology, 546.
- Malaria—see also Mosquitoes and Anophelinae.
 avian, immunity in, 105.
 avian, parasites in tissue sections, staining technic, 105.

- Malaria**—Continued.
control, economic importance of, 682.
in Netherlands, 78.
parasite, avian, rate of reproduction in, 710.
parasite, life cycle in mosquito host, graphic reproduction, 78.
Mal-de-caderas in Venezuela, 839.
Malnutrition, a challenge and an opportunity, 734.
Mamestra—
 brassicac, notes, 396.
 psi, morphology and biology, 396.
Mammals—*see also* Animals and specific kinds.
 birds, and reptiles, relations, standardization of precipitin technic in studies, 235
 of Idaho, 669.
 of Japanese Empire, distribution, 669.
 of Tennessee, list, 803.
Mammary gland—
 activity, 193.
 effect of testosterone on, 773.
 of cows, intact and perfused, respiratory quotients, 702.
 of rhesus monkey, response to oestrone, 195.
 site of fat synthesis in, 266.
Mammogen from prehypophyseal tissue, chemical concentration, 105.
Man and animals, relation to environment, Me. 140.
Man, calcium requirements and utilization of calcium in milk and in calcium gluconate, 739.
Manganese—
 assimilation and storage in embryo and growing chick, 411.
 availability in avian digestion, 410.
 deficiency in citrus in Florida, 801.
 deficiency in diet of hen, effect, 262.
 effects on eggshell quality, Ark. 411.
 in fruits and vegetables, Mass. 469.
 in Philippine foods, 306.
 in soil fertility and plant nutrition, Oreg. 17.
 physiological importance in organisms, 310.
 requirement for bone development of chick, 560.
 requirement to prevent perosis in chicks, amount, 262.
 requirements of rats, Pa. 86.
 requirements of turkeys, Ky. 553.
 role in plant nutrition, 352.
 role in poultry nutrition, [N.Y.]Cornell 85.
 role in prevention of slipped tendon in poultry, Wis. 87.
 utilization by chickens, 694.
Mange affecting horn of buffaloes, 836.
Mango diseases, control, Fla. 222.
Mango tree pests in Dutch East Indies, 240.
Mangoes—
 composition and storage, Hawaii 644.
- Mangoes**—Continued.
 industrial possibilities and characters, P.R.Col. 469.
 notes, 211.
 varieties, P.R.Col. 512.
Mangosteens, notes, 211.
Manure—
 and rotation experiments, Nebr. 17.
 in rotations, place in, Ind. 773.
 spreader, power-driven, low-pressure pneumatic tires on, Ind. 720.
 stable, in composts, microbiological population and decomposition, effect of temperature, 176.
 studies, Nebr. 617.
Maple—
 blight associated with pythiaceus fungus, R.I. 795.
 diseases, Conn.[New Haven] 526.
 sap, flow, factors affecting, Pa. 45.
 sirup and sugar, manufacture methods, N.Y.State 166.
 sirup, prevention of lead contamination, N.Y.State 165.
 tree, deeply girdled, translocation of materials in, 181.
Marasmius pyrinus on apples, 231.
Marasmus, enzootic, role of cobalt in, 109.
Mares, variations in oestrus and ovulation in, and breeding results, 497.
Marigolds, gravel culture in greenhouse, Ohio 519.
Market—
 gardening, *see* Truck crops.
 of Wilmington, Del. 295.
 reports, U.S.D.A. 132, 296, 444, 727, 860.
Marketing—*see also* special products.
 agencies, rural, effects of wage-hour legislation, Iowa 120.
 and agricultural adjustment, 584.
 cooperative, data, Okla. 121.
 of natural products, regulation in Manitoba, U.S.D.A. 585.
 Service, Agricultural, organization and functions, U.S.D.A. 859.
Markets—
 export, for Canadian flour, 724.
 for western farm products, conference on, proceedings, 724.
Marmot, phenomenal infestation of ectoparasites, 672.
Marshes of Delaware, vegetative cover, 682.
Marsh's disease of horses in Manitoba, 284.
Massachusetts College, notes, 463.
Massachusetts Station, notes, 890.
Massachusetts Station, report, 604.
Masseuites, processing, 758.
Mastitis—
 acute cases due to unidentified nonhemolytic streptococci, 713.
 control, 279.
 detection, indirect methods, 566.
 development and spread, Wash. 274.
 diagnosis and control, methods, N.H. 281.
 diagnosis, simplified method, 281.
 Hotis test for, new routine extending usefulness, 702.

Mastitis—Continued.

- Hotis test for, report on, 841.
- importance, relation to sanitary production of market milk, N.Y. State 267.
- infected udder quarters, bacterial development in milk from, Wash. 265.
- nonspecific, pathology and cause, 109.
- nonspecific, relation to streptococcal infection of udder, 573.
- potassium permanganate reduction test for, 421.
- preparing bovine udders for study, 281.
- role of viruses in, Wis. 101.
- serological studies, 571.
- status of knowledge, 710.
- streptococci in udder, effect of sulfanilamide treatment, 420.
- streptococci of, classification, 702, 839.
- streptococcal chronic, use of large doses of sulfanilamide in, 839.
- streptococcal, relation to milk sanitation, 705.
- studies, 566, Calif. 273, S.C. 103.
- sulfanilamide treatment, 841, Idaho 707.
- survey of dairy herds, 419.
- unpreserved udder tissue affected with, differential staining, U.S.D.A. 282.

May beetle survey, Ky. 540.

Mayhaws, growing, La. 645.

Mazola—

- antioxidant effect of thymol, Iowa 140.
- inactivating power toward vitamin A, Iowa 140.

Meadows—*see also* Grasses, Grassland, and Pastures.

- effect of potash top dressing, Mass. 501.
- improvement of species for reseeding, Nebr. 640.
- improving stands by use of cultipacker seeder, Wis. 502.

Mealworm, yellow, gregarious parasites of, 81.

Mealybug—*See also specific host plants.*

- Kenya coffee, studies, 75.
- orchard, parasite of, biology, 823.
- wilt of pineapples, 330.

Mealybugs in South Africa and host plants, 395.

Meat—*see also* Beef, Lamb, Pork, etc.

- and meat products as essential dietary factors, 403.
- canned, chemical studies, 302.
- canned, processing, Tex. 141.
- in animal and human nutrition, 861.
- products, vitamin B₁ distribution in, 741.
- products, vitamin B₂ in, effect of methods of cooking, Wis. 142.
- quality studies, Nebr. 404.
- research, cooperative, conference on, 400.
- research, problems in, 302.
- storage in community cold-storage lockers, Wash. 255.
- stored in frozen condition, changes in, Mass. 591.
- tender, notes, 404.
- tenderness, effect of oven temperatures, Tex. 141.

Meat—Continued.

vitamin B₁ in, 741.

world production, 444.

Medical care and sickness among Negro population in delta area, Ark. 447.

Megastignus brevitatus, morphology and biology, 823.

Melosis in a spore-forming bacillus, 489.

Melampsora farlowii, notes, 300.

Melandrium polyploids, sex mechanism in, 357.

Melanomata in domesticated animals, 337.

Melanoplus—

divittatus, *see* Grasshopper, two-striped
mexicanus mexicanus, notes, Conn. [New Haven] 540, Iowa 65.

Melasoma populi, life history and control, 400.

Melilotus as soil-building crop, Calif. 200.

Melolontha vulgaris, parasite of, 684.

Melon, Chinese, inheritance of new sex forms in, 192.

Melon sick soils, substitute crops for, Iowa 40.

Melons, precooling prior to long-distance shipments, Calif. 210.

Mendelian—

class frequencies, interpretation, 494.
distributions, rapid analysis, graphic method for, 494.

Menhaden fish meal feeding, effect on turkey meat flavor, Va. 830.

Meningoencephalitis, treatment with sulfanilamide, 578.

Menopon gallinae, notes, Ky. 540.

Mesa dropseed, carotene in, monthly variation, 555.

Mesocostoides lineatus, notes, 837.

Metabolism, nitrogen, calcium, and phosphorus, on low-protein and on medium-protein diet, 595.

Metagonistylum minense—

colonization and bionomics in British Guiana, 683.
colonization in Puerto Rico, 812.

Metastrongylus—

eggs of swine, detection methods, 837.
of swine, course of infection, 838.
of swine, morphology and systematic position, 836.

Meteorological—

fronts and occlusions, apparatus for demonstrating, 168.
observations, Alaska 461, Fla. 168, Me. 12, R.I. 888, U.S.D.A. 168, 336.
records, Ga. Coastal Plain 336.
report for State College, Pa. 12.
service of future, 614.
studies and observations by Florida Station, Fla. 168.
work and historical sketch of Nebraska Station, Nebr. 336.

Meteorology—*see also* Climate, Rainfall, Temperature, Weather, etc.

and agriculture, 474.

papers on, U.S.D.A. 167, 168, 336.

Meteorus dumbletoni from Tasmania, description, 824.

- Methyl bromide for fumigation of plants in soil beds, 814.
- Methylene blue in milk, potentiometric studies, 702.
- Metritis of cats, septic, treatment with sulfanilamide, 849.
- Mice—*see also* Rodents.
 abnormalities of diaphragm causing death from asphyxia, 30.
 helminth parasites of, 391.
 hereditary changes in, induction by irradiation with neutrons, 193.
 immunity to *Salmonella* spp., correlation between antibody formation and resistance, 30.
 litter size, effect of parity, 500.
 mortality during suckling period, relation to litter size and parity, 500.
 relation of color genes to size in, 193.
 tail-spotting, selection for, 193.
- Micellar concept, 184.
- Michigan Station, report, 731.
- Microbiology—
 bibliography of, U.S.D.A. 19.
 introduction to, 763.
 Third International Congress for, editorial, 609.
- Microbracon*—
analoidis, notes, Ky. 81.
greeni longevity, effect of different sugars, 810.
greeni, mass breeding, 811.
pygmaeus, parasite of cherry casebearer, 680.
- Microcephalothrips abdominalis*, notes, Calif. 245.
- Mitrococcus* resistant to freezing in frozen vegetables, 303.
- Microfilariasis, cutaneous, in Indian cattle, 887.
- Microgaster tibialis*, technic and equipment for handling to prolong hibernation, U.S.D.A. 242.
- Microlychnis pusilla*, vector of dove *Haemaphysalis*, 685.
- Mioromyza oliveri* as greenhouse pest, 539.
- Micro-organisms—*see also* Bacteria.
 development on new standard milk agar, importance to dairy industry, 701.
 effect of low velocity electrons on, 182.
 enzymes of, Wis. 4.
 growth in shake cultures under increased oxygen and carbon dioxide tensions, 490.
 lipolytic, Nile blue culture medium for, 184.
 seed-borne, control, N.Y.State 222.
 thermophilic, decomposition of plant residue in composts by, 342.
- Microphotometer, new, for analysing X-ray diffraction patterns of raw cotton fiber, 459.
- Microplasma* powdery mildew of blueberries, 388.
- Microtome knives, new sharpening back and procedure of sharpening for, 184.
- Mildews, powdery, control with water spray, 58.
- Milk—
 abnormal composition, 413.
 abnormal flavors, cause and remedies, Ind. 699.
 abnormal, unidentified constituent in, 100.
 acidity, relation to fat content, 704.
 activated flavor in, cause, 413, Wis. 97.
 and cream testers, manual for, Md. 268.
 and fat production, persistency and inheritance of, Iowa 27.
 and products, improving flavor and keeping properties, Mass. 562.
 and products, lecithin content, variations in, Ind. 699.
 as public utility, duplication of distribution, Mass. 585.
 ascorbic acid in [N.Y.]Cornell 96.
 bacteria, effects of high voltage on, 268.
 bacteria, physiological types, relation to reduction of methylene blue, 566.
 bacteriological counts, comparison of media for, Pa. 97.
 bacteriology, [N.Y.]Cornell 96.
 blood precursors, reliability of arteriovenous differences in, 702.
 bottle, glass, with narrow pouring lip and minimum drip, 705.
Brucella abortus and agglutinins in, relation, 280.
 calculation of fat corrected weight by nomograph chart, 268.
 carotene and vitamin A in, determination, 269.
 cartage in Southwick-Agawam area of Springfield milkshed, Mass. 724.
 catalase activity, effect of sulfanilamide therapy, 702.
 cause of fat variation in, 402.
 centrifuging, physical state of fat and losses in, 101.
 certified, ascorbic acid in, breed and seasonal variations, 270.
 chloride content, 101.
 chocolate-flavored—
 digestibility in vitro, Mass. 562.
 effect of chocolate-flavored sirups on properties, Mass. 562.
 factors to be considered in selecting, Mass. 562.
 nutritive value of sirup containing yeast, Mass. 562.
 coli-aerogenes group in, detection, Pa. 97.
 color, effect of rations, Pa. 97.
 color, improving, 101.
 composite samples, method for more satisfactory analysis, [N.Y.]Cornell 6.
 composition, relation to roughage intake, 703.
 constituents involved in oxidized flavor development, Wis. 97.
 consumption in urban and rural Canada, 437.
 containers, paper, practical aspects of use, 416.
 containers, paper, sanitation of, 706.

Milk—Continued.

- cooked flavor in, Mich. 565.
- coolers, studies, Pa. 115.
- cooling, mechanical, on farms, U.S.D.A. 119.
- cooling on farm by dry type portable cabinet, Nebr. 720.
- curd, digestibility, relation to rate of disappearance from calf's abomasum, 703.
- curd tension, effect of sodium salts, 701.
- digestibility, relation to curd surface, 701.
- distribution and surplus-milk problem, [N.Y.]Cornell 121.
- distribution costs of producer-distributors and subdealers in New Jersey, N.J. 587.
- distribution costs, reducing, 431.
- distribution in Maine markets, Me. 858.
- evaporated, irradiated, stability of vitamin D in, 317.
- evaporated, separation of fat in, 707.
- flavor defects in, preventing, Pa. 97.
- flavor, effect of plane of nutrition, N.Y. State 267.
- flavors, distribution at receiving platform, Mich. 270.
- flush, use for cecal coccidiosis in chickens, West.Wash. 424.
- from Wisconsin, vitamin A in, 83.
- frozen, concentrated, changes occurring in, Pa. 97.
- frozen condensed, properties, factors affecting, 272.
- germicidal properties, Iowa 96.
- goat's and cow's, composition and properties, U.S.D.A. 564.
- goat's, energy value and constituents, 412.
- high grade, production, use of financial stimulus, N.Y.State 888.
- homogenization, low pressure, Pa. 97.
- homogenization, problems, 705.
- homogenizer, sanitary problems in connection with use, 269.
- increasing vitamin content for quality milk, 449.
- industry of New York Metropolitan Area, 436.
- intake, effect on acid-base mineral balances of children, 863.
- irradiation, factors affecting antirachitic response, 268.
- irradiation, improved methods, Wis. 97.
- lactic acid bacteria in, protein metabolism and acid production by, 567.
- lactose content, relation to glucose in arterial blood, 412.
- lipase action in, 413.
- lipolytic activity, [N.Y.]Cornell 96.
- losses in milk plants, N.Y.State 267.
- market, factors affecting supply, Mass. 585.
- marketing in Worcester, Mass. 585.
- marketing, lessons from public control, 290.

Milk—Continued.

- marketing, public regulation in California, 436.
- marketing studies, Ind. 699.
- of goats or cows, sulfanilamide in, 9.
- of various species, ascorbic acid in, effect of ascorbic acid injection and diet, 269.
- off-flavors in, causes, Okla. 96.
- off-flavors in, prevention, Calif. 265.
- oxidized flavor in—
 - and ascorbic acid, 565.
 - and carotene intake, 267.
 - development, relation to vitamin C, lecithin, and carotene, 270.
 - papers, 701.
 - prevention by expulsion of air, 703.
 - relation to titratable acidity, 270.
 - role of carotene and ascorbic acid in feed, 705.
- pasteurization—
 - efficiency, phosphatase test for determining, 414, Pa. 97.
 - for cheese making, 271.
 - status, 268, U.S.D.A. 102.
- pH values, comparison of methods, 8.
- phosphorus in, effect of supplemental phosphorus in ration, Mass. 562.
- physical properties, rate of digestion in vivo, Iowa 95.
- pools, selected types, relative prices to producers under, 436.
- powders, properties, 415.
- processing, factors involved in, [N.Y.] Cornell 96.
- Producers' Association, Falls Cities Co-operative, organization and management, Ky. 130.
- production—
 - effect of artificial light, Mass. 562.
 - effect of complex mineral and vitamin mixtures, Mass. 562.
 - effect of input to output in, Ind. 699.
 - effect of quality of protein in concentrate mixture of ration, [N.Y.]Cornell 96.
 - effect of ultraviolet radiation on, 702.
 - evolution of, 751.
 - of cows and goats, effect of thyroxine, 702.
- products, behavior, relation to physical state of milk fat, 704.
- products in ration and mortality with cecal coccidiosis in chicks, 104.
- products, moisture in, determination, [N.Y.]Cornell 6.
- proportions of consumers' dollar spent for, Wis. 123.
- protein, blood precursors, Mo. 100.
- proteins, biological value in human subjects, 305.
- proteins, biological value in rats, 305.
- rancid, surface tension relation to acid coagulation, 701.
- reduction of methylene blue in, role of bacteria, 567.

Milk—Continued.

- reduction time and keeping quality, relation, 101.
- refrigeration, electric. on farms, Pa 287.
- sampling plunger, folding-type, 414.
- secretion, effect of levels of fat in ration, Mich. 504.
- secretion, endocrinology of, 771.
- secretion, method of study, 702.
- skimmed, *see* Skim milk.
- soft-curd and hard-curd, comparative digestibility, Pa. 97.
- soft-curd, preparation, 701.
- soft-curd types, comparative digestibility in vitro, Pa. 736.
- solids, dry, for baking purposes, 304, Wash. 265.
- solids, dry, water sorption by, 265, 706.
- sugar, utilization, [N.Y.] Cornell 96.
- supply of Rhode Island, sources, R.I. 554.
- test, Babcock, accuracy, effect of lighting conditions, 265.
- total-solids in, determination, [N.Y.] Cornell 6.
- vitamin A in, determination, technic for, 759.
- vitamin A in, effect of feeding alfalfa silage, Wis. 57.
- vitamin C destruction during pasteurization, prevention, 268.
- vitamin C in, determination, 269.
- vitamin D bioassay of, standard methods, 456.
- winter, effect of fodder supplements, 99.
- Milking machines, washing and sterilizing methods, Ind. 699.
- Milkshed, Philadelphia, problems in basic-surplus plan, 437.
- Milksheds, northeastern, surplus problem in, 437.
- Millers, dry, interests of, analysis, Iowa 292.
- Millet—
 - feeding value for turkeys, N.Dak. 561.
 - grains in growing and fattening rations, value, S.Dak. 255.
 - seed disinfection, N.Dak. 225.
 - variety tests, N.Mex. 775.
- Millipedes of economic importance, 69, 809.
- Milo, *Pythium* root rot and development of resistant varieties, Calif. 661.
- Miltogrammatinae and sarcophaginae, natural grouping of species, 809.
- Mineola vacuana*, *see* Cranberry fruitworm.
- Mineral—
 - deficiencies in diet, relation to dental caries, 599.
 - deficiencies in plants, diagnosis, 41.
 - mixed feeds, studies, 8.
 - oil in sprays, wool grease or degrass as substitute for, 238.
 - salts, effect on perosis in chicks, 281.
 - salts, transpiration and absorption, 350.
- Minerals of montmorillonite-beldellite-nontronite type, mechanism of cation exchange in, 174.

Mink—

- breeding, microscopic studies, 358.
- diseases and parasites, treatment, 112.
- farm-raised, anthrax in, 284.
- pelt cycle, effect of shortening daylight periods, 391.
- Minnesota Station, report, 604.
- Mint oil, Ind. 613.
- Miridae—
 - from Texas, new species, 816.
 - toxic effects of feeding by, 380.
- Mississippi College, notes, 606, 890.
- Mississippi Station, notes, 606, 890.

- Mite, air-sac, in fowls in India, 837.
- Mite, red-legged earth, population study in Western Australia, 83.
- Mites—
 - biology, 811.
 - control, progress in, 808.
 - culture, effective control by mechanical exclusion, 637.
 - distribution in the air, U.S.D.A. 673.
 - of subfamily Tarsoneminae of North America, revision, U.S.D.A. 82.
 - on citrus and Persian walnuts, dinitro-*o*-cyclohexylphenol in control, 676.
 - on cotton in Puerto Rico, P.R. 240.
 - relation to animals and plants in South Africa, 824.
 - tarsonemid, control, 809.
 - tropical rat, control, 814.
 - tyroglyphid, in silage and on lily of the valley, 808.
 - tyroglyphid, notes, 69.
- Mohair—
 - fineness, relation to age of animals, Tex. 87.
 - grades and shrinkage, determining, Tex. 87.
- Molasses—
 - blackstrap, for steer fattening rations, Fla. 254.
 - blackstrap, for swine fattening rations, 403.
 - cane, feeding value for hens, Hawaii 638.
 - cane, keeping quality, 758.
 - in combination with oats and corn for hogs, Okla. 85.
- Mold on egg containers in storage at a Chicago plant, 698.
- Moles, trapping, 669.
- Mollusks, teredinid, of South Queensland, 394.
- Molybdenum, copper, zinc, and chromium, comparative nutritive effects, Mass. 477.
- Money management as taught in home economics classes in junior high schools, 800.
- Montesia expansa*—
 - and *Haemonchus contortus* in a young goat, 844.
 - biology, 835.
 - development in intermediate host, 824.
 - life history, 570.
 - pasture infestation with, variation in, 106.
 - variation in, 687.

- Monieziosis of sheep, epizootology, 836.
Monilia candida, heat resistance studies, 764.
Monocrepidius auritus, notes, Ky. 81.
Monophlebus stebbingi, life history and biology, 810.
Montana College, notes, 890.
Montana Station, notes, 160, 890.
Moringa, new cecidomyiad pest of, 811.
Mormonilla vitripennis, finding of hosts by, 241.
Morning-glory, control, Oreg. 35.
Mortgage debts, reduction, Egypt enacts law for, U.S.D.A. 726.
Mosaic virus protein, latent, ultracentrifugal analysis, 524.
Mosaic viruses, properties, Mass. 527.
Mosquito—
eggs, hatching, effect of certain chemicals on, 681.
eggs killed with petroleum oil, 549.
eggs, separating from soil, machine for, U.S.D.A. 241.
Extermination Association, New Jersey, meeting, papers, 681.
Extermination Commission of Suffolk County, New York, report, 682.
larvicide and fertilizer combined, ammonium sulfate as, 682.
larvicide, New Jersey pyrethrum, use, N.J. 549.
traps, comparative results obtained by, 549.
Mosquitoes—*see also* Anopheles, Malaria, and Yellow fever.
associated with bromeliads, P.R.Col. 235.
breeding, design of flushing siphon for control, 681.
breeding in Florida salt-water marshes, experimental diking for control, 549.
British, morphology, biology, and control, 78.
control and wildlife conservation, coordination, U.S.D.A. 668.
control, conservation and ecological aspects, 549.
control, effect of terracing and pond-making, Okla. 68.
in North Dakota, survey, N.Dak. 548.
new larvicide for, 398.
new records from Key West, Fla. 670.
of Ethiopian region, 548.
of Owens Valley, California, 681.
of Southeastern States, U.S.D.A. 819.
relation to encephalomyelitis, equine, 807.
rice field, biologies, Ark. 548.
salivary and stomach secretion of, 398.
studies, Del. 238.
transmission of lymphocytic choriomeningitis by, 571.
Moths, chalcidoid parasites on, 810.
Motor fuel consumption and tax receipts, State, U.S.D.A. 851.
Mower adjustment, Miss. 850.
Muck crop diseases in New York, U.S.D.A. 655.
Mulberry popcorn disease, U.S.D.A. 655.

Mules, work, feeding practices, Miss. 625.
Murgantia histrionica, *see* Harlequin bug.
Musca domestica, *see* Housefly.
Muscidifurax raptor, notes, P.R. 250.
Muscle-coenurosis of sheep, 836.
Muscles, dystrophy, dietary factors associated with, 89.
Muscular dystrophy, nutritional, effect of vitamin B, 557.
Muscular fatigue, effect of gelatin on, 306.
Mushrooms—
casing soil, relation to yield, U.S.D.A. 514.
culture, Pa. 40.
damping-off, relation to *Fusarium* spp., 664.
fungus diseases, control, Pa. 50.
insect and pests, 508.
pests, 69, Pa. 68.
Muskgrass as duck food, U.S.D.A. 538.
Muskmelon—
downy mildew, control, S.C. 50.
downy mildew resistant variety, Fla. 221.
quill, *Pythium* root rot of, 531.
Superb Golden, a new hybrid, Mich. 211.
Muskmelons—
breeding, N.Y.State 211.
commercial fertilizer v. manure for, Iowa 40.
effect of copper sprays, Conn.[New Haven] 526.
sprays for, Mass. 526.
varieties, Iowa 40.
varieties and fertilization, S.C. 41.
variety tests, Wis. 512.
Muskrate—
biology and economic importance in western Europe, 391.
ecology, Iowa 65.
in central Wisconsin, 804.
production, effect of ditching, Del. 238.
reaction to drought, 669.
Mustard—
family, species in North Dakota, N.Dak. 604.
greens, available iron in, 596.
Mutation, new dwarf, in rats, 193.
Mutillids, photopoid, collected by Dr. K. A. Salman in California, 553.
Mycetes, Portuguese, 892.
Mycobacterium—
lower limits of genus, relation to *Proactinomyces*, 621.
paratuberculosis emulsified with paraffin oil, infection of laboratory animals with, 572.
paratuberculosis enteritis, viability, 837.
tuberculosis avium, biologic characteristics, 286.
Mycology, industrial, textbook, 19.
Mycorrhizal fungi, saprophytes or parasites, 487.

- Myrorhizas**—
in agriculture, need for study, 764.
occurrence and extent of knowledge concerning, 19.
- Mycosphaerella**—
berkeleyi, development, 524.
disease of winter pear, Ala. 59.
fragariae, mode of action of bordeaux on, La. 656.
fragariae, notes, Oreg. 61.
fragariae, notes, 536.
grossulariae leaf spot, notes, 232.
leaf spots of peanut, control, 334.
undescribed species, mode of action of bordeaux on, La. 656.
- Myelin degeneration**, polarized light method for study compared with others, 877.
- Myriophis**, control on dates, constant temperature hot air sterilizer for, 503.
- Myiasis**—
in domestic animals, new prophylaxis for, 710.
in domestic animals, prevention and treatment, 710.
pH of exudates of wounds, relation to oviposition stimulus of screwworms, 418.
- Myrmelachista ramulorum** in coffee groves, poison bait for, P.R. Col. 541.
- Myxomatosis**, infectious, of rabbits, 707.
- Mycocallis meridionalis** n.sp. on oak leaves, 817.
- Myzus convolvuli**, notes, 670.
- Myzus persicae**, see Peach aphid, green.
- Myzus pseudosolanii**, notes, 816.
- Nemophyllaria**, new taxonomy in genus, 52.
- β -Naphthoxyacetic acid**, new growth substance, 769.
- Napier grass**—
breeding, Fla. 200.
cutting and strain tests, Hawaii 638.
value for pastures, Fla. 201, 254.
- Narcissus**—
bulb pests, vapor heat treatment for, U.S.D.A. 674.
diseases, [N.Y.] Cornell 40.
mosaic, studies, [N.Y.] Cornell 667.
mosaic virus, transmission by aphids, 670.
- Nasutitermes costalis** in Puerto Rico, P. R. Col. 244.
- National**—
Formulary, staining solutions included in, 184.
trust as landlords, 481.
- Nationality groups**, Wis. 132.
- Naupactus leucoloma**—
biology, U.S.D.A. 242.
serious threat to southern agriculture, 822.
- Nebraska Station**, notes, 160.
- Nebraska Station**, report, 731.
- Nectar flow**, period and rate in an experimental apiary, Okla. 68.
- Nectria** cankers of New England hardwoods, avenues of entrance, 63.
- Negro**—
population, sickness and medical care in delta area, Ark. 447.
press, race consciousness as reflected in, 297.
- Negroes, American**, possibility of distinctive culture contribution from, 136.
- Nematocides**, new, and factors governing efficacy, 106.
- Nematoda**, revised classification, 835.
- Nematode**—
eggs in sheep feces, new technic for counting, 715.
meadow, biology, 234.
new, of cattle, 836.
unrecorded filarid, of horses, 837.
- Nematodes**—see also Root knot nematode.
attractiveness of roots and excised shoot tissues to, 537.
bursate, control of free-living stages, 571.
bursate, of horses and sheep, Blomonica and control, 711.
control on chrysanthemums, Conn. [New Haven] 526.
control with chloropicrin, 224.
in tomato greenhouses, control, R.I. 795.
new, from peafowl, 810.
new, from rodents, 570.
on ginger rhizomes from Peru, 535.
or other animals which feed on decomposing organic matter, suitable terms for, 835.
predaceous, from Hawaii, 234.
varietal resistance of potatoes to, 530.
- Nematus abietinus**, notes, 401.
- Neoborus** n.sp., description, 816.
- Neocatolaccus indicus** n.sp., description, 401.
- Neocephalobus peruvensis** n.sp. on ginger rhizomes, 535.
- Neodiprion pinetum**, control, Mich. 253.
- Neoplastic**—
and neoplasticlike diseases, Mass. 569.
disease in poultry, Oreg. 103.
- Nephotettix bipunctatus cincticeps**—
notes, 75.
on rice in Japan, 545.
- Netella**, Nearctic species, 82.
- Netellini**, revision of genera, 82.
- Neurolymphomatosis** in poultry, 837.
- New Jersey Station**, notes, 320, 606.
- New Mexico College**, notes, 891.
- New Mexico Station**, notes, 891.
- New Mexico Station**, report, 837.
- New York Cornell Station**, notes, 463.
- New York Cornell Station**, report, 157.
- New York State Station**, notes, 463, 606.
- New York State Station**, report, 819.
- Newspapers**, Washington country weekly, distribution and characteristics, Wash. 589.
- Nesara viridula**, see Stinkbug, southern green.
- Nicotiana**—
sandwiae and sterile hybrid, induction of tetraploidy with colchicine, 190.
tabacum macrophylla, heritable variations induced by abnormal temperatures, 495.
virus 6 protein, purification, 55.

- Nicotinamide treatment of pellagra, 601.
- Nicotine-bentonite-soyoll, tank-mix, large-scale tests, 819.
- Nicotine-bentonite spray—
experience with, 818.
residue removal from apples, 818.
- Nicotine—
effect on rats, 235.
sprays, agar-agar as new activator for, 677.
- Nicotinic acid—
as therapeutic agent, review, 459.
deficiency in dogs and pigs, effect on cozymase content of tissues, 877.
failure to prevent nutritional cytopenia in monkeys, 459.
growth factor for pea seedlings, 23.
in swine nutrition, 693.
ineffectiveness as cure for chick pellagra, Wis. 87.
nutritional significance, 877.
use in culture of excised plant parts, 180.
- Night blindness treated with vitamin A, 311.
- Nilaparvata oryzae* on rice in Japan, 545.
- Nippostrongylus muris*, passive immunity to, effect of dosage and interval after infection, 106.
- Nitrates—
assimilation, R.I. 760.
determination, phenoldisulfonic acid method, 472.
soil, optimum levels, R.I. 760.
- Nitrification, Tex. 14.
- Nitrification in soil, effect of chloropicrin treatment, R.I. 760.
- Nitrogen—
fixation, biological, mechanism, 691.
fixation in soils, Pa. 14.
fixing powers of soil, effect of cropping, 342.
in soil, studies, Hawaii, 617.
in soils under several cropping systems, accretion, [N.Y.] Cornell 13.
in various forms, leaching studies, 176.
losses by leaching, lysimeter studies, Ala. 13.
metabolism on low-protein and on medium-protein diet, 595.
mineralizable, in Hawaiian soils, 342.
of urea and ammonium bicarbonate, utilization by calves, 403.
removal by cropping and drainage from lysimeters, Ky. 476.
role in fungus thermogenesis, 352.
starvation, Wis. 521.
transformation in soil, sunlight as factor, 342.
- Notonota punctatella*, see Rose leaf beetle.
- Nodular worms, removal from swine, efficacy of phenothiazine for, 105.
- Nolana texana*, poisonous to livestock, Tex. 104.
- Nomadaoris septemfasciata*—
in Union of South Africa, 815.
notes, 394.
- Nomenclature, binomial system, proposed extension to include viruses, 222.
- North Dakota College, notes, 891.
- North Dakota Station, notes, 463, 752, 891.
- Nosema carposcopae*, life cycle, 82.
- Nothopneus*—
fasciipennis, notes, 401.
hemipterus, biology and control, 552.
- Notocella uddmanniana*, notes, 509.
- Nun moth and parasites, biology, 396.
- Nursery—
cultural practices, conservation, Iowa 40.
diseases, studies, Oreg. 50.
stock, cold resistance in, nature, Nebr. 623.
stock inspection and shipment, law and regulations in Connecticut, Conn. [New Haven] 157.
stock, inspection, certification, and transportation, Ky. 787.
stock transportation in United States and Canada, regulations, Conn. [New Haven] 157.
- Nut casebearer, control, Fla. 238.
- Nut trees, irrigation, Calif. 210.
- Nutgrass—
control, Tex. 37.
control with chloropicrin, 374.
life history, Ala. 33.
- Nutrient media, see Culture media.
- Nutrients, essential, effect of deficiencies in, Pa. 86.
- Nutrition—see also Diet.
and physical training in Great Britain, 734.
animal, see Animal nutrition.
clinical assessment, 745.
cobalt in, 405.
human, relation to social and economic life of South, 861.
improved in the South, adjustments needed for, 861.
mineral elements in, 608.
of Union of South African population, 594.
plant—see also Plant nutrition.
animal and human, and soils, interrelation, 486.
policies, national, survey, 593.
problems in Great Britain, 734.
research program at the experiment station, relation to State problems, N. Dak. 595.
Technical Commission on, report, 865.
- Nuts, surplus, other uses for, Calif. 185.
- Nuts, varieties, West. Wash. 374.
- Nuttall, G. H. F., biographical sketch, 803.
- Nylon, identification, 155.
- Nymphula depunctella*, life history, habits, and control, 817.
- Oak—
coppice stands, persistence of stems per sprout clump, 218.
cuttings, growth-promoting substances for, Tex. 41.
heart rot, causal fungus, 360.

Oak—Continued.
 root fungus, soil injections of CS_2 for, Calif. 220.
 trees, dying, Wis. 527.

Oaks—
 breeding, Tex. 41.
 chromosome structure, Tex. 41.

Oat—
 and pea silage, *see* Silage.
 black rust, control, barberry eradication for, Pa. 50.
 coleoptile—
 effect of various compounds upon straight growth, 767.
 epidermal cells, membranes of, 346
 growth and cell structure in first internode, effect of radiation, 180.
 peptidase activity in, 182.
 structure of cell wall during growth, 180.
 crown rust, early appearance in Arkansas, U.S.D.A. 378.
 disease-resistant strains, development, Iowa 48.
 diseases, seed-borne, control, Iowa 48, N.Y.State 222.
 downy mildew, U.S.D.A. 655.
 flour for preventing rancidity in butter, Okla. 96.
 hay and oat straw, poisonous, Wyo. 569.
 hay poisoning, 416, 559.
 mill feed, use and value in livestock rations, Wis. 89, 90.
 nematodes on winter wheat, 798.
 seed disinfection, N.Dak. 225.
 seed, field inspection for, Miss. 774.
 seed, weed seeds found in, N.Y.State 787.
 smuts, Wash. 222.
 smuts, physiologic races and inheritance of resistance in hybrids to, 526.
 smuts, rusts, and minor diseases, parasitism of, Iowa 48.

Oats—
 adaptation studies, Nebr. 363.
 Bannock, new variety, Idaho 638.
 breeding, Fla. 200, Ga.Coastal Plain 363, Idaho 638, Iowa 33, Nebr. 639, N.Y. Cornell 34, Pa. 35, S.Dak. 201, Tex 37, Wash. 201, Wis. 502.
 crosses, inheritance in, Minn. 634.
 culture experiments, Ga.Coastal Plain 363, Nebr. 363, Okla. 35, Tex. 37, Wash. 201, Wyo. 503.
 digestion coefficients for dairy cows, effect of fineness of grinding, 708.
 drill surveys, N.Y.State 209.
 early and late planting, yield response to, Iowa 121.
 factors in affecting growth and feathering in fowls, Iowa 84.
 fertilizer experiments, Fla. 200, Ga. Coastal Plain 363, Tex. 37.
 genetic studies, [N.Y.]Cornell 34.
 in turkey rations, S. Dak. 255.
 prices, index number, N.Dak. 131.
 production, changes in technology and labor requirements, 586.

Oats—Continued.
 sheaf, feeding to lambing ewes, fatal effect, 559.
 smut-free, yield, effect of seed treatment, Ind. 655.
 species, annual and perennial, cross-pollination, 356.
 surface v. furrow drilling, Nebr. 640.
 v. spelt for pigs, Mich. 560.
 varieties, outstanding, Wis. 502
 variety tests, Alaska 362, Fla. 200, Ga. Coastal Plain 363, Idaho 638, Ind. 773, Iowa 33, La. 363, Nebr. 363, 639, N.Mex. 775, Pa. 35, S.C. 36, S.Dak. 201, Tex. 36, Wash. 201, Wyo. 503.
 Victoria, albino seedlings in, 356.
 whole, value in laying rations, S.C. 86.
 yield and land valuation, Iowa 345.
 yield, effect of different seed treatments, Ind. 638.
 yield, relation to nitrogen application, Miss. 774.

Oberlea dimaculata, *see* Raspberry cane borers.

Oedaleus australis, notes, 244.

Oestradiol monobenzoate and oestrone, relative potencies, 361.

Oestrin, effect on ovariectomized rats, 199.

Oestrogen—
 assay, method, 198.
 crystalline concentrate, isolation from urine of pregnant mares, 198.
 effect of massive doses on ova transport in ovariectomized mice, 198.
 injections, effect on lactogen in pituitary glands of ovariectomized rats, 31.
 injections into cocks, effect, 637.
 injections into pigeons, effect on calcium in blood and bones, 637.

Oestrogenic—
 activity, mechanism, analysis, 198.
 hormones and diethylstilboestrol, difference of effect, 199.

Oestrone—
 and oestradiol monobenzoate, relative potencies, 361.
 response of mammary gland of monkey to, 195.
 sulfate, isolation from urine of pregnant mares, 198.

Oestrous cycle—
 effect of inanition, 773.
 in mice, effect of choline chloride on, 32.

Oestrus ovis, *see* Botfly, sheep.

Office of Experiment Stations, notes, 607.

Ohio Station, notes, 606, 891.

Oil—
 emulsions, effects of pH upon deposit of oil and water phases, 242.
 in water emulsions, microscopic technique for study, 701.
 plants in the Crimea, pests of, 392.
 press-cake meals, vitamin G in, 557.
 property taxation, relation to farm taxes in Kansas, Kans. 291.

Oil—Continued.

sledge, acid, insecticidal action on mosquito larvae, 399.

spray deposits, factors affecting, 243.
sprays for control of rosy apple aphid, Conn.[New Haven] 540.

sprays, mineral, for insecticides, Wash. 289.

Oils—see also Fats and specific oils.

and fats, production and international trade, 727.

feeding to dairy cows, effect, 98.

mineral, as insecticides, 543.

summer, 542.

use for calf feeding, 703.

Oklahoma College, notes, 606.

Oklahoma Station, notes, 606

Oklahoma Station, report, 157.

Okra, spineless, breeding, S.C. 41.

Old age assistance—

characteristics of persons receiving Iowa 132.

in the South, demographic basis of, 731

Oleander—

breeding, Tex. 41.

witches'-broom disease, Fla. 221.

Olignonchus ulmi, control, 401.

Olive—

diseases on New York market, U.S.D.A. 48.

products, Calif. 165.

Omphalia spp., affecting dates, Calif. 220.*Onchocerca cervicalis*, notes, 837.

Onion—

blast disease, Mass. 526.

diseases, Iowa 48, U.S.D.A. 794.

diseases on New York market, U.S.D.A. 48.

downy mildew, varietal resistance, R.I. 795.

fields, winter cover crops for, Mass. 512.

insects, biology and control, Iowa 65.

juice, relation to bacterial growth, Mass. 591.

maggot, Oreg. 68.

maggot, life history, habits, and control, 399.

mildew, control, [N.Y.]Cornell 49, Oreg. 50.

mildew, spraying for, Calif. 220.

pink root disease, 526.

pink root, host parasite relations, 532.

roots, invasion by *Phoma terrestris*, 526.

seed, longevity, relation to storage conditions, U.S.D.A. 212.

smut and downy mildew in muck crop areas, U.S.D.A. 525.

smut, control, [N.Y.]Cornell 49, U.S.D.A. 655.

strains resistant to downy mildew and to pink root, development, Calif. 220.

thrips, biology and control, [N.Y.]Cornell 66.

thrips, biology, habits, and distribution, Calif. 245.

thrips, control, Mass. 540.

Onion—Continued.

thrips damage to greenhouse carnations, reducing, Wash. 239.

thrips, notes, Conn.[New Haven] 540.
Fla. 238, Tex. 67.

yellow dwarf in Iowa, Iowa 49.

Onions—

breeding, Calif. 209.

carbohydrates of, effect of storage and processing, Mass. 512.

household storage, 503.

quality and yield, Tex. 41.

seed, production, factors affecting, Calif. 645.

variety tests, Pa. 374.

weeds in, control by herbicides, [N.Y.] Cornell 34.

White Grano, effects of irrigation, N.Mex. 787.

wind injury to, U.S.D.A. 655.

yield tests, Nebr. 645.

Onthophagus incertus, notes, P.R. 250.*Oospora citrauranti* and *Penicillium digitatum*, synergism in, 232.*Ophiobolus graminis*—

infestation of soil by, spread, 47, 381.

prevalence, effect of climatic conditions 47.

Ophthalmia—

in horses, transmission experiments, Ky. 569.

verminous, in equines, 837.

Ophi, whole fresh, vitamins in, Hawaii 736

Opsotheresia n.sp., notes, 820.

Orange—

diseases on New York market, U.S.D.A. 48.

groves, late, costs and returns, Fla. 290.

juice, fermentation, effect of addition of nitrogenous nutrients, 331.

juice, microbiological analyses, Fla. 301.

juices and pulps, preservation, Fla. 165.

peel and pulp meal, value for poultry, Calif. 254.

tortrix, dusts for, Calif. 238.

tortrix, notes, 818, Fla. 238.

tortrix, pest of citrus, 547.

tortrix, toxicity of dinitro-*s*-cyclohexyl-phenol to, 676.

trees, Satsuma, effect of oils on, Ala. 65.

Oranges—

composition, rootstock effect, 518.

Navel, effect of arsenic and copper sprays, 815.

pineapple, pitting and decay in, 62.

quality, effect of lead arsenate and copper carbonate sprays, 216.

Satsuma, fertilizer for, La. 645.

Valencia, granulation, Calif. 220.

Orchard—

cover crops—

notes, Wash. 211.

tolerance to arsenical toxicity in soil, 214.

grass, nurseries for improvement, West. Wash. 363.

Orchard—Continued.

- heaters and heating technics. improvement, Calif. 210.
 heating problems, Calif. 287.
 insects in Tsingtao, 393.
 pests, 392.
 soils in Pennsylvania, potassium availability, 483.
 soils, seasonal variation of oxygen and carbon dioxide in, 647.
 spraying in spring, Miss. 787.
 surveys, data from, 671.
 trees, cultural requirements. Nebr. 645.
 trees, development of wound tissue, effect of growth substances, 347.
 trees, protecting from deer, U.S.D.A. 668.
- Orchards—see also Fruits, Apples, Peaches, etc.
 establishment, Mo. 515.
 fertilization and irrigation, Wash. 211.
 heating, Tex. 41.
 irrigation, Nebr. 645.

- infectious bulbar, monograph, 423.

- range, etiology and transmission in poultry, Iowa 103.

Paramphistomum skrjabini from rumen of cattle and buffaloes, 836.*Paraphoranthia politana* n.sp., description, 251.*Parasetigena silvestris* (segregata), notes, 396.

Parasite fauna of Hawaii, 570.

Parasites—

- animal, in Puerto Rico, check list, P.R. 275.
- animal, in Sweden, 838.
- gastrointestinal, of ruminants, new system of anthelmintic control, 714.
- insect, host finding by, 241.
- international control, 835.
- of blood of wild birds, 579.

Parasitism, age resistance of animals to and goblet cells, 838.

Paratetranychus—

- citri*, see Red mite, citrus.
- pilosus*, see Red mite, European.

Paratheresia spp., introduction in Louisiana, 684.*Paratrechina longicornis*, notes, 807.*Paratiroa cockerelli*—

- breeding areas, 237.
- effect of temperature, 246.
- notes, 670, Tex. 67.

Paratuberculosis, see Johne's disease.

Paratyphoid—

- and trichomonas infection in pigeons, 286.

Paratyphoid—Continued.

- bacilli, studies, Ky. 569.
- disease in pigs, outbreaks in Ireland, 845.

- of chicks and poultry, Calif. 273.

Pareuderus toymotus, egg parasite of amaranthus borer, 811.*Paropsis dilatata*, notes, 72.

Parthenocarp, natural, cause, 180, 348.

Partridges in Great Britain, food of, 241.

Parturition, inhibition in rabbit by injection of oestrogenic hormone, 360.

Paspalum spp., ergot of, 56, Hawaii 653.*Pasteurella tularensis*, nonfatal infection, in snowshoe hare, 834.

Pasteurization—see also Milk.

- efficiency of dairy byproducts, rapid phosphatase test for, 704.
- high temperature, laboratory equipment for, 702.

Pasture—

- areas, vegetational survey, Hawaii 638.
- contour machine, improved, Iowa 115.
- grasses, see Grasses.
- herbage, phosphorus in, Ky. 501.
- mixtures, variety tests, Idaho 638.
- plants, root development and deterioration, Fla. 200.
- plants, studies, Nebr. 363.
- returns, methods of measuring, Wash. 265.

Pastures—see also Grasses, Grassland, and Meadows.

- basin method of treating to prevent erosion, Iowa 115.
- beef-producing capacities, effect of phosphorus fertilizers, S.C. 86.
- carpet grass, establishing and maintaining lespedeza and white clover in, S.C. 36.
- effect of fertilizers, Fla. 200.
- fertilizer experiments, Idaho 638, Ind. 773, La. 691, 700; Tex. 37.
- for beef cattle on rice lands, improving, La. 558.
- improvement, Fla. 200, Iowa 34, La. 639, Me. 34, Nebr. 640, Tex. 14, 37, 203.
- in Texas forest region, mineral and protein deficiencies, Tex. 87.
- irrigated, fertilization, 264.
- management, Miss. 774.
- nutritive value, 60.
- on logged-off land, studies, West. Wash. 363.
- permanent, methods of establishing, Fla. 201.
- response to fertilizers, La. 688.
- returns, effect of fertilization, Pa. 97.
- rotational system of grazing, S.C. 97.
- seeding grasses and legumes for, N.Dak. 201.
- soil conditions and plant growth on, effects of fertilizers and grazing, Iowa 34.
- strongyloid larvae in, bionomics and duration of infection, 278.

Pastures—Continued.

- studies, 404, Alaska 362, Conn.[New Haven] 476, Fla. 200, Ga.Coastal Plain 404, Ky. 501, La. 639, Mass. 501, Wyo. 503.
- studies on peat and muck soils, Fla. 201.
- sugarcane silage and shocked sugarcane, for wintering cattle, comparison, Fla. 254.
- supplementary, comparison of Sudan grass, millet, oats, and winter rye for, R.I. 775.
- supplements for long grazing, Miss. 774.
- survival of worm parasite infection on, 571.
- unimproved and improved, carrying capacity, Tex. 87.
- vegetational changes as result of turrowing, 777.
- year-round grazing on succession of annual crops in North Carolina, 257.
- yields and consumption under grazing conditions, 777.
- yields as measured by clip plots and by grazing, 703.

Pea—

- and oat silage, *see* Silage, oat and pea.
- aphid—
 - control, 671, 679, Fla. 238, N.Y. State, 239, Wis. 541.
 - control, element of timing, 543, 817.
 - effect of alfalfa, Wash. 239.
 - injury to clover, experiments with resistant strains, Ky. 540.
 - insecticides, time of application, Wis. 541.
 - on alfalfa and canning peas, 807.
 - studies, Me. 67, Oreg. 68, Tex. 67.
- cuttings, rooting experiments, 180.
- damping-off, control, N.Y.State 222.
- disease resistant varieties, 393.
- diseases on New York market, U.S.D.A. 48.
- diseases, seed borne, control, N.Y.State 222.
- diseases, virus, Wash. 222.
- downy and powdery mildews, Wash. 222.
- downy mildew, Fla. 222.
- embryos, isolated, growth, effect of nicotinic acid, 23.
- mildews, downy and powdery, Oreg. 50.
- mosaic, Oreg. 50.
- near-wilt, seed transmission of, Idaho 655.
- roots, isolated, meristematic activity, relation to vitamin B₁, 767.
- roots, isolated, nicotinic acid as growth factor for, 182.
- roots, isolated, synthesis of vitamin B₁ by, 23.
- seed and seedling rots, Fla. 221.
- seed treatment, Wyo. 527.
- seed treatments, relation to germination, 220.
- vine, red-stemmed, poisonous to live stock, Tex. 104.

Pea—Continued.

- weevil, biology and control, 253.
- weevil, control, N.Y.State 239.
- weevil control, dust and trap crops for, Idaho 671.
- weevil, distribution in Northwest, 808.
- weevil, notes, Oreg. 68.
- wilt, Oreg. 50.

Peach—

- aphid, green—
 - inhibition of virus activity by, 52.
 - on potatoes, 816.
 - transmission of *Hyoscyamus* virus 3 by, effect of fasting, 75.
 - aphid, vector of virus diseases, Me. 49.
 - bacterial spot, U.S.D.A. 525.
 - bacterial spot, recent advances in knowledge, 533.
 - borer, control, 671, Ohio 515.
 - borer control with ethylene dichloride, 239, 806, 819.
 - borer, note, Tex. 66.
 - brown rot in transit and storage, 533.
 - cuttings, growth-promoting substances for, Tex. 41.
 - diseases, U.S.D.A. 378.
 - diseases, obscure, in Idaho, U.S.D.A. 655.
 - diseases, spraying problems for control, 532.
 - insects, control, N.Y.State 239.
 - leaf curl, U.S.D.A. 378, 525, 795.
 - mosaic control, 533.
 - mosaic, early history and present data, 387.
 - mosaic, host relation studies, 47.
 - mosaic in Colorado, control, 47.
 - mosaic, Maynard plums as carriers, 47.
 - moth, yellow, on papaw, 393.
 - orchards, soil management in, Pa. 40.
 - phony disease, Ky. 526.
 - powdery mildew, 63.
 - red suture disease, U.S.D.A. 795.
 - scab, U.S.D.A. 378.
 - scale, West Indian, control, P.R.Col. 541.
 - tree's, death of, U.S.D.A. 525.
 - trees in Wenatchee-Okanogan District, Wash. 587.
 - viroses in Massachusetts, U.S.D.A. 795.
 - X disease, Conn.[New Haven] 157, 526, U.S.D.A. 655.
 - X or yellow-rind virosis disease, N.J. 61.
 - yellow and little peach, dissemination, Del. 221.
- Peaches—
- boron injury to, Calif. 220.
 - breeding, Tex. 41.
 - breeding for mosaic and delayed foliation resistance, Calif. 220.
 - canned clingstone, annual average f. o. b. prices, Calif. 727.
 - Elberta, nitrogen fertilization in Sandhills, N.C. 375.
 - fall fertilization in Sandhills, N.C. 375.
 - fertilizers and cover crops for, S.C. 41.
 - frost injury in Delaware, U.S.D.A. 378.
 - genetic composition, Mass. 512.

Peaches—Continued.

- hardy, species crosses to develop, Iowa 40.
- hardy varieties, 650.
- industry in western New York, [N.Y.] Cornell 128.
- malnutrition in, symptoms, 800.
- precooling rail shipments and use of ventilated packages, Ill. 650.
- production in Illinois, relation to temperature, 649.
- tests with dormant oil containing dinitro-cyclohexyphenol on, 806.
- thinning, N.Y.State 791.
- varieties, Ind. 645, La. 645, S.C. 41.
- varieties for home orchards, Miss. 787.
- variety tests, Ga.Coastal Plain 374.

Pekeska sp., notes, 244.

Peanut—

- hay as roughage for fattening steers and wintering cows, Ala. 84.
- hulls, rate of decomposition, Mass. 477.
- leaf spot, control, 384.
- meal, deficiencies, Fla. 255.
- seed stock, parasitic fungi harbored by, 795.
- vines, dusting sulfur on, Tex. 37.

Peanuts—

- breeding, Fla. 200, Ga.Coastal Plain 363, Tex. 37.
- culture experiments, Fla. 200, Ga.Coastal Plain 363.
- fertilizer experiments, Fla. 200, Ga.Coastal Plain 363, N.C. 39.
- rotating with crotalaria and native cover crops, Fla. 200.
- runner, hogging off, returns from, Ga.Coastal Plain 404.
- Spanish, dusting with sulfur, Ga. 529.
- supplemental value for chicks and laying hens, Ala. 84.
- variety tests, Fla. 200, Ga.Coastal Plain 363, Tex. 36.
- yield, effect of foliage dusts, Tex. 51.

Pear—

- bitter pit and related diseases, Wash. 222.
- blight injury, U.S.D.A. 378.
- blight-resistant stocks, tests, Calif. 210.
- diseases on New York market, U.S.D.A. 48.
- fire blight, [N.Y.]Cornell 49.
- fire blight resistant variety, Pa. 50.
- flowers, structure, [N.Y.]Cornell 43.
- leaf blister mite, Calif. 238.
- leaf blister mite, bud form, biology and control, 253.
- rootstocks from seed, 517.
- rots, Wash. 222.
- scab in New York, U.S.D.A. 378.
- seeds, germinating methods, 517.
- stony pit, a transmissible disease, 60.
- thrips, biology, habits, and distribution, Calif. 245.
- thrips, control, 401.
- thrips on prunes, 239.

Pear—Continued.

- trees, dying, associated with *Dothiorella* sp., La. 656.
- trees in Wenatchee-Okanogan District, Wash. 587.
- trees, insects affecting, 393.
- trees, seedling, variation in, 517.

Pears—

- boron injury to, Calif. 220.
- breeding, Iowa 40.
- ethylene evolved by, determination, 215.
- pollination, 215.
- Pontotoc, for home orchards, Miss. 787.
- Portuguese, bud mutations in, 892.
- ripening, effect of ethylene on, 518.
- Williams, codling moth injury, control, 76, 77.

Peas—

- Alaska and sweet types, for canning in Maryland, Md. 790.
- Alaska, forecasting maturity grades by use of tenderometer, 515.
- Austrian winter, rotations under Everglades conditions, Fla. 200.
- blackeyed, available iron in, 596.
- breeding for resistance to near-wilt in, Wis. 527.
- canning—

- aphids on, time of fumigation and subsequent resistance, 246.
- calcium-phosphorus ratio of skins, relation to maturity, 473.
- in Wisconsin, Wis. 790.
- practicability of seed treatment, Wis. 527.
- root rot, fertilizer in control, Wis. 527.
- varietal and cultural experiments, Wis. 513.
- varieties, propagation, Alaska 374.
- yield, increase by insecticides, Wis. 541.
- costs, expenses, and returns from, Miss. 854.
- cull, in cattle feeding rations, value, Wash. 255.
- fertilization, Miss. 788.
- fertilizer experiments, Calif. 199.
- fertilizer requirements, P.R.Col. 512, Wis. 512.
- flat, analysis at different stages of development, West.Wash. 363.
- freezing, fertilizers for, West.Wash. 336.
- frosted, losses of vitamin C during freezing, defrosting, and cooking, 146.
- frozen-pack, cooking quality, factors affecting, Wash. 301.
- frozen-pack, vitamin C in, Wash. 301.
- frozen-pack, vitamin values, 313.
- hard seed in, N.Y.State 209.
- harvesting equipment for, Idaho, 719.
- laboratory germination, elimination of saprophytes during, 383.
- moisture usage by, Wash. 201.
- planting methods, Miss. 788.
- seed treatment for, Tex. 51.
- spraying and dusting, Fla. 221.

Peas—Continued.

- transplantation experiments, 767.
- varieties and fertilization, S.C. 41.
- varieties suitable for frozen storage, 865.
- variety and strain tests, Pa. 40.
- variety tests, P.R.Col. 512, Pa. 374, Wyo. 503.
- winter, *Mycosphaerella* disease of, Ala. 58.
- winter, variety tests, Tex. 37.

Peat—

- bog, experimental, low temperatures, meteorological phenomena affecting, 334.
- bogs, marsh gas in ecology of, 486.
- soils, neutralization curves for humic acids of, [N.Y.]Cornell 344.
- soils, subsidence, Fla. 287.

Pecan—

- bark grafting, Miss. 787.
- cuttings and roots, treatment with root-inducing chemicals, 519.
- groves, management, Okla. 40.
- insects, Tex. 66.
- scab and foliage diseases, control, U.S. D.A. 388.
- trees headed to various degrees of severity in top working, root composition and top development, 653.
- trees, young, effect of growth-promoting substances, Okla. 40.

Pecans—

- culture, fertilizers, and handling, Fla. 210.
- experiments at Everglades Substation, Fla. 210.
- food storage, growth, and reproduction, relation to N absorption, Fla. 210.
- fruit development, prefilling period, 653.
- varieties, La. 645, N.Mex. 787, Okla. 40.
- variety tests, La. 645.

Pectin—

- and pectin-sugar solutions, viscosity or plasticity as index to jelly formation, Del. 165.
- solutions, dilute, viscosity, effect of metallic salts and pH, Del. 471.

Pectinophora gossypiella, see Bollworm, pink.
Pedicularis graminum, nuclear cytology, 464.

Pellagra—

- chick, ineffectiveness of nicotinic acid as cure for, Wis. 87.
- niotinamide treatment, 601.
- nicotinic acid in treatment, 458.
- nutritional significance of nicotinic acid in, 877.
- producing diet, effect on Herbivora, 406.

Pemphres affinis—

- distribution, food plants, and original home and habitat, 206.
- parasites of, 401, 686.

Penicillium—

- digitatum* and *Oospora citricaurantii*, synergism in, 282.
- injury of corn seedlings, soil factors in, 54.

Penicillium—Continued.

- roqueforti*, fat and protein metabolism, Iowa 96.
- roqueforti* strains, gas requirements, 702, Wash. 265.
- sp., destruction of salicylic aldehyde in soil by, 226, 660.
- Pennsylvania College, notes, 160.
- Pennsylvania Station, notes, 160.
- Pennsylvania Station, report, 157.
- Pentatrachomonas* sp., cultures from livers of fowls, 104.
- Pentobarbital sodium, narcotics and anesthesia in swine produced by, 111.
- Pentosans and pentoses, detection, identification, and gravimetric determination, 473.
- Peonies, grading and marketing, Ind. 645.
- Peony blooms, preservation, Oreg. 41.
- Pepper—
 - diseases on New York market, U.S.D.A. 48.
 - Verticillium* wilt, 56.
 - weevil, Fla. 238.
- Peppergrass, perennial, in North Dakota, N.Dak. 35.
- Peppermint—
 - anthracnose control, Ind. 655.
 - culture, costs, labor requirements, and returns from, Ind. 721.
- Peppers—
 - breeding, Conn.[New Haven] 512.
 - chile, varieties, N.Mex. 787.
 - culture, Mass. 512.
 - damping-off, seed and soil treatments for, 654.
 - fertilizer and lime requirements, La. 645.
 - fertilizer requirements, P.R.Col. 512.
 - induced parthenocarp of, 492, 513.
 - variety and strain tests, Pa. 40.
 - variety tests, Pa. 374, R.I. 788.
- Peptones, bacteriological, preparation, 621.
- Peregrinator biannulipes*, predator of bamboo powder-post beetle, 237.
- Perennials, injection of carbon disulfide to kill roots of, Calif. 200.
- Pericarditis, induced cases in dairy cattle, 279.
- Peridermium strobil*, see White pine blister rust.
- Perilla—
 - adaptability tests, Ga.Coastal Plain 374.
 - variety tests, Ga.Coastal Plain 363.
- Periplaneta americana*, see Cockroach, American.
- Perkinsiella vastatrix*, transmission of Fiji disease virus by, 385, 816.
- Permeability of soil, studies, Calif. 170.
- Pexosis, see Chicks, slipped tendon in.
- Persimmon *Cephalosporium* wilt, U.S.D.A. 49.
- Persimmons, disease attacking, 232.
- Pest—
 - control, chemistry and toxicology, 391.
 - control, patents relating to, U.S.D.A. 242.
 - eradication work in Florida, 238.
- Petunia, diploid, tetraploidy and octoploidy induced by colchicine in, 496.

- Petunias, variety tests, Pa. 374.
Pezizula hamamelidis n. sp., notes, 491.
Pezizula spp. and their conidial stages, 491.
Phaenus triangularis, notes, P.R. 250.
Phalaenoides glycine parasite, 82.
Phalaris tuberosa, notes, Idaho 638.
Phaulacridium vittatum, notes, 244.
 Pheasant, ring-necked, winter survival, food and cover relations, 237.
 Pheasants—
 artificial incubation of eggs, 264.
 gapeworm-infested, treatment with iodine, 425.
 hardest type, Wis. 67.
 melanism in, inheritance, 357.
 ring-necked, equine encephalomyelitis in, 423.
 ring-necked, fall foods of, 539.
 ring-necked, parasites, 105.
Phenacoccus aceris, parasite of, biology, 923.
Phenacoccus hirsutus, new parasite, 809.
 Phenol-contaminated waters, physiological action, 107.
 Phenological practice, consideration of, 169.
 Phenolphthalein, analytical methods and collaborative studies on, 6.
 Phenothiazine—
 and its oxidation derivatives, fungicidal activity, 657.
 experiments with, 807.
 Philippine Islands, technical progress made in, 758.
Philocalla n.g. and n.sp., notes 820.
 Phloem, structure and function, relation, 181, 346.
Phloe genus, geographic relations in, 181.
Phlyctaenodes bifidalis, new pest of cotton in Brazil, 76.
 Phoma—
 disease of peach, U.S.D.A. 525.
 terrestris, notes, 532.
 terrestris on onion roots, 526.
Phora incassata, notes, 78.
Phoranthella mendesi n.sp., description, 251.
Phormia regina, notes, Calif. 273.
Phormia terrae-novae of sheep in western Scotland, 79.
 Phosphatase—
 blood and bone, activity, measuring, 694.
 in blood of laying hen, variations in, 260.
 in plasma and whole blood of fowls, 260.
 pasteurization test, practicability, N.Y. State 267.
 role in eggshell formation, 260.
 test, application to sour cream and sour cream butter, 271.
 test applied to ice cream, factors affecting, 569.
 test, practical application, 704.
 tests, procedures for making, evaluation 704.
 Phosphate—
 availability, greenhouse tests, Ky. 476.
 availability in soils, effect of exchangeable cations, 483.
 phosphate—Continued.
 deficiency in soils, prognosis, chemical data in, Calif. 482.
 fixation and availability, effect of degree of base saturation of soils, Del. 343.
 fixation by clay minerals, Okla. 13.
 fixation, role of kaolinite in, Calif. 484.
 from dipotassium phosphate solution, fixation, Tex. 14.
 requirements of soil, determination, effect of arsenical treatments, 6.
 Phosphates—
 better grazing with, Miss. 774.
 comparison, Idaho 617, Ind. 617.
 determination, improved molybdenum blue reagents for, 328.
 effect on nitrifying capacity of soils, 177.
 field tests, Ky. 476.
 in soil and in crop plants, Mont. 178.
 in soil extracts, determination, Taylor phosphate slide comparator for, 328.
 insoluble, availability to sugarcane, 370.
 relative efficiencies, Ind. 617.
 response of Korean lespedeza to, effect of limestone, 642.
 tests, Pa. 13.
 Phospholipid metabolism, radioactive phosphorus as indicator, 88, 690.
 Phosphorus—
 absorbed by roots, upward movement of, 629.
 and calcium depletion and replacement rats on human dietary, 740.
 deficiencies, effect on reproduction in cows, Oreg. 96.
 deficiency among cattle, Pa. 98.
 deficiency in beef cattle rations, effect, Calif. 254.
 deficiency in cattle, causes, Pa. 86.
 determination in fruits and fruit products, 329.
 fixation and availability in soils, Del. 170.
 fixation by horizons of various soil types, 178.
 in alkaline soils, solubility and fixation, Nebr. 761.
 in blood of laying hen, variations in, 260.
 in milk, effect of supplemental phosphorus in ration, Mass. 562.
 in plasma and whole blood of fowls, 260.
 in soil, studies, Hawaii 617.
 inorganic, in blood of dairy cattle, 266.
 metabolism in normal and rachitic chickens, 694.
 metabolism on low-protein and on medium-protein diet, 596.
 new forms, testing, N.Y. State 211.
 requirements of lactating cows, 266.
 role of, Wis. 4.
 Photography—
 outdoor, portable stand for, U.S.D.A. 241.
 specimen supports for objects photographed from above, U.S.D.A. 240.
 Photometer, photoelectric, Ind. 613.
 Photomicrography, fine grain processing and condenser illumination enlarging in, 763.

Photoperiodic response—

of dill, 765.

of spinach, effect of temperature, 765.

Photosynthesis—

chemical aspects, 620.

chlorophyll-carbon dioxide ratio during, 623.

daily rate of two tomato varieties, 181.

effect of indole-3-acetic acid, 632.

formation of a carbon dioxide-combining intermediate during, new evidence, 181.

in *Chlorella*, quantum efficiency, 180.in *Chlorella*, role of magnesium in, 191.

light-mass absorption during, 181.

of apple leaves, effect of dilute liquid lime-sulfur sprays, 799.

of entire apple tree, effect of sulfur dust on rate, 799.

time course shown by glass electrode, 21.

Phycomyces blakesleeanus, synthesis and destruction of vitamin B₁₂ by, 349.*Phyllophaga*, new and little known from Texas, 821.*Phyllophaga* spp., pupation depths, 821.*Phyllosticta riridis* leaf spot of ash, 536.*Phymata pennsylvanica americana*, insect-preying habits, 545.*Phymatotrachelum omnivorum*—

carbohydrate utilization by, 182.

carbohydrates, activity, 182.

cytology and host parasite relations, Tex. 50.

growth, effect of alkaloids from *Sanguinaria canadensis*, 657.

growth in soils containing crude petroleum, Tex. 50.

growth on decoctions from roots of woody plants, Tex. 50.

life history studies, Tex. 50.

root rot, distribution and prevalence in shelterbelt planting area of Oklahoma, 381.

root rot immunity in monocotyledonous plants, basis of, Tex. 50.

sclerotia behavior, unusual features in, 381.

sclerotia, number and viability, Tex. 51.

strand formation, Tex. 50.

Physaloptera felidis, coyote as host to, 571.

Physicians, rural, characteristics and mobility, 189.

Physiology, comparative, textbook, 838.

Phytinus subgenus, revision of beetles of, 821.

Phytic acid, utilization by animals, mechanism, Wis. 141.

Phytin-P, availability to chicks, 262.

Phytohormone tests—

constant temperature constant humidity chamber for, 180.

low cost chamber for, 763.

Phytomonas—*angulata*, inoculation and longevity studies, Ky. 526.*coraci*, cankers induced by, rise and fall in activity, Calif. 336.*delphini*, notes, 62.*Phytomonas*—Continued.*malracearum*, survival, effect of sulfuric acid treatment, Tex. 51.*pruni*, notes, 533.*sepedonica*, notes, 529, Me. 797.*solanacearum*, control, Fla. 221.*stewartii*, native host of *Tripsacum dactyloides*, 60.*tabaci* and related forms, studies, 182.*tabaci*, inoculation and longevity studies, Ky. 526.*tabaci*, notes, 524.*Phytomyza atricornis*, damage to parks and private gardens, 79.*Phytophaga destructor*, see Hessian fly.

Phytophaga in China, catalog, 400.

Phytophthora—*capsici*, notes, 47.*cinnamomi*, notes, La. 656.

disease of hops, U.S.D.A. 48.

infestans, see Potato blight, late.*parasitica nicotianae*, notes, Ga.Coastal Plain 378.

spp., isolation, 52.

stem rot of *Lycchnis riscaria*, 667.

Pickles, health value, 593.

Pigs—

brooders, electric, Ind. 720.

carcass data, analysis and interpretation, 259.

fat, acids in, 693.

Pigeon pox—

immunization of birds against, 719.

natural outbreak, 837.

Pigeonpeas, nutritive values, P.R.Col. 255.

Pigeons, parasites, Hawaii 671.

Pigment, black, of soil, geographical distribution, 480.

Pigs—see also Sows and Swine.

birth mortality, causes and prevention, [N.Y.]Cornell 85.

blood of, hemoglobin content, 422.

buying, accuracy of live weight basis and differences in grade carcasses, Iowa 120.

Canadian, export markets for, 724.

carcass grade of, Ind. 688.

conformation and anatomical composition of body, role of growth curve in, 403.

crossbred v. purebred, from double litters, S.C. 86.

crossbreeding for pork production, Iowa 772.

economical production, transmission of factors related to, Ala. 84.

experiments in Texas, 404.

fall, fattening, corn v. ground cane seed for, S.Dak. 255.

fasting, transit shrinkage, 259.

fattening, Del. 254.

fattening, comparison of alfalfa pasture v. dry lot for, Wyo. 554.

fattening, comparison of grazing crops, Fla. 255.

fattening, floored pens v. large dry lots, S.C. 86.

Pigs—Continued.

- fattening on rye forage, protein supplements for, S.C. 86.
- fattening, Sudan grass and oat pasture for, Tex. 87.
- fed grain sorghums, need of protein supplement, Nebr. 689.
- feeding experiments, Ky. 553, Nebr. 404
- growing and fattening, protein mixtures for, Ind. 688.
- growth and metabolism in, relation to vitamin B complex, 403.
- growth and reproduction, effect of fluorine in rock phosphate, 403.
- growth, effect of kidney worms, S.C. 103.
- improved strains, value of Danish Landrace in development, Iowa 27.
- improvement in Canada, 259.
- industry in France, U.S.D.A. 292.
- industry in Sweden, U.S.D.A. 432
- market, production, value of fortified cod-liver oil in, N.J. 559.
- narcosis and anesthesia in produced by pentobarbital sodium, 111.
- new ear defect in, 193.
- newborn, death loss in, Ind. 707.
- normal growth curve for, 93.
- nutrition, effect of nicotinic acid, 693.
- nutrition, role of riboflavin and other vitamin B complex factors, 559.
- on soybean oil meal rations, mineral requirements, Wis. 554.
- outcrosses, inbred sows v. inbred boars in, 497.
- Poland China, effect of inbreeding, Iowa 27.
- prenatal development, effect of protein levels, Okla. 85.
- prices, index number, N.Dak. 181.
- production, Okla. 854.
- protein requirements, Pa. 86.
- proteins, vitamin, and mixed supplements for, [N.Y.]Cornell 85.
- pure bred, advanced registry for, 259.
- receiving cottonseed meal, calcium requirements, Tex. 87.
- scoring, methods for, 497.
- self-fed, in dry lot, corn v. sorghum grain for, Nebr. 689.
- selling based on dressing percentage and carcass grade, 403.
- suckling, growth, relation to milk production of sow, 692.
- suckling, rations and methods of feeding, [N.Y.]Cornell, 85.
- summer, fattening, S.Dak. 255.
- testing station in Canada, 259.
- trucked to market, shrinkage, fill, and yield, Ind. 688.
- vitamin A requirements, Tex. 87.
- vitamin B requirements, Calif. 254.
- vitamin D requirements, 693.

Pimpla exanimator hosts and host selection, 82.

Pine—

- blister rust, see White pine blister rust.

Pine—Continued.

- disease of sheep, effect of cobalt salts, 259.
 - drought resistance, relation to transpiration and properties of leaves, 794.
 - forests, burned and unburned, moisture relations of soils, 338.
 - growth, factors limiting, Wis. 521.
 - in diet of white-tailed deer, 219.
 - jack, cones, release of seeds from, 376.
 - loblolly, sapwood, rate of decay, 536.
 - longleaf, reproduction, factors in, 376.
 - Norway, plantations, effect of spacing on growth, 377.
 - planted under hardwoods, growth, Ala. 46.
 - ponderosa, mortality in cutover stands, 522.
 - ponderosa, thinning, use of sodium arsenite in, 377.
 - red, drought resistance, effect of soil nutrients, 794.
 - red, fire wounds, protective action of resin in, 65.
 - sawfly, introduced, control, 670, Mich. 253.
 - sawfly, red-headed, control, Mich. 253.
 - seedlings, white and red, cumulative solar radiation and dry weight increase, relation, 218.
 - shoot moth, European, Conn.[New Haven] 540.
 - shortleaf, germinating seed, response to different pH and calcium concentrations, 181.
 - slash, seedlings, root response to indolyl-butyric acid, 521.
 - slash, trees, fertilizer and adaptation studies, Tex. 41.
 - southern, springwood and summerwood of four species, variation in specific gravity, 522.
 - southern yellow, strength of, effect of steaming, 582.
 - species, natural distribution, damping-off as factor, 65.
 - tip dieback in Nebraska, U.S.D.A. 220.
 - Torrey, characteristics, 219.
- Pineapple—
- black rot, control in transit, U.S.D.A. 62.
 - bran for fattening pigs, value, Hawaii 687.
 - diseases, P.R.Col. 527.
 - plants in soil cultures receiving ammonium or nitrate salts, distribution of components, 626.
 - yellow spot, geographical distribution, 62.
- Pineapples, oxalates in, 865.
- Pinus* spp., life histories, 246.
- Pink root, U.S.D.A. 655.
- Pipunculius* spp., new and little known in Utah, 549.
- Pyroplasma gibsoni* in dogs, 718.
- Pyroplasma trautmanni* of swine, 845.
- Pistachio nut trees, pests in Greece, 71.

Pistol casebearer, Pa. 70.

Pituitary—*see also* Hypophysis.

activity of rat, effects of light and darkness, 359.

anterior—

action of oestrin and progesterone on, 199.

of cattle, effects of formalin on thyroid-stimulating and gonadotropic hormones, 199.

of growing rabbits and guinea pigs, lactogen in, 637.

effect of testosterone on, 773.

follicle-stimulating and luteinizing hormones, chemical differences, 360.

follicle-stimulating and luteinizing hormones, extraction and standardization, 360.

gland, changes in, effect of vitamin A deficiency, 771.

gland, effect on reproduction and lactation cycles, 359.

glands of male and female rats, gonad-stimulating abilities, 196.

gonadotropic hormone, augmentation by chlorophyll, plant growth hormones, and hemin, 360.

gonadotropic hormones, characterization by sugar and glucosamine in, 198. in dog and rabbit, operative technic in removal, 359.

of female rat, biphasic effect of male sex hormone on, 360.

of female rat, lactogen content, effect of oestrogen injections, 31.

rabbit, hormone content, age and sex differences, 362.

Placenta, rat, corpus luteum-stimulating substance in, 197.

Placental endocrine activity in mice, criteria, 359.

Plasmodiopsis, new taxonomy in genus, 52.

Platylabus versicolor, parasite of, 551.

Plasmodium, *Oeratosomella* affecting, U.S.D.A. 378.

Plant—

alkaloids, relation to *Phymatotrimum omnivorum*, 182.

alkaloids, treatise, 471.

association, individualistic concept, 486.

associations on land, 486.

breeding and agricultural problems, handbook, 156.

breeding and selecting for insect resistance, 241.

breeding, developments in, 751.

breeding for resistance to insects, 806.

breeding of resistant races, 770.

breeding, Spragg memorial lectures, 25. buds, X-radiation of, effect on floral development, 485.

bugs, control in citrus groves, 245.

callus, excised, growth in artificial nutrient, 181, 188.

cell and animal heart, rhythmical impulses in, 620.

Plant—Continued.

cell division, cell enlargement, and growth rate, relation, 180.

cell wall, microfibrillar and microcapillary structure, 184.

cells, freezing, role of synaeresis in mechanism, 184.

cells, living, technic for study, 180.

cells, vital staining, 493.

cells vitrified in liquid air, vitality, 181.

chromosomes, *see* Chromosomes.

communities, types, *Orihaea* spp. on, 678.

communities, unistratal concept, 486.

cuttings, effect of root-inducing substances, Fla. 210.

cuttings, root formation in, effect of growth-promoting substances, Okla. 40. cytogenetics and radiation, 26.

decomposition, heat evolution in, fermentation calorimeter for study, 621.

destruction in economic history, 290.

disease—

resistance in crops, 26.

situation in Massachusetts, U.S.D.A. 794.

survey, Del. 221, Iowa 49, Nebr. 656, S.C. 50, Wash. 222.

survey, Canadian, report, 795, 796. survey in Winter Garden area, Tex. 52.

viruses, inhibition by insect juices, 52.

diseases—*see also* Fungi and different host plants.

danger of introducing, 796.

handbook, 47.

in greenhouse, Wash. 222.

in Hawaii, Hawaii 655.

in southern California, U.S.D.A. 525.

not previously reported in Texas, Tex. 51.

of ornamentals, N.J. 536.

of ornamentals due to soil-infesting organisms, Mass. 526.

soil-borne, control, Tex. 51.

virus, causes, 223.

virus, in China, 223.

virus, intracellular inclusions, 379.

virus, spread in Aroostook Co., Me. 49.

virus, tabular list, 379.

ecology, trends in, 620.

growing points, cellular relations during growth and differentiation, 620.

growth—

effect of boron, Ky. 526.

in water and sand cultures, 788.

inhibition, correlative, 769.

inhibitor, 24.

physical effects in tillage, Ala. 115.

role of thiamin in, 189.

substances, assay method for, 22.

Plant—Continued.

growth—continued.

substances for rooting forage plant cuttings, tests, 303.

substances, physiology and chemistry, 310.

substances, studies, 620.

hormones, *see* Growth substance(s) and Plant growth substances.

indicators, concept and status, 24.

injection for rapid diagnosis of mineral deficiencies, 41, 190.

inoculations, insect vectors used in, small cage for, 656.

irrigator and recorder, automatic, 620.

lice on peas and roses, oil-nicotine spray for control, Ky. 540.

nutrition—

and bacterial virulence, 524.

antagonism of certain elements toward chemically related toxic elements, 353.

foliar diagnosis, Pa. 40.

mineral, 620.

minor elements in, 186.

mode of, recent findings, 623.

physiological phases, Fla. 170.

relation to social and economic life of South, 861.

value of minor elements in Oregon soil, 619.

parts, excised, cultures, nicotinic acid in, 180.

parts, excised, method for culture, 25.

pathogens, bacterial, gram-negative, systematic position and generic names, 796.

pathogens, seed-borne, laboratory technique for detecting, Iowa 48.

pathology, elements of, treatise, 523.

pathology projects in Hawaii, 385.

pathology research, fifty years of at Florida Station, 655.

pests, control, legislation in United States for, U.S.D.A. 242.

pests in Scotland, 69.

phloem tissue, development and structure, 625.

physiology in women's colleges, 340.

population, alien, of California, 621.

protection, 751.

quarantine act and quarantine No. 37, U.S.D.A. 242.

residues, thermophilic decomposition in composts, 342.

roots and soil colloids, cation interchange between, 187.

rust fungi, taxonomy, Ind. 655.

seedlings, etiolated, respiration, effect of calcium deficiency, 767.

species, concept based on experiment, 355.

taxonomists, proposed establishment of an international society, 620.

tissues—

effect of calcium on, 449.

Plant—Continued.

tissues—continued.

formation of glucosides from introduced aglucons, 150.

freezing point depression, effect of variables on, 181.

of different types, rate of decomposition, 481.

polar, transport of inorganic ions in, 630.

preliminary inhibition and final stimulation by toxic substances, 630.

primordial, comparative effects of X-radiation and treatment with growth-promoting substances, 485.

sugars in, determination, 329.

viruses—

chemistry of, 223.

history of research, outlines, 751.

nomenclature, 222, 524.

properties, 379.

recent work on, 222.

separating and identifying, new laboratory procedure for, Wis. 527.

transmission by insects, 379.

Plantain—

diseases, P.R.Col. 527.

insects, 240.

Plants—*see also* Flora and Vegetation.

adaptation studies, Tex. 41.

aging in, 346.

annual and perennial for sun and shade, Miss. 787.

aquatic, nutritive value and chemical composition, Minn. 555.

aquatic, requirements for storage and germination of seeds, [N.Y.]Cornell 18.

blossom formation, anatomical changes preceding, 181.

blossom-inducing stimulus, point of origin, 764.

chloroplasts from, quantitative isolation, 20.

chromosome number and cell size, effect of colchicine, 355.

scab, control, 530, N.Y.State 529.
scab immunity, 227.
scab, notes, [N.Y.]Cornell 49, Nebr. 656.
scab resistance, variations in degree of, Wis. 527.
scab resistant breeding stock, development, Wis. 527.
scab, sulfur for control, Tex. 51.
seed piece rot control, Hawaii 655.
seed plots, Green Mountain, strain test for diseases, Me. 49.
spindle sprout, studies, Hawaii 638, U.S.D.A. 525.
sprain, straw as aid in prevention, Wis. 527.
tipburn in New York, U.S.D.A. 794.

Potato—Continued.

- tissue cells, adhesion, effect of pectic solvents and precipitants, 804.
 tuber buds, inhibition of growth with vapor of methyl ester of naphthaleneacetic acid, 633.
 tuber cells, adhesion, effect of heat, 591.
 tuber tissue, penetration by *Rhizoctonia solani*, relation to seed treatment, 661.
 tuber tissue, permeability, effect of heat, 592.
 tubers, breaking dormancy, relation of oxygen to carbon dioxide in, 348.
 tubers, cut surface, bud growth and initiation of roots, control, 180.
 tubers, diseased, suberin and suberized deposits of, 56.
 tubers treated with ethylene chlorohydrin, synthesis of β -(2-chloroethyl)- α -glucoside by, 348.
 yellow dwarf, factors affecting, Wis. 527.
- Potatoes—**
 as carriers of vitamin C, 882.
 breeding, Hawaii 638, Iowa, 33, N.Dak. 35, N.Y.Cornell 34, Nebr. 363, 639, Pa. 35, Wash. 201, Wis. 502.
 breeding for quality, yield, and disease resistance, Pa. 50.
 bruising, freezing, and chemical injury in transit, U.S.D.A. 207.
 changes in technology and labor requirements, 433.
 Chippewa, merit, Miss. 774.
 cold resistance in, nature, Nebr. 623.
 composition and culinary quality, [N.Y.] Cornell 34.
 cooking quality, Me. 141.
 cooking quality, predetermining, Mich. 303.
 cooking quality, variability in, 779, N.H. 864.
 cull, value for wintering rations of ewe lambs, Idaho 688.
 culture and storage, 642.
 culture experiments, Fla. 200, Hawaii 638, N.Mex. 775, Nebr. 363, Tex. 37, Wyo. 503.
 damage by digging machinery, 779.
 dormancy, oxygen regulation, 181, 633.
 early, fertilizers for, 779.
 effect of storage temperature and atmospheric composition, 181, Wash. 201.
 efficiency of spraying and dusting on muck soils, [N.Y.]Cornell 66.
 Epicure, resistance to nematodes, 530.
 fall-crop, yields, Okla. 35.
 fertilizer and liming studies, La. 639.
 fertilizer and nutrition studies, 368.
 fertilizer experiments, Alaska 362, Conn. [New Haven] 501, Fla. 200, La. 639, Me. 34, Mich. 779, N.Mex. 775, Oreg. 35, P.R.Col. 502, R.I. 775, S.C. 36, Tex. 37, Wash. 201, Wyo. 503.
 fertilizer placement, 363, U.S.D.A. 507.
 formation of flower primordia, factors affecting, 21.

219370-40—10

Potatoes—Continued.

- green manure for, Tex. 37.
 harvesting, Pa. 115.
 household storage, 593.
 Idaho, competition, Idaho 723.
 improvement, 206, [N.Y.]Cornell 49.
 Katahdin, showing resistance to virus diseases, Idaho 655.
 low average yields in Ohio, reasons, 368.
 marketing 431.
 marketing, methods and costs, Pa. 129.
 modification of sprouting by chemical treatments, Idaho 638.
 nutrition, foliar diagnosis, Pa. 36.
 Ohio, marketability, 779.
 Peruvian, photoperiodic reactions and virus contents, 384.
 planting and source of magnesium tests, R.I. 775.
 pollen sterility in, inheritance, 495.
 Pontiac, description, Mich. 206.
 Porto Rico, nutrient deficiency symptoms and yields, S.C. 36.
 prices, index number, N.Dak. 131.
 production—
 in central Maine, costs and returns, Me. 127.
 new developments in, 206.
 on mineral soils, 206.
 on muck, 206.
 role of green manure in, 206.
 response to limestone and basic slag, S.C. 36.
 rhizoctoniosis and pitting, [N.Y.]Cornell 49.
 rotation experiments, Nebr. 639.
 Russet Burbank, apical dominance and rest period, effect of chemicals, 507.
 seed—
 cut, sun injury to, 367.
 dry land v. irrigated, Wyo. 503.
 effect of length of dormant period on yield, 507.
 handling and storage, [N.Y.]Cornell, 34.
 mercuric chloride for treatment, strength of solutions, Me. 49.
 on sandy and on peat soils, comparative productiveness, 368.
 production, Nebr. 363.
 production of foundation stocks, Nebr. 640.
 production, relation to aphids migration and distribution, 395.
 selfed and hybrid, immediate germination, 368.
 treatment for scab, N.Y.State 222.
 waxing, 207.
 seedling performance in greenhouse and subsequent yield in field, correlation, 368.
 soil management for, Mich. 779.
 sold in city markets, quality, [N.Y.] Cornell 121.
 spray treatments and tuber index tests, Wyo. 503.

Potatoes—Continued.

- spraying and dusting, Me. 49.
- spraying experiments, 206, Mass. 540, R.I. 795.
- spraying in both wet and dry years, value, Wis. 527.
- spring-grown, storage experiments, Okla. 35.
- storage, Nebr. 363.
- storage and nutrition studies, Nebr. 639.
- storage and sprindling-sprout studies Hawaii 638.
- varieties better suited to specific growing conditions, 779.
- varieties, culinary qualities, Wyo. 591.
- varieties, new and old, 206.
- variety tests, Alaska 362, Fla. 200, Hawaii 638, Iowa 33, Ky. 501, La. 639, Mass. 501, Me. 34, Nebr. 363, N.Mex. 775, Okla. 35, Pa. 35, R.I. 775, S.C. 36, Tex. 37, Wash. 201, Wis. 502, Wyo. 503.
- virus X in, inheritance of immunity from, 192.
- vitamin C in, Mass. 591, Wyo. 591.
- White Rose, new variety, Oreg. 35.
- yield and cooking quality, effect of soil reaction and planting date, Pa. 35.
- yields, Alaska 362.
- Poultry—see also Chickens, Chicks, Ducks, Fowls, Hens, etc.
- abnormalities, genetics of, [N.Y.]Cornell 28.
- adult mortality in, genetic approach to control, 357.
- adult, mortality of noninfectious origin, 112.
- age at sexual maturity, effect of varying levels of wheat bran, 828.
- air requirements, Iowa, 84.
- and egg situation, Okla. 535.
- artificial insemination in, 196.
- batteries for, Oreg. 95.
- blood, cell counts made with supravital and Wright's staining technics, 409.
- blood, nonfermentable reducing substance of, 409.
- body fat, effect of fattening foods and temperature, 260.
- breed differences in resistance to vitamin B₁ deficiency, 263.
- breed variations in body form, Okla. 85.
- breeding, Del. 254.
- breeding birds, effect of controlled temperature and different light rays, [N.Y.]Cornell 85.
- breeding, dual purpose, 29.
- breeding for increased livability and egg production, Fla. 255, Ky. 554, Pa. 86, 260.
- breeding, principles, 560.
- breeding small flocks for high fecundity, 192.
- breeds and crosses, transmission of disease resistance and susceptibility to high temperatures. [N.Y.]Cornell 27.

Poultry—Continued.

- breeds, comparative vitamin D requirements, Wis. 554.
- brooders, electric, Ind. 720.
- brooders, insulated electric, adaptation in uninsulated poultry houses, Nebr. 720.
- buying data, Iowa 121.
- cannibalism in, effect of components of rations, S.C. 86.
- cecal worms in Hawaii, 578.
- cestode in Hawaii, life history, 577.
- comb atrophy after adult castration in Bantam cocks, 500.
- comb growth in capon Bantams, effect of temperature on response to androsterone, 500.
- Congress World's, editorial, 405.
- conversion of phosphate to lipid phosphorus by tissues, 88.
- cross-breeding for meat production, Hawaii 29.
- digestive tract, pathological conditions of anterior portions, 577.
- disease, hitherto undescribed, in Palestine, 718.
- disease resistance, breeding for, Hawaii 688.
- disease resistance in, West.Wash. 424.
- diseases—see also specific diseases.
- autopsy examinations for determination, R.I. 834.
- in Mysore, 837.
- laboratory diagnosis, Ind. 707.
- effect of varying levels of alfalfa leaf meal, R.I. 827.
- farms, economic data, R.I. 854.
- farms, labor income on, Mass. 535.
- fattening methods, 561.
- feeding and management, Nebr. 404.
- feeding, free-choice v. all-mash, Ky. 554.
- feeds, mixed, stability of vitamins A and D in, 257.
- flocks, effect of all-night lighting during winter months, Okla. 85.
- flocks, progeny tests in, effects of culling, 28.
- genetic studies, Okla. 28.
- grazing, year-round, ryegrass, mustard, and Bermuda for, Miss. 825.
- growth and reproduction, new factor required for, 409.
- hatchery industry in Maryland, Md. 858.
- house cooling, Calif. 287.
- house heating, Ind. 720.
- houses, all-steel or semisteel, temperature conditions, Hawaii 658.
- houses, effect of ventilation, heat, and humidity conditions in, Ind. 688.
- houses, old laying, modernization, Ohio 584.
- inbreeding and cross-breeding, effect, Iowa 27.
- industry, Government aid for, U.S.D.A. 859.
- industry, western and marketing problem, 724.

Poultry—Continued.

- killing, electrical methods, 561.
- leg bones and organs, distribution of phosphorus in, 694.
- leg weakness in, 837.
- management, phases, Ind. 638.
- market, gains and quality, effect of ration and fattening period, Iowa 84.
- marketing in Wilmington, Del. 295.
- mortality, causes, Calif. 273.
- mortality, disease factor in, 424.
- mortality, possibility of decreasing, Idaho 638.
- of various ages calcium and phosphorus contents, 828.
- optimum crude fiber level for, Okla. 85.
- parasites, Hawaii 671.
- parasites, transmission by birds, 235.
- prices, index number, N.Dak. 131.
- producers of central California, financial structure, 588, Calif. 290.
- protein requirements, N.H. 694.
- publications, bibliography, U.S.D.A. 93.
- ration, complex mineral mixtures in, value, Nebr. 689.
- rations, effect of applying heat to, Nebr. 689.
- rations, high and lower grades of grain in, comparison, S.Dak. 255.
- rations, wheat as corn substitute in, Ind. 688.
- reproduction in, antidermatosis vitamin requirement, 410.
- respiratory diseases, prevention and control, R.I. 846.
- Rhode Island Red selected strains, differences in, Mass. 498.
- Rhode Island Reds, fertility in, Mass. 636.
- sanitation and disease control, 286.
- sugar tolerance in, 84.
- susceptibility to reinfection with tapeworm, 104.
- tolerance for fat, Iowa 84.
- virus diseases of, 570.
- vitamin A requirements, Pa. 86.
- vitamin and mineral requirements, 404.
- vitamin B complex members requirements of, Calif. 254.
- vitamin G complex requirements, [N.Y.] Cornell 85.
- vitamin requirements Wash. 255.
- yards, sulfured soil for, 286, 830.

Poult—

- improved rations for, Wis. 554.
- manganese requirements, Nebr. 639.
- slipped tendon in, effect of proteins and inorganic elements in ration, Iowa 84.
- Powder-post beetle, bamboo, predator of, 237.
- Powder-post borer, preservation of timber against, 686.

Prairie chicken—

- Attwater, ecology, Tex. 68.
- greater, breeding in Iowa 237.
- of Wisconsin, 804.

Prairie—

- hay and cottonseed cake, ineffectiveness for wintering beef heifers, Tex. 87.
- hay, vitamin A potency, Okla. 96.
- species, bound water in, relation to environment, 181.
- subclimax, 180.
- Pratylenchus pratensis*—
 - attractiveness of roots and external shoot tissues to, 537.
 - biology, 234.
- Prasibulus laminatus*, notes, 244.
- Prays citri*, control, 518.
- Precipitation—see also Rainfall, Snow, etc.
 - and water supply in Sierra Nevada region, 333.
 - intercepted by forest canopies, measurement, 376.
 - relation to stream flow on Salt River watershed above Roosevelt Dam, Ariz. 580.
- Predators on mixed prairie area, ecological evaluation, 235.
- Pregnancies, toxemic, on pork diets, dietary factors in production and cure, Iowa 140.
- Pregnancy—
 - duration, factors affecting, 637.
 - maintenance by progesterone in castrated rabbits, 199.
 - test, use of unextracted serum for, improved technic for test, 360.
 - urine extract, effect on lactation in rat, 361.
 - urine extract, induction of mating in dog with, 361.
- Prenolepis longicornis*, see Ants, crazy.
- Pressure cooker gages, calibration of for high altitude, Wyo. 591.
- Price—
 - analysis, graphid method, 431.
 - averages, past performance, 725.
 - changes, long-time, and farm operation, 430.
 - fixing policies, aspects, 431.
 - incidence of a duty, determination of limit on, 290.
 - incidence of a duty, determination of limit on, correction, 585.
 - spreads between farmer and consumer, U.S.D.A. 440.
- Prices—
 - paid by farmers for commodities and services, U.S.D.A. 439.
 - stabilization, practice of, 431.
- Pricklypear, see Cactus.
- Prionoxystus robiniae*, see Carpenter worm.
- Proactinomyces, studies, 621.
- Prodenia*—
 - eridania*, see Armyworm, southern.
 - littoralis*, life history notes, 396.
- Progesterone—
 - and 3.20-allopregnanolone, isolation from ox adrenals, 199.
 - androgenic properties, 500.
 - effect on ovariectomized rats, 199.
 - effect on pregnancy of castrated rabbits, 199.

Progesterone—Continued.

- injections in ovariectomized guinea pigs, effect, 361.
- uterine injection, effect on mucous membrane of infantile rabbits, 362.

Promecotheca nuciferae, Javan parasite of, 69.

Propagation wounds, grafting waxes for covering, Okla. 40.

Prophanurus alecto in Puerto Rico, 238.

Propionic acid bacteria—

- CO₂ utilization during dissimilation of glycerol by, 622.
- nitrogen and accessory growth factor requirements, Iowa 4.
- products of, Wis. 4.

Prosthogonimus macrorchis, disease in turkeys due to, 425.

Protein—

- feeds for growing chicks, comparison, Tex. 93.
- value of various concentrates, Wash. 255.

Proteins—

- added to maintenance ration, specific dynamic effects, 739.
- aldehyde condensation products, N.Y. State 165.
- animal, for swine, 692.
- in green leaves, metabolism, 22.
- in human nutrition, egg-replacement value, 305.
- in protein-rich supplements and in legume and nonlegume rations, nutritive value, [N.Y.] Cornell 85.
- in rats, lactation-promoting properties, 702.
- native, denatured, and coagulated, theory of structure, 22.
- specific dynamic action, Pa. 86.
- studies, Conn.[New Haven] 469.
- virus, properties, 52.

Prothrombin content of blood of newborn infants, fluctuation in, 869.

Protoperce—

- quinquemauiata*, see Tobacco worm.
- sesta*, see Tomato worm.

Protopectinase, detection, use of sectioned plant material for, 182.

Protoplasm and its derivatives, submicroscopic morphology, 19.

Protoplasmic—

- coagulation, time and temperature, 346.
- permeability, estimation from plasmolytic tests, 346.

Protostrongylus rashi, new lungworm from mountain sheep, 835.

Protozoa in feces, technic for discovery, 104.

Protozoan cysts obtained from feces, hematoxylin staining, 104.

Proventricular worm, parasite of ruffed grouse, Mich. 806.

Prune—

- dieback, Calif. 220.
- drought spot, 801.
- drought spot, relation to boron content of fruit, 666, Idaho 655.

Prune—Continued.

- products, new, Oreg. 10.
- thrips, control, Oreg. 68.
- thrips, control by sprays, 245.
- trees in Wenatchee-Okanogan District, Wash. 587.

Prunes—

- dried, notes, Calif. 165.
- production, prices, marketing outlets, etc., Calif. 290.

Prunus—

- pollen tube growth in, 215.
- spp., California native, rust on, 534.
- virus diseases in Bulgaria, 61.

Psallus seriatus, see Cotton flea hopper.

Pseudaspidohera jnanendae n.sp. from pea-towl, 810.

Pseudococcus—

- kenyae*, studies, 75.
- sp. of coffee, 393.

Pseudogalls, aphids, auxins, and galls, 180.

Pseudomonas—

- aeruginosa* in bovine mastitis, 108.
- fluorescens* group of plant pathogens, 796.
- fluorescens* in sterile soil, accuracy of plate count of pure cultures, 15.
- fluorescens*, notes, 524.
- mephitica*, proposed name, 415.

Pseudoparietaria ostreata on papaya trees, control, P.R.Col. 541.

Pseudoperonospora cubensis, control, La. 656.

Pseudopeziza ribis, notes, 232.

Pseudorabies, see Paralysis, infectious bulbar.

Psila rosae, see Carrot rust fly.

Psocids in dwellings, 678, 815.

Psorophora spp. in rice fields, Ark. 548.

Psoroptes communis botis, parasite of carabos in Philippines, description, 714.

Psorosis prevention, disease-free parents for, 232.

Psyllid yellows—

- control, N.Mex. 775.
- of potato and tomato, 380.

Psyllids, new species, 679.

Pterandrus rosa, notes, 815.

Pterostichus chalcites, feed record on June beetle eggs and grubs, 237.

Ptinus villiger, see Spider beetle, hairy.

Puccinia—

- anomala*, notes, 892.
- coronata*, development, factors affecting, 660.

n.spp., description, 223.

Pucciniospora caricae, notes, Tex. 52.

Puerto Rico College Station, report, 604.

Pullets—

- acute infectious disease of, 113.
- confinement v. range conditions, egg production and mortality, Fla. 255.
- cost of raising by different methods, Wyo. 554.
- egg production and livability, effect of management, 827.
- fat balance studies on fat-low and normal rations, 84.

Pullets—Continued.

laying, battery cages v. pen management, N.Mex. 825.

Leghorn, response to artificial lighting, Ind. 683.

periodical trap-nesting value, 697.

White Leghorn, eggshell thickness in inheritance, 194.

White Leghorn, value of artificial light for, Del. 254.

Pullorum disease—see also *Salmonella pullorum*.

agglutination tests for, Ind. 707.

eradication, Mass. 569.

in poultry, detection, Idaho 707.

in turkeys, Calif. 273, Mass. 569.

in turkeys and carriers, 423.

notes, Oreg. 103.

outbreak in young guinea fowl, 114.

transmission experiment, West.Wash. 424.

whole-blood test for, 113, U.S.D.A. 847.

Pulp and paper, list of publications on, U.S.D.A. 10.

Pulse beetle, thoracic mechanism, 810.

Pulses, available carbohydrate and acid-base balance in, 303.

Pulvinaria floccifera, notes, 302.

Pumpkin soot rot, 384.

Pumpkins, household storage, 593.

Purdue University, notes, 159, 320.

Purple scale—

control with lime sulfur, Fla. 238.

infestations, reasons for increase, 546.

toxicity of derris to, Ala. 65.

Pyæmia in foals caused by *Corynebacterium equi*, 423.Pyosepticæmia of calves, *Salmonella enteritidis dublin* in, 837.

Pyralidoid moths, American, cactus-feeding group, 817.

Pyrausta nubilalis, see Corn borer, European

Pyrethrins—

in pyrethrum products, determination, 814.

I and II in household insecticides, determination, 814.

preparation, 814.

Pyrethrum—

evaluation, 814.

fly sprays, terpene ethers in, Del. 675.

growing for insecticidal purposes, Ind. 645.

inactivation after ingestion by southern armyworm, 248.

larvicides for mosquito control, U.S.D.A. 242.

Pyridium, analytical methods and collaborative studies on, 6.

Pythium—

aphanidermatum, notes, Conn.[New Haven] 530.

aphanidermatum root rot of cucurbits, 531.

arthonomæ on wheat roots, effect of salicylic aldehyde in soil, 226, 660.

Pythium—Continued.

homothallism in, 183.

root rot of mello and development of resistant varieties, Calif. 661.

sp. on taro, Hawaii 655.

spp., causing watermelon blossom-end rot, 231.

ultimum causing soft rot of pumpkin and watermelon, 384.

Quackgrass—

control, Wyo. 503.

meadows, early cutting and fertilization, Mich. 207.

response to variations in height of cutting and rates of nitrogen application, 511.

Quail—

artificial incubation of eggs, 264.

bobwhite and ring necked pheasants, comparative ability to withstand cold and hunger, 670.

bobwhite, environmental carrying capacity for wintering, Iowa 65.

bobwhite, fall foods of, 539.

bobwhite, food of in Wisconsin, 670.

bobwhite, in east Texas, Tex. 66.

California Valley, factors in nesting losses, U.S.D.A. 668.

California Valley, nesting cycle, 237.

censusing in early fall, 237.

cytological studies of adult testes from, 498.

increase by improving habitat, 805.

low-density valley, seasonal movements, 805.

management, Wis. 67.

Quassia, bibliography, U.S.D.A. 806.

Quince—

fire blight, [N.Y.]Cornell 49.

flowers, structure, [N.Y.]Cornell 43.

rust, importance on apple, U.S.D.A. 48.

Rabbits—

cottontail, studies, Iowa 66.

deformed feet and defective ears, inheritance, 194.

infantile, uterine injection of progesterone, effect on mucous membrane, 362.

Jack, economic value, N.Dak. 235.

mortality studies, Mass. 569.

resistance to larval cestodes, 849.

streptococcus infections, toxicity and action of sulfanilamide, 840.

susceptibility to virus of endemic typhus fever, 273.

Rabies—

infection of chicks and chick embryos with, 418.

studies, 418.

Raccoon—

ecology and management, Iowa 65.

fall food habits in central Iowa, 668.

Radiation—see also Solar radiation.

and plant cytogenetics, 26.

in bright sunlight, measurements, 835.

Radio as instrument of levelling of rural and urban cultures, 445.

- Radiosond balloon, meteorological application of, 10.
- Radish mosaic disease in California, 57.
- Radishes—
greenhouse, earwig destructive to, 807.
variety tests, Pa. 374.
- Railletina cesticollis*—
effect on growing chickens, 104.
new intermediate hosts of, 105.
susceptibility of chickens to reinfection with, 104.
- Rainfall—see also Precipitation.
and run-off of New England, 475.
and water, new theory, 616.
conduction by trunks of trees in tropical rain forest, 180.
intensity, Indiana regional contrasts in and effects, 475.
- Raisin storages, Coleoptera found in, 821.
- Raisins, notes, Calif. 165.
- Ramie—
fertilizer tests, Fla. 200.
production tests, Fla. 200.
- Rams—
Barbary, attempted crossing with sheep and goats, 28.
purebred mutton, on native ewes, effect on meat and wool of offspring, 407.
- Rancidity, photochemical studies, 165.
- Range—
and pasture research in Texas, 404.
brush, effects of burning, Calif. 200.
cattle, mineral deficiency studies, 404.
cattle, supplemental feeding, value, Calif. 254.
grassland, nutritional studies, Ariz. 91.
lands, vegetational changes as result of furrowing, 777.
plants, composition, relation to management, Calif. 690.
plants, seasonal changes in calcium and phosphorus content, Idaho 688.
rotation, importance, Fla. 253.
- Ranges—
depleted, reseeding with native grasses, Colo. 39.
restoration by artificial revegetation, N.Mex. 775.
studies, N.Mex. 825.
- Raritan River pollution, N.J. 581.
- Raspberries—
black, breeding for anthracnose resistance, Iowa 40.
black, root distribution, 792.
breeding, Wash. 211, West.Wash. 374.
crumbly fruit in, West.Wash. 379.
Cuthbert, translocation of carbohydrates in, 627.
frozen, vitamin C in, Wash. 301.
selection and propagation, Alaska 374.
straw manure mulch v. sodium nitrate for, Ky. 512.
variety tests, Wis. 512.
- Raspberry—
cane borer and related species, control, 807.
- Raspberry—Continued.
crowns and roots, wood decay of, 220.
diseases in New York State in 1938, 231.
insects, control, Mich. 240, U.S.D.A. 806.
mosaic and its vectors, West.Wash. 379.
mosaic and spur blight, control, N.Y. State 222.
mosaic-escaping variety, breeding, 636.
rust, West.Wash. 379.
- Rat blood, partition of arsenic in, 404.
- Rat caries, inheritance in, 192.
- Rat flea, tropical, survival in United States, 685.
- Rat surveys and rat proofing, 804.
- Rats—see also Rodents.
additional nutritional factors required by, 450.
and dogs, comparative nutritive requirements, Ala. 84.
bent-nose in, interaction of genes and diet in, 29.
chemical and pathological changes in aging and after retarded growth, 689.
control in Queensland, 391.
effect of exercise in presence and absence of vitamin A, 557.
effect of lead in diet, 106.
fasting, rate of formation and destruction of phospholipids in, 88.
female, frequency of prostates in, effect of inbreeding and selection, 192.
growth, activity, and composition on diets of different protein levels, 556.
growth, retardation in successive generations, Iowa 140.
-in rice fields of Java, control, 391.
manganese requirements, Pa. 86.
nicotinic acid requirements, 747.
normal and rachitic, bone development in, 740.
on diets restricted in calories, effects, 689.
on human dietary, long-term experiment, 740.
ovariectomized, action of dipropionate and benzoate-butyrate of oestradiol on, 499.
skeletal development, requirement of calcium and phosphorus for, Conn.[New Haven] 594.
spectacle eye in, prevention and cure, factor in vitamin B complex responsible for, Wis. 141.
-water, damaging sugarcane in British Guiana, 236.
- Ravens, white-necked, and crows, food of, comparison, 804.
- Rayon and silk, consumer studies, 886.
- Rayon, development and use, U.S.D.A. 460.
- Records, method of keeping on replicated plots, U.S.D.A. 240.
- Recreational development of Southern Highlands Region, 209.
- Red mite—
control, Pa. 68.
European, control, 392, 543, Conn.[New Haven] 83, 540, Pa. 70.

Red mite—Continued.

- European, control on damsons, spraying experiments, 558.
- European, oil sprays for dormant applications, Mass. 540.

Red scale—

- California, notes, Tex. 67.
- California, spot treatment for, 817.
- toxicity of dinitro-*o*-cyclohexylphenol to, 676.

Red spider—

- control on greenhouse plants, Mass. 541.
- control under glass, 807.
- fruit tree, control, 401.
- mites, identification, Idaho 671.
- notes, Tex. 66.
- on apples, 542.
- on green beans, control, 807.
- on hops, control, 808.
- on hops, ovicidal washes against, tests, 69.
- on papaw, 393.
- orchard, control, Wash. 239.
- sprays for, Calif. 238.
- toxicity of dinitro-*o*-cyclohexylphenol to, 676.

Redwater in Indian buffalo, 422.

Reed canary grass, culture experiments, Iowa 34.

Reforestation, State, in two New York counties, [N.Y.]Cornell 134.

Refrigerating data book, treatise, 288.

refrigeration for farm household and farm produce, Ind. 749.

Regional projects, efficacy for meeting demands, 403.

Regional research laboratories, nature, organization, and projected work, N.Dak. 474.

Regression, relation to selection, 497.

Relapsing fever—

- Ornithodoros hermsi* as probable vector, 104.
- spirochetes, hereditary transmission by ticks, 276.

Relief—

- for unemployables, Wis. 132.
- measures relating to raising of farm prices, U.S.D.A. 131.
- rural, trends in Wisconsin, 590.
- to farm people in West Virginia, extent, W.Va. 182.

Renal calculi, production in guinea pigs on vitamin A deficient diet, 145.

Reproduction, endocrines related to, 498.

Reptiles, birds, mammals, relations, standardization of precipitin technic in studies, 285.

Resazurin—

- in milk, potentiometric studies, 702.
- reduction test, suitability of various brands of dye for use in, 704.
- test, present status, 414.

Respirometers, Warburg, suggestions for use in plant physiology, 620.

Rhabdoonemias obscura, see Sugarcane weevil, New Guinea.

Rhacoonatus scirpophaga, parasite of sugarcane white moth borer, 82, 811.

Rhagoletis—

- cingulata*, see Cherry fruitfly.
- completa*, see Walnut husk fly.
- pomonella*, see Apple maggot and Blueberry maggot.

Rhagoletia, new from Cuba, 545.*Rhinopeltella eucalypti*, notes, 72.

Rhinosporidiosis—

- in equines, 837.
- of bovines in Madras, 837.

Rhipicephalus sanguineus, see Dog tick, brown.*Rhizobium*—

- growth, effect of biotin concentrates, 621.
- strains associated with leumers, 622.
- trifolii*, growth factor requirements, 182.
- trifolii*, soil acidity tolerance, Pa. 36.
- use of carbonaceous materials by, Iowa 13.

Rhizoctonia—

- control, Me. 49.
- infection on potatoes, effect of agronomic practices, 284.
- microsclerotia*, notes, 531.
- on potato, Nebr. 656.

solani—

- bacterium antagonistic to, 223.
- cultural variant, 58.
- penetration of potato tissue by, 661.
- perfect stage in plantings of diseased cotton seedlings, 55.
- physiologic races, determination, 525.

sp., notes, Ga.Coastal Plain 378.

Rhizoglyphus hyacinthi, see Bulb mite.

Rhizopods, soil, new Zoëpagaceae destructive to, 183.

Rhizopus sp., respiration and lactic acid production by, 19.

Rhode Island—

- College, notes, 463, 606, 891.
- Station, notes, 463, 606, 891.
- Station, report, 887.

Rhododendrons—

- jassid enemy of, 395.
- propagation by cuttings, [N.Y.]Cornell 45.

Rhopalosiphum—

- prunifoliae*, see Apple grain aphid.
- peridobrassicae*, see Turnip aphid.
- splendens* infesting wheat, 539.

Rhubarb—

- black tip, West.Wash. 379.
- breeding, Pa. 40.
- culture experiments, Conn.[New Haven] 787.
- juice, preparation, N.Y.State 593.
- leaf, amides of, 186.
- leaf, studies, Conn.[New Haven] 469.
- leaves, exhaled, loss of carbon from during culture, 493.

Rhynchosia herus, damage to fruit, 203.*Rhynchothrips* *des.* notes, Calif. 245.*Elbes* genus in California, 24.

- Ribes* spp., South American, susceptibility to *Cronartium ribicola*, 534.
- Riboflavin**—
in feeding stuffs, determination, [N.Y.] Cornell 6.
low diets, effect on nerves, growth, and reproduction in rat, 878.
requirements of chickens, 829.
- Rice**—
and byproducts, biological value of proteins, 867.
arsenic toxicity to, La. 617.
as green manure, N.Mex. 775.
black kernels in, possible cause, U.S.D.A. 48.
borer, Asiatic, control, 547.
borer, spring brood larvae, 396.
bran, role in prevention of slipped tendon in poultry, Wis. 87.
breeding, La. 639, Tex. 37.
caseworm, life history, habits, and control, 817.
culture experiments, Tex. 37.
date of seeding with grain drill and in water, La. 639.
diseases, La. 661, Tex. 51.
dwarf disease, new insect vector, 75.
fertilizer experiments, Calif. 199, La. 639, Tex. 37.
fertilizers, methods of applying, Tex. 37.
fields of Java, control of rats in, 391.
irrigation, problems of water resources for, Ark. 116.
lands, effect of holding water on in alternate years when not sown to rice, La. 639.
leaf blotch, new disease, 654.
Rhizoctonia disease, 228.
rough, and rice screenings v. corn for fattening hogs, 403.
seed, germination, effects of fertilizers, Tex. 37.
soils, chemical characteristics, La. 477, 617.
stalk borer, La. 674.
stinkbug, La. 674.
stored, insects, field infestation by, La. 674.
strawstacks, source of infection with black kernel disease, U.S.D.A. 795.
tolerance to different soil reactions, Tex. 37.
varieties, progress in improving, La. 639.
variety tests, La. 639, Tex. 38.
weed control with sulfuric acid solutions, Tex. 37.
weevil in corn, S.C. 68.
- Ricketts**—
and cereals, 262.
beryllium, in chickens, 262.
experimental in rats, healing process in bones, 747.
in calves, a regional problem, 703.
in rats, low phosphorus diet for study, 884.
producing diets composed of purified food materials, 879.
- Ricketts**—Continued.
treatment with single massive dose of vitamin D, 745.
- Rickettsiae** of Rocky Mountain spotted fever and typhus groups, developing chick embryo as medium for growing, 277.
- Rinderpest**—
complement-fixation reaction in, 608.
goat blood virus, viability at incubator temperatures, 710.
immunity, possible duration, 838.
syndrome, changes in phosphorus and calcium of blood during, 837.
transmission by stablefly, 837.
- River measurement**, see Stream flow measurements.
- Roaches** inhabiting houses, bionomics, 816.
- Road aggregates**, compactibility, new vibratory machine for determining, U.S.D.A. 427.
- Roads**—see also Concrete pavements.
base-course construction, sand-clay-gravel materials for, U.S.D.A. 287.
bituminous-treated surfaces on sand-clay and marl bases, U.S.D.A. 427.
capacity studies, U.S.D.A. 118.
construction, affinity of hydrophilic aggregate for asphaltic bitumen, 582.
design, relation to speed and transition curves, U.S.D.A. 118.
low-cost, construction, use of bitumens in, 118.
toll and free, U.S.D.A. 851.
use studies, U.S.D.A. 427.
- Robilarda**, new taxonomy in genus, 52.
- Rock garden plants**, germination and growth, 217.
- Rocky Mountain spotted fever**—
carrier in central and eastern States, control, U.S.D.A. 242.
rickettsiae, developing chick embryo as medium for growing, 277.
- Rodents**—see also Mice and Rats.
control, Hawaii 671, Ind. 672, Ohio 515.
relation to sugarcane growing, 812.
- Rodolia cardinalis*, see Vedula.
- Roentgen rays**, see X-ray.
- Roofs**, sheet stel, temperatures under, 720.
- Root**—
cell increase, relation to sulfhydryl, 489.
growth, effect of thiamin, 23.
hairs, cell polarity and differentiation of, 488.
knot, Fla. 221.
knot nematode—
attractiveness of roots and excised shoot tissues to, 537.
breeding crops for resistance to, 65.
control, Tex. 51, 52.
control on tobacco, Ga.Coastal Plain 378.
in San Joaquin Valley, 654.
injury restricted by a fungus, 666.
on cotton and tomatoes, 654.
on sweetpotatoes, tobacco, and clovers, U.S.D.A. 220.
on tomatoes, Ind. 656.

Root—Continued.

knot nematode—continued.

on tomatoes, relation to Indiana
canning crop, Ind. 386.

resistance in beans, nature of, 229
nodule bacteria, growth factor require-
ments, 182.

rot, barriers to prevent spread of, Tex.
50.

rot fungi, control by soil treatment with
chemicals, 654.

rot fungi of citrus and other woody
plants, Fla. 221.

rot studies, sorghum as aid in control,
Tex. 52.

temperature, effects in nutrient solution,
Mass. 491.

tips, excised, growth, effect of tempera-
ture, 25.

tips, excised, one-millimeter length,
growth behavior, 349.

vegetables, household storage, 593.

Roots—

auxin production in, 491.

growth, inhibition by auxins, 769.

Rose—

black mold and storage dieback, Oreg. 50.

black spot, Tex. 51.

black spot and dieback, field control, Tex.
51.

black spot fungus spores, viability, Tex.
51.

diseases, studies, Tex. 51.

downy mildew in British Columbia, 802.

fungicides, spreader materials for, Tex.
51.

leaf beetle, Pa. 68.

plants, handling and storage, Oreg. 41.

powdery mildew, 53.

powdery mildew, effect of temperature
and relative humidity, [N.Y.]Cornell
667.

stocks, breeding and testing, Iowa 40.

stocks, hardy, thornless, genetics, S.Dak.
210.

Rosellinia bunodes on coffee roots, PR.Col.
527.

Roses—

boron deficiency in, symptoms, 802.

breeding, S.Dak. 210, Tex. 41.

common beetles on, N.J. 550.

culture, Tex. 41.

fungicides for, 233.

gravel culture in greenhouse, Ohio 519.

Rosin, liquid, list of references to literature
on, U.S.D.A. 10.

Rotation—

and manure experiments, Nebr. 17.

of crops, 16, Alaska 362, Idaho 203, Ind.
639 773, La. 639, N.Mex. 775, Nebr.
639, R.I. 775, Tex. 37, Wash. 201.

Wyo. 503.

of crops, fertilized and limed, Ky. 501.

of crops, fertilizer experiments, Tex. 37.

Rotenone—

alkaline carriers injurious to, Wis. 541.

fly sprays, terpene ethers in, Del. 675.

Rotenone—Continued.

in derris and cube, determination, 814.
in solution, effect of solvent, West.Wash.
391.

Rotylenchus multiincatus, attractiveness of
roots and excised shoot tissues to, 537.

Roughages—

comparison and relation to grain in dairy
cow rations, Iowa 95.

comparison for wintering steer calves,
Okla. 85.

efficient production and usage Miss. 825.
for fattening steers, comparison, Pa. 86.

maximum use in fattening cattle, Tex. 86.
moisture in, determination, 166.

Roundworms—

in swine, S.C. 103.

of cattle and sheep, Calif. 273.

removal from sheep, use of phenothiazine
in, 715.

Rubber—

in agriculture, uses and possibilities,
117.

yielding plants, production, 211.

Rum, Jamaica, produced in Puerto Rico, P.R.
Col. 469.

Ruminants, infestation by strongylata, vital
differential diagnosis, 835.

Run-off—

and rainfall of New England 475.

notes, Iowa 115.

or soil blowing, prevention by various
methods of following, Wyo. 579.

Rural—

appraisal system, American, comparative
adjustments in, 728.

community buildings, organization and
uses, [N.Y.] Cornell 132.

community formation, criteria, 137.

community organization, diagnosing, 138.

community patterns of social participa-
tion, 137.

credit, see Agricultural credit.

families of South, consumer problems,
886.

households, composition, [N.Y.]Cornell
136.

housing problems in South, 139.

labor, see Agricultural labor.

leadership, building, U.S.D.A. 139.

life, guide to literature, 300.

life problems focused by the depression,
133.

people, interests as portrayed in weekly
newspapers, Mich. 732.

planning, social-economic, 727.

population—

cityward movement, Okla. 132.

marginal, of Virginia, 730.

movement to and from farms in
Iowa, Iowa 132.

problem, Catholic, in America, 447.

property, appraisal, 725.

psychology, bibliography of, U.S.D.A.
444.

youth, future of, 138.

Rural—Continued.

- youth in farm organization and other national agency programs, 731.
- youth, out-of-school, in Pennsylvania, Pa. 297.
- youth, situation and prospects, 297.
- youth, situations and problems, status of research pertaining to, 138.
- youth speak, 731.
- zoning and agricultural zoning, 446.
- zoning as means of improving land use. U.S.D.A. 446.
- zoning, fundamentals, U.S.D.A. 446.

Rust hyphae and haustoria in unsectioned leaf tissue, demonstrating, improved technique for, 47.

Rutabagas, *see* Swedes.

Rutgers University, notes, 320.

Rye—

- breeding, N.Y.Cornell 34.
- cover crop, supplementing with fertilizers, N.Y.State 211.
- genetic studies, [N.Y.]Cornell 34.
- laxative principle in, isolation, Wyo. 554.
- prices, index number, N.Dak. 181.
- seed disinfection, N.Dak. 225.
- support crop, West.Wash. 363.
- variety tests, Fla. 200, Ga.Coastal Plain 363, Ind. 773, Wash. 201.

Ryegrass—

- and timothy, comparative resistance to Wisconsin winters, Wis. 502.
- Italian, nurseries for improvement, West.Wash. 363.

Sables, inheritance of color and pattern variability in, 772.

Saccharomyces ellipsoideus, heat resistance studies, 764.

Saissetia oleae, *see* Black scale.

Salmon—

- canned, spoilage in, evaluation, 8.
- poisoning in dogs, immunity following treatment with sulfanilamide, 577.
- poisoning in dogs, sulfanilamide as treatment, 424.

Salmonella—

- abortus equi*, phase variation in, 845.
- cholerae-suis kunsendorf* and swine dysentery, 715.
- enteritidis dublin* in pyosepticemia of calves, 837.
- food poisoning, infection or intoxication, 304.
- pullorum*—*see also* Pullorum disease.
- in species other than chicken, 847.
- viability, Mass. 569.
- spp., efficiency of aniline dyes against, 708.
- types, monophasic nonspecific, 418.
- types, new, from fowls, 285.
- typhi*, reversibility of alpha and beta phases, 710.
- typhimurium*—

and *Trichomonas columbae*, isolation from diseased pigeons, 286.

Salmonella—Continued.

typhimurium—continued.

- biochemical and serological varieties, 277.
- mortality in ducks due to, 847.
- Salt absorption and respiration, electrochemical theory, 629.
- Saltbush, use in rotation, 173.
- Salts—
- and nitrates, movement in Big Horn River, Wyo. 479.
- Wolman, toxicity, leaching and fire-retarding effectiveness, U.S.D.A. 117.

Sand—

- cultures, sterile, controlling pH of nutrient solutions in, 341.
- flies, salt-marsh, pyrethrum and oils for protection against, 250.
- fly in Florida salt-water marshes, experimental diking for control, 549.
- hill area, range survey in, Nebr. 640.
- Sandy loams, studies, 343.

Sanguinaria canadensis, alkaloids from, effect on growth of *Phymatotrichum omnivorum*, 657.

Santonin, analytical methods and collaborative studies on, 6.

Saperda tridentata, *see* Elm borer.

Saprogen, saprogenic, and saprogenicity, new terms proposed, 222.

Sarcophaga—

- aldrichi*, parasite of forest tent caterpillar, 684.
- n.spp., notes, 820.
- Sarcophaginae and miltoigrammatinae, natural grouping of species, 809.
- Sarivellia flavescens*, poisonous to livestock, Tex. 104.

Sauerkraut—

- health value, 593.
- home-made, in sealed fruit jars, keeping quality and vitamin C in, Wis. 141.
- vitamin C in 882.
- Sausage, slimy, yeast from, 303.

Sawdust—

- moisture determination in, Minn. 473.
- rate of decomposition, Mass. 477.
- Sawflies on conifers, Mich. 253.
- Sawfly, Abbott's, control, Mich. 253.
- Scabies, hypo-HCl method of treatment, 710.
- Scale—

- black, dead and live, fixation method for distinguishing on citrus, 670.
- black, on citrus, toxicity of dinitro-o-cyclohexylphenol to, 676.
- black, parasite with promising qualities, 287.
- control on citrus in Union of South Africa, 395.
- control with dormant sprays, Wash. 239.
- green, of coffee, 393.
- in citrus groves, fall clean-up measures against, 240.
- insect in Hungary, 395.
- insects in British Columbia, 672.
- insects in South Africa and host plants, 395.

Scale—Continued.

- insects on citrus, control, 809, Calif. 238.
- insects on citrus, ideal spray emulsion for, 809.
- insects on citrus, oil application for, methods, 817.
- present status and control 239
- soft, 392.
- species in tea regions, 392.

Scales—

- red and black, new parasites for, Calif. 238.
- status and control, 874.

Scelio fulgidus, egg parasite of plague grasshopper, 73.

Schiffnerula paraparenensis n sp., notes, 193.

Schistocerca gregaria—

- notes, 394, 810.
- rate of growth and size, 810.
- soil moisture and incubation period, 809.

Schistosomatum from muskrat, 105.

Schistosomes species of domesticated animals in India and their molluscan hosts, 710.

Schizomycetes, key for identification, 459.

Schizonotus sieboldi, parasite of imported willow leaf beetle, 551.

Schizotomiasis in muskrats, 849.

Schoenobius incertellus, spring brood larvae, 396.

School areas, rural, analytical study, S.C. 860.

Schools, effect of Wisconsin system of State aid on farm property taxes, Wis. 123.

Science and civilization, 445.

Scirpophaga sp.—

- notes, 82, 810.
- sp., parasite of, 811.

Scirtothrips—

- citri*, see Citrus thrips.
- signipennis* on bananas in Queensland, 394.

Sclerotinia—

- carunculoides*, notes, U.S.D.A. 655.
- fructicola* apothecia, destruction with calcium cyanamide, 231.
- fructicola*, notes, 534.
- sclerotiorum* ascospores, forced ejection of, 53.
- sclerotiorum*, notes, Fla. 221.
- spp., cause of brown rot of stone fruits, 60.
- stem blight on stocks in California, U.S.D.A. 48.
- trifoliorum*, notes, U.S.D.A. 220.

Sclerotium—

- delphinii*, notes, 02.
- rolfsii*, control on Dutch iris, Tex. 52.
- rolfsii*, notes, Fla. 221, Ga.Coastal Plain 378.
- rolfsii*, viability of sclerotia, Tex. 51.

Sclerotomes, free-living stages, lethal effects of nitrogenous chemicals, 711.

Scolothrips semmaculatus, notes, 245.

Scolytidae species from Mysore, 810.

Scolytus multistriatus, see Elm bark beetle, smaller European.

Screw worm—

- and fly repellents, Tex. 67.
- diphenylamine as wound protector against, U.S.D.A. 806.
- in cavies, development of immunity to, 550.
- natural foods, 539.
- oviposition stimulus, relation to pH of myiotic wounds, 418.
- volatile oils as ovicides for, 683.

Scurvy—

- cure in guinea pigs, amounts of vitamins for, Mass. 591.
- human, complement and ascorbic acid in, 455.
- in infants, treatment with crystalline vitamin C, 146.
- infantile, and vitamin C deficiency, 153
- subclinical, detecting and grading, 317.
- Scutigerella immaculata*, seasonal variation in distribution, 244.

Seed—

- importation, danger in, 796.
- protectants, tests, N.Y.State 222.
- supply, better, Miss. 774.
- testing service, certification and regulatory activities, Oreg. 35.
- treatments for cereals, N.Dak. 225.
- treatments for cereals, recent developments and future trends, U.S.D.A. 225.

Seedbed—

- preparation and cultivation, Idaho 720.
- preparation studies, Tex. 37.

Seed-corn maggot—

- notes, Tex. 67.
- on tobacco, Conn.[New Haven] 540.

Seedlings, effect of light fire, Miss. 787.

Seeds—

- certification in Germany, 225.
- disinfection, 182.
- fumigation, Fla. 238.
- germinated, selenium in, S.Dak. 273.
- germination—
 - effect of sterilization with calcium hypochlorite, 493.
 - in sand, tests, 377.
 - viability, and storage tests, Hawaii 638.

inspection, Ind. 209, Mass. 209, Me. 644, N.J. 511, N.Y.State 209.

oxygen respiration in, relation to freezable and unfreezable water, 181.

packeted, testing, Mass. 512.

production in Wisconsin, Wis. 123.

scarification with acid, machine facilitating, 378.

stored, insects infesting, Minn. 71.

treatment with auxin, aftereffects, 23.

vegetable, storage, 211.

weed, see Weed seeds.

Selection, relation to environment, 497.

Seleniferous areas, indicator plants for locating, 354, 634.

Selenium—

- affecting plant quality, Wyo. 569.
- forms, availability to crop plants, 344.

Selenium—Continued.

- in Maine feeding stuffs, Me. 90.
- in rocks, soils, and plants, S.Dak. 757
- reaction of *Astragalus* spp. to, 763
- toxicity studies, S.Dak. 273.

Semen—

- bull, exchange between England and Holland, 33.
- production of male fowls, 32.

S. miorhiza perovulgata, pest of Daincha, 811.*Senecio* spp.—

- alkaloids of, 275.
- poisonous to livestock, Tex. 104.

Septicemia, hemorrhagic—

- and transit fever, differences in clinical pictures, 419.
- bacterin and Bang's disease of cattle, 421.
- in cattle and swine, Fla. 273.
- in Indian buffaloes, 422.
- studies, S.Dak. 274.

Septoria—

- and *Macrosporium* leaf spots, varietal susceptibility of tomatoes, 654
- apit* pycnidium, number of spores in, 657.
- bromigena*, monosporous cultures, 381.
- new taxonomy in genus, 52.

Sequoa—

- gigantea*, embryo development, 185.
- sempervirens*, embryogeny and comparison of Sequoias, 347.

Sericulture, see Silkworm.

Sesame—

- culture experiments, Tex. 37.
- variety tests, Tex. 37.

- Spinach—
 - availability of calcium in, 307.
 - available iron in, 596.
 - fertilizer placement, Va. Truck 788.
 - Fusarium* disease, 47.
 - Fusarium* wilt, U.S.D.A. 795.
 - late, variety tests, R.I. 788.
 - photoperiodic response, effect of temperature, 765, [N.Y.] Cornell 42.
 - quality and yield, Tex. 41.
 - utilization of calcium in, 307.
 - white rust, 532.

- Spirillum ovis* infection in ewes, 574.
Spirochaeta recurrentis, longevity within the tick, 276.
Spiruracera new genus erection, 106, 391.
 Spittle bugs on strawberry, control, Oreg. 71.
Spodoptera mauritia—
 major pest of rice in Cochín, 811.
 studies, 810.
Sporocybe azuleae, notes, 388.
 Spotted fever, Rocky Mountain, value of vaccine from rickettsiae cultivated in embryonic chick tissues, 840.
 Spotted wilt in Missouri, U.S.D.A. 655.
 Spray—
 injury studies, 542, 671, Del. 221.
 materials and dusts, new, tests, Del. 221.
 materials, orchard, evaluating, 532.
 mixtures, standard, adhesives for, Conn. [New Haven] 540.
 residue and human health, 814.
 residue, digest of literature through 1934, U.S.D.A. 242.
 residue removal, Ind. 645, Wash. 230.
 residue removal from apples, effect of insect residues, 677.
 residue studies, 69, Mass. 540.
 Spraying—
 dormant season, of trees and shrubs, N.J. 542.
 experiences, 671.
 role of electrical charges produced during, 243.
 winter, of trees and shrubs, 815.
 Sprays—see also Fungicides, Insecticides, and specific forms.
 adhesiveness, determination, Pa. 50.
 copper, see Copper.
 deposit of, factors in, 242.
 dormant, on conifers, toxicity to insects, 543.
 dormant, problems in New York, 542.
 nonpoisonous, [N.Y.] Cornell 66.
 oil, see Oil sprays.
 safeners for use with calcium compounds, 507.
 Springtail, garden, notes, Conn. [New Haven] 540.
 Spruce needles, anatomy, 219.
 Spruce sawfly—
 European, outbreak in Canada and bionomics, 687.
 small, notes, 401.
 yellow-headed, in Maine, 553.
 Spurge, leafy, feeding value for sheep, 403.
 Squash—
 bug, Conn. [New Haven] 540.
 crookneck, *Pythium* root rot of, 531.
 diseases on New York market, U.S.D.A. 48.
 types, vegetative reproduction, 515.
 vine borer, 807, Mass. 540.
 Squashes—
 breeding, Conn. [New Haven] 512, N.Y. State 211.
 household storage, 593.
 Squashes—Continued.
 new, early, productive summer, Conn. [New Haven] 157.
 Squirrels—
 gray, and fox of east Texas, Tex. 66.
 gray, in southeastern Ohio, U.S.D.A. 669.
 hypophysectomized, sperm formation and growth of accessory reproductive organs after treatment with pregnancy urine, 499.
 susceptibility to virus of endemic typhus fever, 279.
 Stablefly—
 new method of feeding, 251.
 transmission of rinderpest by, 837.
 Stain schedules, new, use of Bismarck brown Y in, 763.
 Staining solutions included in National Formulary, 184.
 Stains—
 Biological, Commission on Standardization of, 763.
 recently certified, 184.
 standardization, progress in, 763.
 Stallions, enrollment in Indiana, Ind. 259.
 Staphylococci, pathogenic, 711.
Staphylococcus aureus—
 efficiency of aniline dyes against, 708.
 resistance to heat, 764.
 Starch—
 grain, growth of, 627.
 manufacture from farm products, fellowship for research in, 605.
 microscopy by Spierer lens, 470.
 production problems from potatoes, Me. 10.
 products, degradation by enzyme, Iowa 4.
 root, industry, possibility of, Iowa 167.
 Starches used in textile sizing, comparison. U.S.D.A. 460.
 Steam generator, instantaneous, for sterilizing dairy utensils on farm, 429.
 Steel fence posts, protective covering and life of, S. Dak. 287.
 Steel, use in farm buildings, Iowa 115.
 Steers—see also Cattle, beef.
 and heifers, relative rate and efficiency of gain, Wyo. 554.
 cottonseed meal-silage rations for, effect of additional fat, Tex. 87.
 cut-back yearling, returns secured from fattening on pasture, Idaho 688.
 determination of grades from weights and measurements, U.S.D.A. 557.
 fattening—
 cottonseed meal and hulls v. corn and alfalfa hay, S. C. 86.
 experiments, Ga. Coastal Plain 404, Nebr. 689.
 rations, Ky. 553.
 rations, local feeds in, Hawaii 687.
 reducing corn and increasing hay for, 402, Ohio 558.
 roughages for, comparison, Pa. 86.
 feeder, relative efficiency of gains in Good, Medium, and Common, Pa. 86.

Steers—Continued.

- grazing, forage consumed by, amount, Ill. 692.
- grazing on good pasture, value of cottonseed meal or cake for, Miss. 825.
- mixed-protein v. single-protein concentrates for, Ind. 688.
- rations, economy of adding protein concentrates to, Idaho 688.
- stocker, sorghum silage v. rye pasture for wintering, S.C. 86.
- wintering, cheapest available sources of concentrates for, Okla. 85.
- wintering on different planes of nutrition, U.S.D.A. 258.

Stemphylium, *Macrosporium*, and *Alternaria*, comparative pathogenicity and taxonomy, Fla. 221.

Stenobracon nicevillei, studies, 810.

Stephanoderes hampei—

- in Ceylon, 400.
- in dry cotton fruit stalks and carpels, 810.

Stereum gausapatum, growth and variability in culture, 390.

Sterility, combating with hormones, 497.

Sterols, production of derivatives of, role in nutrition, Iowa 84.

Stichorchis subtriquetrus, precercarial development, 105.

Stillingia oil, American and Chinese, composition, 324.

Stinkbug—

- pear, in Tsingtao, 393.
- rice, local migration, 544.
- southern green, natural enemies in Haiti, 391.
- southern green, on papaw, 393.
- spined, notes, Conn.[New Haven] 540.

Stock, *see* Livestock.

Stock foods, *see* Feeding stuffs.

Stock (plant)—

- bacterial blight, Calif. 221.
- bacterial disease, U.S.D.A. 48.
- mosaic diseases, 63.

Stockyards fever, *see* Septicemia, hemorrhagic.

Stomach and intestines, role in phospholipid metabolism, 88.

Stomach worms—

- in Indian domestic ducks, 837.
- of pigs in North Queensland, 111.
- of pigs in South, effectiveness of sanitation system, 570.
- of sheep, Calif. 273.
- of sheep and goats, Tex. 104.
- of sheep, control in eastern Canada, 715.
- of sheep, effect of repeated treatment, 110.
- of sheep, treatment with copper sulfate, Miss. 834.
- two spirurid, in fowls, 837.

Stomata—

- in *Coffea*, relation to chromosome number, 765.
- number, factors affecting, 181.

Stomatitis, vesicular, virus, propagation in chick embryo, 577.

Stomoxys calcitrans, *see* Stablefly.

Stone pickers, improvements in, Pa. 115.

Stoves—

- brooder types, comparative efficiency, Fla. 255.
- gas, types for domestic use, Nebr. 749.
- kerosene, buying and using, 750.
- kerosene, performance analysis of selected types, Me. 750.

Strangles, outbreak in cavalry horses, Neo-Prontosil for, 846.

Stratosphere, lower, structure of, 11.

Strawberries—

- breeding, Calif. 210, Tex. 41, Wash. 211, West.Wash. 374.
- culture, Miss. 787.
- fertilizer and cultural requirements, La. 645.
- fruit bud formation in, Mass. 512.
- hardiness in, Minn. 215.
- handling and shipping without refrigeration, U.S.D.A. 216.
- Howard 17, response to sodium salts, N.H. 650.
- irrigation and fertilization, Okla. 40.
- mulching, La. 645.
- Northstar, origin and characteristics, U.S.D.A. 44.
- nutrient needs, N.Y.State 213.
- production, profits in, Mich. 216.
- root and crown development, 792.
- spacing and mulching, R.I. 787.
- varieties and soil management, Iowa 40.
- varieties, comparative transpiration rates, Okla. 40.
- variety tests, Ga.Coastal Plain 374.
- yields and plant production, effect of lime on, La. 645.

Strawberry—

- aphid, control, 809, Oreg. 71.
- aphid, notes, 69.
- chlorosis, control, Tex. 51.
- crown borer, biology and control, Ky. 540.
- crown borer, morphology, biology, natural enemies, and control, Ky. 81.
- crown miner, control, Oreg. 71.
- crown moth, control, Oreg. 71.
- diseases, La. 656, Oreg. 61.
- diseases affecting foliage, 801.
- diseases in New York State in 1938, 231.
- fields, stem nematode in, U.S.D.A. 635.
- fruitworm, control, Oreg. 71.
- fruitworm on flax, rotation control, Oreg. 68.
- insects, control, U.S.D.A. 806.
- leaf roller, biology and control, 806.
- leaf roller, control, Oreg. 71, Wis. 541.
- leaf roller, western, control, Oreg. 71.
- red core disease, U.S.D.A. 525.
- red stele disease, 232, 534, U.S.D.A. 378, 795.
- root weevil, control, Oreg. 71.
- weevil, control, U.S.D.A. 806.

Strawberry—Continued.

- weevil, Japanese, activity, 552.
- yellow resistant Blakemore variety, 534.

Stream flow—

- measurements in Ohio River Basin, 850.
- relation to precipitation on Salt River watershed above Roosevelt Dam, Ariz. 580.

Streptococci—

- beta hemolytic, in vitro, bactericidal effect of sulfanilamide, 420.
- classification in bovine mastitis, 702.
- contamination of drinking glasses by, 602.
- group-B, antibodies in sera of cows infected with, 713.

hemolytic—

- human, bacteriostatic action of sulfanilamide on, 274.
- in tonsils of children, relation to vitamin C of tonsils and blood, 151.

- infections in mice, combined serum and sulfanilamide in treatment, 277.
- strains, serological and biochemical properties, 277.

- in milk, metabolic studies, Pa. 97.
- in swimming pool water, Mass. 469.

lactic acid—

- gas production by, 567.
- maintenance of acid-producing activity in cultures, 568.
- of cheese starters, 702.

- nonhemolytic, that ferment aesculin, significance in mastitis, 421.

- of bovine mastitis, agglutinability, 421.
- of mastitis, effect of sulfanilamide treatment, 420.

- udder, of dairy herds, 419.

Streptococcal infections of udder, effect of sulfanilamide, 108.**Streptococcus—**

- agalactiae*, group-B, capsulation, diffusion factor, and serological behavior, 108.

- agalactiae*, rapid identification, 839.

- hemolyticus*, mode of action of sulfanilamide on, 572.

- lactis* in mastitis milk, growth responses, 702.

- pyogenes*, production of agglutinins for, effect of thyroid activity, 274.

- zymogenes* in intestines of animals, 414.

Strip cropping—

- in southwestern Pennsylvania, Pa. 840.
- studies, Tex. 14.

Stromatium fulcum* on valuable furniture in Egypt, control, 80.*Strongylids of horses, anthelmintic value of oil of terebentine and carbon bisulfide, 835.****Strongylid larvae, longevity in pastures, 278.*****Strongyloides*—**

- canis* occurring naturally in dogs, distinct from human species, 577.
- life cycle, 835.

***Strongyloides*—Continued.**

- ratti*, artificial acquired immunity to, specificity, 105, 278.

- ratti*, constitutionally dissimilar lines, 105.

- species of domestic animals, anatomy and morphology, 835.

Strongyloidosis of livestock, control, 835.**Strongylosis of horse, vital differential diagnosis, 836.*****Strongylus*—**

- spp. in horses, *n*-butyl chloride treatment, 428.

- spp., rate of egg production, 106.

- vulgaris* in horses and reaction of infested ceca, 717.

- vulgaris*, studies, 846.

Strophostyles helvola*, habits and value on eroded areas, 371.*Strychnine, detection in carcasses and corpses, 274.****Stumpage and log prices for 1937, U.S.D.A. 47.****Subsoils, dense orchard, pore space unoccupied by water in, capillary tension as measure, 478.*****Subulura brumpti*, life history, 578.*****Suckleya suckleyana*—**

- chemical composition, 132.

- poisonous to livestock, 107.

Sucrose—

- inversion in harvested sugarcane, resistance to, 783.

- synthesis in leaves, 766.

Sudan grass—

- breeding, Calif. 199, Tex. 37.

- breeding for reduced HCN content, Wis. 502.

- crossed with sorghum, danger from hydrocyanic acid poisoning, 417.

- culture experiments, Tex. 37.

- pasture for pigs, value, Nebr. 689.

- production of tetraploid strains, [N.Y.] Cornell 84.

- productive varieties or strains, Calif. 200.

Sugar—

- beet, cost of production by three companies, Wis. 123.

- corn, industrial uses, Iowa 166.

- corn, value in grain ration of dairy calves, Iowa 95.

- house products, ash in, conductimetric determination, 758.

- in plant juices and tissues scales method for determination, 7.

- industry, Mauritius, byproducts, 758.

- industry, papers on, 758.

- industry, protecting from losses due to hurricanes, 334.

- manufacture, clarification in, papers on, 758.

- manufacture, improvements in Mauritius, 759.

- mills, colloids in, classes of, 331.

- quality, effect of sirup composition, 758.

Sugar—Continued.

- reducing, determination, new method, 753.
- refining for American market, 758.
- structure and composition, 142.
- wood, liquor, fermentation, Wis. 4.

Sugar beet—

- byproducts in lamb fattening rations, S.Dak. 255.
- Cercospora* leaf spot, pathogenicity and control, Iowa 48.
- curly top, N.Mex. 795.
- curly-top-resistant varieties, U.S.D.A. 58.
- diseases, etiology and control, Wash. 222.
- farms, costs per acre, labor used, etc., Wis. 123.
- leafhopper, *see* Beet leafhopper.
- machinery, development, Calif. 287.
- seed, annual production, N.Mex. 775.
- seed, treatment for damping-off, Calif. 221.
- thrips, biology, habits, and distribution, Calif. 245.
- vascular rhizoctonosis of, 47.

Sugar beets—

- breeding for disease resistance, Iowa 48.
- cultural, nutritional, and rotation experiments, Calif. 199.
- culture experiments, Wash. 201, Wyo. 503.
- damping-off tests, quasi-factorial v. randomized-block designs of experiments, 662.
- effect of manure and alfalfa on, Nebr. 639.
- fertilizer experiments, Calif. 199, Nebr. 363, N.Mex. 775, Oreg. 35, Wash. 201, Wyo. 503.
- in wireworm-infested fields, remedy for, 400.
- planting tests, Nebr. 639.
- rotation experiments with, Nebr. 363.
- storage in high humidity and low temperature, 370.
- sugar production and storage in, Iowa 34.
- tetraploid, production by use of colchicine, 496.
- translocation of carbohydrates in, 350.
- variety tests, N.Mex. 775, Wash. 201.
- vascular rhizoctonosis, 526.

Sugarcane—

- alpha cellulose important byproduct from, P.R.Col. 469.
- availability of insoluble phosphates to, 370.
- bagasse and foliage, alpha cellulose from, 330.
- beetle in Louisiana, 812.
- behavior to length of day, 190.
- borer at government farm, Jorhat, 811.
- borer, biological control in Puerto Rico, 547.
- borer, control, P.R.Col. 541.
- borer control, papers on, 812, 818.
- borer, larval dispersion, 76.

Sugarcane—Continued.

- borer on rice, La. 674.
- borer parasites, introduction in Louisiana, 694.
- breeding, Fla. 200, P.R.Col. 502.
- croses, susceptibility to sugarcane borer injury, 812.
- culture, 732, 783.
- Cytospora* rot, 228.
- diseases, P.R.Col. 527.
- diseases, control in Florida, 228.
- diseases in Brazil, 228.
- diseases in Hawaii, 385.
- diseases in Philippines, 228.
- diseases in United States, 228.
- diseases, minor, in Egypt, 228.
- drought resistance in, 753.
- dry top rot disease, 229.
- dwarf or multiple bud disease, 228.
- effect of length of day, 783.
- entry into United States, quarantine restrictions on, 813.
- experiments, P.R.Col. 502.
- factory data, reporting, uniformity in, 758.
- factory operations, graphic critique, 758.
- fertilizer experiments, 793, P.R.Col. 502.
- Tex. 87.
- fertilizer for, Miss. 774.
- Fiji disease, behavior of P.O.J. 2873 variety toward, 353.
- Fiji disease in Philippines, 228.
- Fiji mosaic disease, transmission experiments, 816.
- floral characters in, 782.
- gaps in rows and effect on yield, U.S.D.A. 508.
- growth, effects of delayed weed control, pictorial showing, 370.
- gumming disease resistance, breeding and testing seedlings for, 227.
- history, 208.
- industry of Louisiana's Sugar Bowl, depression in, effect, 135.
- industry, papers, 782, 783.
- insects, 240.
- insects and control, 672.
- insects and rodents, papers, 812.
- juice as yeast nutrient medium, 758.
- juice, composition, papers, 782.
- juice, sulfate in, determination, 759.
- leaves, folding of, 892.
- mechanical harvesting, 782.
- mosaic—
 - behavior on certain soils, 228.
 - comparison in different countries, 228.
 - control, 228, La. 530.
 - from different countries, comparison, 385.
 - 385.
 - immunity studies, 228.
 - insect vectors, 812.
 - resistance, breeding and testing seedlings for, 227.
 - strains of virus, 228.

- Sugarcane—Continued
 mosaic—continued.
 transmission by aphids, 816.
 variety-resistance tests against
 P.R.Col. 527.
 P.R.Col. 527.
 pathology, developments in, 227.
 P.O.J. 2878, behavior, relation to Fiji
 disease and transmission of virus, 816.
 pests in Jullundur circle, combating 811.
 physiology of blooming, Fla. 200.
 Pythium root rot in Louisiana, 797.
 rates of applying potassium to, test, ex-
 perimental technic, 370.
 red rot and *Pythium* root rot, 223.
 red stripe, in Brazil, 228.
 research, crossing-lantern used in, 782.
 Rhizoctonia disease, 228.
 ripening, relation to water supply, 766.
 root rot, factors affecting, 228.
 rootstock weevil, biology and importance
 in Louisiana, 812.
 saw grass, bare soil, and mulched ground,
 evaporation and transpiration from,
 Fla. 287.
 sclerotic disease, 228.
 shocked, pasture, and sugarcane silage
 for wintering cattle, comparison, Fla.
 254.
 soils, papers, 782.
 stem galls induced with insect extract,
 228, 812.
 streak disease in Louisiana, 530.
 surface irrigation, Fla. 287.
 Technologists, International Society,
 proceedings, papers, 781.
 value for forage and other purposes,
 composition factors, Fla. 200.
 varieties, cell-sap concentration, relation
 to resistance to white leaf louse, 812.
 varieties, papers, 782, 783.
 variety tests, 783, S.C. 36, Fla. 200, La.
 639, P.R.Col. 502, Tex. 36.
 variety tests, border competition in, 782.
 weevil, New Guinea, notes, 401.
 weighing apparatus, 782.
 white moth borer, parasite of, 82, 810,
 811.
 yellow aphid, control, P.R.Col. 541.
- Sugars—see also Glucose, Lactose, Sucrose,
 etc.
 in plant materials, determination, 329.
 reducing, heat sterilized, effect on
 thermal resistance of bacteria, 764.
- Sulfanilamide—
 concentration in blood and milk of cattle,
 108.
 in equine therapy, experimental use, 422.
 in milk, estimation, 9.
 mode of action, 572.
 pharmacology of, 838.

- starch, manufacture in United States, 473.
- weevil, control, seed treatment for, new method, 686.
- weevil in Louisiana, control, 552.
- weevil, West Indian, life history in Barbados, 80.
- wilt, control, Del. 221.

Sweetpotatoes—

- baking tests, Hawaii 638.
- breeding, 508, Iowa 33.
- care in handling, Miss. 774.
- culture, Miss. 774.
- curing and storing, new ideal in, Miss. 774.
- curing studies, Okla. 35.
- date of planting and plant bed experiments, N.Mex. 775.
- fertilizer and liming studies, La. 639.
- fertilizer and propagation tests, Iowa 34.
- fertilizer experiments, 508, Conn.[New Haven] 501, La. 639, S.C. 36.
- fertilizer formulas and carriers of elements, Ga.Coastal Plain 363.
- growth and yield, effect of lime and calcium chloride, 509.
- harvesting, Miss. 850.
- hogging off, returns from, Ga.Coastal Plain 404.
- household storage, 593.
- marketing, storage problems in, Ind. 720.
- nitrogen and potassium top dressings for, Ga.Coastal Plain 363.
- plant production tests, La. 639.
- Porto Rico, nutrient deficiency symptoms of, 797.
- production in Yazoo-Mississippi Delta, Miss. 643.

Sweetpotatoes—Continued.

- production of starch free from yellow color from, Iowa 167.
- ratios of organic:nonorganic nitrogen, Ga.Coastal Plain 363.
- spacing experiments, Hawaii 638, La. 639.
- storage quality, Iowa 34.
- storage quality, relation to curing temperature, 509.
- Triumph, effect of nitrogen on grade and shape, 509.
- use in dairy rations, La. 700.
- varieties, effect of grazing by dairy cattle on production, La. 639.
- variety tests, Ga.Coastal Plain 363, Hawaii 633, Iowa 33, La. 639, Okla. 35, P.R.Col. 502, S.C. 36.
- yields from vine cuttings v. sprouts of same parentage, S.C. 36.

Swellhead—

- of sheep and goats, Tex. 104.
- of turkeys, Calif. 273.

Swimming pool water, streptococci in, Mass. 469.

Swine—see also Pigs and Sows.

- breeding stock, evaluation, Iowa 84.
- dysentery and *Salmonella*, 715.
- erysipelas in turkeys, 578.
- erysipelas, nature of certain phases and prevention, Nebr. 708.
- hard liver disease, Wash. 274.
- inbreeding, effect, Okla. 85.
- influenza, 707.
- influenza, antibody response to, 282.
- influenza virus, intermediate host for, 715.
- influenza viruses, serological studies, 844.
- legless, new lethal, 192.
- parasites in, Hawaii 671.
- reproduction, relation to vitamin E, Iowa 84.
- tonsillar tissue, acid-fast micro-organism present in, 834.
- vertebrae, variations in number, 357.
- virus diseases of, 570.
- reproduction, relation to vitamin E,

Sylvatic plague, epidemiology, role of birds in, 104, 840.

Symphylella—

- n.spp. from California, descriptions, 815.
- subterranea*, seasonal variation in distribution, 244.

Symphyliid—

- garden, 807.
- of vegetables and flowers, control, Oreg. 68.

Synanthedon—

- bibionipennis*, notes, Oreg. 71.
- rutlani*, see Strawberry crown moth.

Syngamus trachea—

- domestic fowls as carriers, 104.
- flies as intermediate hosts, 682.

Synnema lynosyrana, outbreak, 77.*Synthetocaulus* parasitic in sheep, 835.*Syrphus* spp., biology, morphology, and anatomy, 820.

- Systasis dasyneuræ* n.sp., biology and morphology, 823.
- Tabanidae of Delaware, Del. 238.
- Tachycines asynamorus*, notes, 870.
- Tachypterellus quadrigibbus*, see Apple curculio.
- Taenia**—
- piliformis*, resistance of rabbits to, 849.
- taeniaeformis* larvae, cultivation in vitro, 106.
- Taenias from large wild carnivores, 274.
- Taeniothrips**—
- inconsequens*, see Pear thrips.
- simples*, see Gladiolus thrips.
- Tall oil, list of references to literature on, U.S.D.A. 10.
- Tanalth, toxicity, leaching, and fire-retarding effectiveness, U.S.D.A. 117.
- Tangerine diseases on New York market, U.S.D.A. 48.
- Tankage as supplement for fattening beef calves, S.Dak. 828.
- Tannin in leaves of *Lespedeza sericea*, 5.
- Tapeworm**—
- anoplocephalid, from a domestic pigeon, 837.
- broad, action of albuminous and lipoidal substances on blood of experimental animals, 836.
- effect on growing chickens, 104.
- from herring gull, life cycle, 105.
- hawk, producing a proliferating *Cysticercus* in mice, 105.
- infections, premunition in, nature of, 710.
- of Indian dogs and cats, life history, 837.
- of sheep in Leningrad region, 835.
- poultry, effect on weights of growing chickens, 112.
- poultry, in Hawaii, life history, 577.
- poultry, new intermediate hosts of, 105.
- removal from dogs, tests of isoamyl-o-cresol for, 718.
- studies, 106.
- susceptibility of poultry to infection, 285.
- transmission by garden slugs, West. Wash. 424.
- Taphrina**—
- carveri* n.sp. on silver maple, 390.
- dearnessii* n.sp. on red maple, 390.
- genus in North America, 53.
- Taraxacum laevigatum* f. *scapifolium*, new name, 621.
- Tariff**—
- rates on items entering farm production and living costs, Iowa 120.
- research committee of Wisconsin, economic theory discussions, 290.
- Tarnished plant bug**—
- as apple pest, 544.
- control, 807.
- notes, Conn. [New Haven] 540, Ind. 671.
- relation to alfalfa seed production, Utah 74.
- Taro**—
- seeds, germination and seedling development, 371.
- soft rot and vascular necrosis, Hawaii 655.
- utilization of calcium in, by human subjects and rats, Hawaii 736.
- waste, feed for fattening broilers, Hawaii 29.
- Tarsoneminae** of North America, revision, U.S.D.A. 82.
- Tarsonemus**—
- latus*, see Broad mite.
- pallidus*, see Cyclamen mite.
- Tax**—
- delinquency, amount on real estate, S.C. 122.
- exemptions, homestead, expected effects, S.C. 122.
- payments of farm families on relief, W.Va. 182.
- reverted lands in Lake States, 481.
- Taxation**—
- and ability to pay, S.C. 122.
- national and local, in rural areas, 854.
- Taxes**—
- farm, relation to oil property taxation in Kansas, Kans. 291.
- real estate, trends, S.C. 122.
- Taxonomy and floristics** of the Americas, 621.
- Tea, structure and composition, 142.
- Teak, notes, 211.
- Tear gas, World War, new use for, 224.
- Teeth**—
- decay and vitamins, 310.
- decay, relation to nutrition, 600.
- decay, relation to vitamin D and mineral deficiencies, 590.
- mottled enamel of in South Dakota, 747.
- mottled enamel of, inversely proportional to dental caries, 154.
- Telenomus ullyetti*, egg parasite of bollworm, 76.
- Temperature**—see also Climate.
- and precipitation during February 1939, U.S.D.A. 12.
- as factor in surface-energy relations, Hawaii 617.
- changes conditioned by radiation in upper troposphere in anticyclone regions, 615.
- changes in soils, rate of, Hawaii 617.
- chart, new, 615.
- lapse rate in lowest hundred meters of atmosphere, 615.
- Tenebrio molitor*, see Mealworm, yellow.
- Tennessee**—
- human and physical resources, 137, 138, 298, 584.
- Valley area, agricultural publications applicable to, U.S.D.A. 819.
- Tent caterpillar**—
- forest, parasite of, 684.
- Great Basin, biology, 546.
- Teosinte, production of tetraploid strains, [N.Y.] Cornell 34.
- Termite shields, metal, construction, 544.

Termites—

- common and dry-wood, in Puerto Rico, P.R.Col. 244.
- control, 807, Conn.[New Haven] 540.
- control, value of an adherent gas in, 892.
- damage to buildings in Jamaica, 544.
- dry-wood, P.R.Col. 541.
- evaluating soil poisons for, 244.
- in banked citrus trees, control, 544.
- interrelation with vegetation and soils, 815.
- notes, 893.

Terrace outlets and farm drainageways, U.S.D.A. 851.

Terraces, subsurface drainage for, types, Okla. 115.

Terracing machine, two-way, design, development, and trial, Iowa 115.

Testicular extracts, stability, 500.

Testosterone—

- effect on pituitary and mammary gland, 773.

propionate—

- effect on genital tract of immature female rat, 30.
- effect on vaginal opening in immature rat, 31.
- gonadotropic action on immature mouse ovary, 31.
- injections in castrated rats, effect, 361.
- response of mammary gland of monkey to, 195.

Tetany, treatment with single massive dose of vitamin D, 745.

Tetranychus—

- pacifous*, notes, 539.
- sp., biology, 811.
- tetarius*, see Red spider.

Tetrastichus n.sp., hyperparasite of *Schizoonotus* pupae, 552.

Texas College, notes, 607.

Texas Station, notes, 607.

Texas Station, report, 157.

Textile—

- fabrics, labeling, adequacy for fiber content, 749.
- sizing, starches from different sources for, comparison, U.S.D.A. 460.

Textiles—see also Fabrics.

- and clothing, studies, Iowa 155.
- cooperative project in, 154.
- household, usage by farm families, S.C. 155.

Thallium injury to tobacco, and frenching, differentiation, 386.

Theelin, increased sensitivity of vagina of castrated rat induced by cotton swab procedure, 362.

Theileriasis, bovine, 837.

Theobaldia spp. in Owens Valley, California, 681.*Theresa claripalpis*, introduction into Cuba and artificial multiplication, 813.

Thermoregulator, simple mechanical, description, 493.

Thiamin—see also Vitamin B₁

- effect on root growth, 23.
- effect on synthesis of body fat in pigeons, 877.

requirements of dogs, effect of composition of diet, 576.

requirements of rats, relation to dietary fat, 876.

role in plant growth, 189.

synthetic crystalline, curve of response to for vitamin B₁ assay of foods, 875.*Thielavia basicola*, relation to necrotic virus of tobacco, 531.*Thielaviopsis basicola* on geranium, U.S.D.A. 48.

Thistle—

- Canada, control, Oreg. 35.

Canada, killing out with home-made subsurface shaver and use of duck-foot cultivator, Ind. 720.

Russian, composition, 485.

Thomomys annulata, parasite of ruffed grouse, Mich. 805.

Thrips—

- California toyon, biology, habits, and distribution, Calif. 245.

collected on Long Island, 678.

control, Calif. 238.

control under glass, 807.

notes, Tex. 66.

of economic importance in California, Calif. 245.

six-spotted, 245.

tabaci, see Onion thrips.

Thymus, intraperitoneal injection, effect on young rats, Conn.[New Haven] 594.

Thyroxine, effect on milk production and butterfat production, 702.

Thysanoptera—

- new, from Florida, 678.

new species in New Jersey, descriptions, 678.

Tick—

- fever of dogs and Lahore canine fever, relation, 718.

new, from Texas and Mexico with key to genus, 687.

Pacific coast, in United States, 687.

pests of Scotland, 809.

winter, in United States, 687.

winter, notes, Tex. 67.

Ticks—

- acquired immunity to, 105, 276, 572.

as vectors of animal diseases, 553.

filter-passing infectious agent isolated from, 276.

Indian species, diseases transmitted by and control, 711, 810.

infesting domestic animals in Southern Rhodesia, 402.

natural infection with *Spirochasta recurrentis*, longevity, 276.

new species from marmots, 275.

of Brazil, 83.

of domestic animals in Britain, 711.

Tillage—

and soil moisture studies, Wash. 201.
tools, mechanics of, Pa. 115.

Tilletia spp., susceptibility of forage grasses to, 657.

Tilletia tritici, see host plants.

Timber—see also Lumber and Wood.

destruction by marine organisms of Brisbane, 394.

industry, development in Tennessee and United States, Tenn. 653.

preservation against powder-post borer, 686.

species, estimating growth, Iowa 45.

wind-thrown, prevention of insect damage to, U.S.D.A. 242.

Timothy—

alsike-sweetclover as hay mixture, merits, Wis. 502.

and ryegrass, comparative resistance to Wisconsin winters, Wis. 502.

breeding, Iowa 33.

culture, Ohio 783.

cut at progressive stages of growth, protein in, [N.Y.] Cornell 34.

cuttings, rooting, tests of plant hormones for, 363.

growth, relation to latitude, 208.

hay v. alfalfa hay for dairy cows, Va. 830.

nitrogen fertilization, [N.Y.] Cornell 34.

practices for growing and use, U.S.D.A. 203.

variety tests, Alaska 362.

Tin in soil fertility and plant nutrition, Oreg. 17.

Tineola bisselliella, see Clothes moth, webbing.

Tires, pneumatic, for agricultural equipment, life, service, and cost of service, Iowa 115.

Titanium, iron determination in presence of, 327.

Toad, giant—

as vector of helminth ova in Puerto Rico, 104.

food of in Trinidad and British Guiana, 670.

Toads of southeastern United States, 235.

Tobacco—

American, market in Netherlands, U.S.D.A. 726.

bacterial leaf spots, U.S.D.A. 525.

barn construction, requirements in, Ky. 584.

black root rot, Mass. 526.

black shank, Ga.Coastal Plain 378.

boron tests and fractional applications with, Ga.Coastal Plain 363.

breeding, Fla. 200, P.R.Col. 502, Wis. 502.

breeding for low nicotine, Ky. 501.

bright leaf, drying and curing, 785.

brown root rot, causes, 531.

brown root rot, nature of, 662.

budworm, notes, Conn.[New Haven] 540.

Tobacco—Continued.

Burley, nitrate level in soil under, effect on growth, Ky. 501.

chewing, mosaic-free barn-cured, Ky. 526.

cigar-leaf, fermentation during curing, microflora associated with, Pa. 36.

cigar-leaf, studies, Conn.[New Haven] 509.

curing by artificial heat, Wis. 502.

curly top, recovery from and acquired tolerance of, 662.

cutworm, life history notes, 396.

diseases, Conn.[New Haven] 526, 530, Fla. 222, U.S.D.A. 378, 525, 794.

downy mildew—

control, Ga.Coastal Plain 378.

control demonstrations, Fla. 221.

development, effect of temperature, 47.

in Brazil, 58.

in North Carolina, U.S.D.A. 48.

situation in Florida, U.S.D.A. 48.

studies, U.S.D.A. 220, 378, 525.

treatments, S.C. 50.

experiments, S.C. 36.

farm management, Va. 857.

farm prices, regional variations, Ky. 535.

fermentation, role of yeasts in, Conn. [New Haven] 501.

fertilizer experiments, Ky. 501, Pa. 36.

fertilizer formulas and carriers of elements, Ga.Coastal Plain 363.

fertilizer placement, Ga.Coastal Plain 363.

fla beetle, insecticide tests for control, S.C. 69.

flue-cured, black root rot of, relation to carbon dioxide evolution from soils, 654.

flue-cured, data for, Ga.Coastal Plain, 863.

frenching and thallium injury, differentiation, 386.

frenching, spectrographic analysis for study, 182.

frog-eye leaf spot, Ga.Coastal Plain 378.

Granville bacterial wilt, Ga.Coastal Plain 378.

growing in Canada, 371.

Havana Seed, time of harvesting, Conn. [New Haven] 510.

industry, economic aspects, U.S.D.A. 128.

industry in Puerto Rico, U.S.D.A. 293.

insects, Conn.[New Haven] 540.

leaf curl disease, cotton whitefly as vector, 811.

leaf curl disease in Northern India, 817.

leaf, studies, Conn.[New Haven] 469.

leaves, composition according to position on stalk, Conn.[New Haven] 510.

leaves, protein constituents, 223.

leaves, water-soaking injury to, relation to stomata, 624, Ky. 526.

legislation, Turkish, U.S.D.A. 585.

mosaic, Ga.Coastal Plain 378.

Tobacco—Continued.

- mosaic, reductions in yield and quality due to, Mass. 526.
- mosaic-resistant, Ky. 526.
- mosaic virus—
 - and host, temperature relations, 228.
 - disintegration in urea solutions, 228.
 - infectivity, effect of fine-curing, 59.
 - inhibition by insect juices, 52.
 - irradiated with X-rays of different wave lengths, behavior, 47.
 - movement in tomato plants, 664.
 - preparations, distintegration with sodium dodecyl sulfate, 229.
 - protein, Mo. 59.
 - protein, amino acids of, 581.
 - protein, molecular weight, 386.
 - protein, physical chemistry, 530.
 - protein, viscosimetric studies, 662.
- mosaic, wild hosts in Brazil, 58.
- moth, film spraying method for protection of stored goods from, 814.
- moth larvae, bacterial flora in gut, 811.
- moth, life history and control, 397.
- moth, tropical, biology and economic importance, 77.
- Perique, blackfire of, U.S.D.A. 655.
- physiology and nutrition, 784.
- plantbed disease, new, Ky. 526.
- plantbed fertilization, Fla. 200.
- plants grown on ammonia and nitrate nitrogen, organic acid metabolism, 181.
- prices and quality, seasonal fluctuations in, Ky. 585.
- response to liming, Ky. 501.
- root knot nematode, control, Ga.Coastal Plain 378.
- roots, distribution and development, 180.
- seed cleaner, construction, Mass. 579.
- seed, germination after 6 yr. in different types of storage, Fla. 200.
- seedbed disease survey, U.S.D.A. 655.
- seedbeds, bordeaux treatment, Ky. 526.
- sore shin, Ga.Coastal Plain 378.
- sun-grown, insect losses sustained in, Conn.[New Haven] 540.
- sun scald or sun burn, U.S.D.A. 525.
- thrips, Conn.[New Haven] 540.
- thrips on shade tobacco, Conn.[New Haven] 540.
- tissues, accumulation of nicotine in, 181.
- topping, suckering, and curing experiments, Ky. 501.
- variety tests, P.R.Col. 502.
- wildfire, U.S.D.A. 378.
- wildfire, epidemiology, 182.
- wildfire, transmission and control, Pa. 50.
- wireworms, Ky. 540.
- worm, notes, Conn.[New Haven] 540.
- yellow ring spot, symptoms and longevity of virus in seed, 386.
- yield and quality, factors affecting, Mass. 501.

Tomasia guppyi on sugarcane in Trinidad, 679.

Tomato—

- bacterial canker, Calif. 220.

Tomato—Continued.

- bacterial canker and fertilizer injury, U.S.D.A. 795.
- bacterial stalk rot, recognizing and treating, 663.
- blight, early, seed transmission, Ind. 655.
- bushy stunt virus, crystalline preparations, 230.
- disease resistant varieties, development, Wis. 527.
- disease situation in Utah, U.S.D.A. 525.
- diseases, control, Fla. 222, R.I. 795.
- diseases, foliage and virus, effect of sprays, Tex. 51.
- diseases on New York market, U.S.D.A. 48.
- early blight, behavior, Wis. 527.
- early blight, control, Del. 221.
- foot rot, Del. 221.
- fruits, effect of gases on, 526.
- fruitworm, control, 807, 814.
- fruitworm, notes, Ky. 540, S.C. 68, Tex. 67, Wash. 239.
- Fusarium* wilt, immunity to, 636.
- Fusarium* wilt resistant strain, John Baer, production, Mich. 230.
- Fusarium* wilt, studies, Tex. 51.
- growers, suggestions to, N.J. 515.
- juice, home-canned, vitamin C in, effect of methods of preparation, Wis. 141.
- leaf miner, control, 680.
- leaf mold in greenhouses, control, Mass. 798.
- leaves, protein constituents, 223.
- Macrosporium* disease, Ga.Coastal Plain 378.
- nailhead leaf spot, Fla. 222.
- nailhead spot, cause, Fla. 230.
- pathogens, soil-borne, control, Tex. 51.
- pinworm, Pa. 68.
- plant, effect of varying amounts of potassium on metabolism, 185.
- plants, composition, effect of potassium and nitrogen, N.H. 646.
- plants, effect of hardening on yield, R.I. 787.
- plants, fumigation, Fla. 238.
- plants, movement of tobacco mosaic virus in, 664.
- plants, Rutgers, sources and planting methods, 646.
- plants, southern- and home-grown, comparison, N.Y.State 211.
- pomace, dried, nutritive value, 256.
- psyllid, breeding areas, 237.
- ring spot, notes, Hawaii 655.
- root knot, Hawaii 655.
- roots, adventitious, growth and absorption of nutrients in air dry soil, 182.
- roots, excised—
 - experiments with growth substances, 349.
 - glycine in nutrition of, 182.
 - vitamin B₅ as growth substance for, 349.

Tomato—Continued.

- seed treatment, Ind. 655.
- seedlings, damping-off control, 59.
- seedlings, wind injury, Tex. 51.
- Septoria* and *Macrosporium* leaf spots, varietal susceptibility, 654.
- spotted wilt, U.S.D.A. 795.
- spotted wilt, Australian, in greenhouse grown crop, U.S.D.A. 220.
- spotted wilt virus, preservative effect of reducing systems, 280.
- tipblight disease, Oreg. 59.
- tipblight virus, properties, 60.
- virus-induced Australian spotted wilt, recognizing and treating, 668.
- wilt, control, Fla. 221.
- wilt resistant variety, 47.
- worm, notes. Conn.[New Haven] 540
- worm on tobacco, insecticide tests for control, S.C. 69.

Tomatoes—

- and tomato products, vitamin C in, Mass. 882.
- breeding, Conn.[New Haven] 512, Mass 512, N.Y.State 211, Pa. 40.
- breeding and pruning, Tex. 41.
- breeding for disease resistance, Del. 221.
- broomrape on, 798.
- canned, effect of adding calcium chloride, N.Y.State 759.
- canned, quality, Ind. 645.
- canning, root knot nematode important pest of, Ind. 886.
- costs, expenses, and returns from, Miss. 854.
- culture experiments, Fla. 210, Ga.Coastal Plain 374, Ind. 645.
- damping-off, seed and soil treatments for, 654.
- effect of copper sprays, Conn.[New Haven] 526.
- fertilizer experiments, Ga.Coastal Plain 374, Ind. 645, La. 645.
- fertilizer requirements, Wis. 512.
- food supply in, relation to fruit size, 790.
- for early market, higher yields from closer spacing, Miss. 787.
- growing, use of cloth houses, for, Okla. 40.
- growth and yield, effect of bordeaux spray, 798.
- growth and yield, relation to soil reaction, Fla. 210.
- household storage, 598.
- improvement with new hybrids, Fla. 210.
- inheritance of fruit size and shape, Iowa 40.
- modification of flower structure by environment, 48.
- new varieties, development, Calif. 209
- one and a half tons from fertilizer costing 48 cents, N.Y.State 213.
- production, problems in, Ill. 212.
- puffiness in, control, Fla. 210.
- puffing in, cause and nature, Tex. 41.
- root knot nematodes on, 654.
- roots, excised, growth in synthetic solutions, 188.

Tomatoes—Continued.

- seed, production, Ind. 645.
- shape indexes, Mass. 512.
- spray injury, R.I. 795.
- spraying experiments, Wis. 527.
- sprays for, Mass. 528.
- staking, R.I. 787.
- sweet, firm-fleshed, production with a minimum of seeds, S.Dak. 210.
- trace element deficiency, 798.
- transplanting, Wis. 512.
- trellised, culture, Mass. 512.
- unfruitfulness caused by male sterility, 496.
- varieties, N.Mex. 787.
- varieties and fertilization, S.C. 41.
- varieties, classification according to physiological response, 646.
- varieties for greenhouse culture, Okla. 40.
- variety and strain tests, Pa. 40.
- variety tests, Ga.Coastal Plain 374, La. 645, Pa. 374, R.I. 788, Wis. 512.
- vitamin C in, Fla. 301, Me. 141.
- vitamin C in, effect of season, Wis. 141.
- yield tests, Nebr. 645.
- Tornadic inception, temperature and vapor pressure as factors in, 169.
- Tortrix postvittana*—
 - life history and control, 396
 - new braconid parasite reared from, 824.
- Torula monosa*, heat resistance studies, 764.
- Towhee, red-eyed, new spirurid nematode from, 805.
- Towhees, descriptive account, 286.
- Tosoplasma hominis* from case of encephalomyelitis of an infant, 419.
- Tractor tests, official, N.Dak. 888.
- Tractors—
 - field machinery hitches for, S.Dak. 287.
 - rubber tires v. steel wheels for, Ind. 720.
 - trucks, and automobiles, 484.
- Trade—
 - agreement, German-Irish, extended, U.S.D.A. 292.
 - agreement, reciprocal, program, relation to southern economy, 290.
 - agreements, British Empire, relation to trade in farm products between Canada and United States, 481.
 - barriers—
 - internal, for farm products, U.S.D.A. 295.
 - resulting from State regulations, Iowa 292.
 - State, selected references, U.S.D.A. 588.
 - of southeastern Europe increasingly dominated by Germany, U.S.D.A. 585.
- Tradescantia*, microsporogenesis in, effect of dehydration, 628.
- Transpiration—
 - and fungus diseases, 656.
 - effect of bordeaux mixture and its various elements, 350.
 - of trees and forests, 376.
 - rate of tomato plants, effect of nutrient nitrogen level, 181.

Transpiration—Continued.

stomatal, relative humidity gradient, 624.

Tranzschelia pruni-spinosae on native California *Prunus* spp., 534.

Tree—

banding material, impregnated, studies, 69.

banding material, reel for carrying rolls, U.S.D.A. 241.

classification, Keen's, for use in growth studies and timber marking, 520.

diseases, 526, Mass. 527.

diseases, forest, Wis. 527.

diseases, forest, relation to stand improvement, U.S.D.A. 389.

diseases, important, of Mid-West, 238.

growth in Great Britain, role of climate and frost injury, 616.

growth, increment core handling, field book for, 521.

heights, measuring, extension rod for, 520.

insects, forest, P.R.Col. 541.

repairs, rubber blocks and wax for, 802.

ring analysis, value in engineering, 12.

ring work in Alaska, 12.

root knot in nurseries, heat treatments for, Okla. 50.

seedlings, propagation, Ind. 653.

temperatures and thermostasy, 180.

workers, requirements for, Conn.[New Haven] 157.

Trees—

behavior on soil profiles in Finger Lakes area, [N.Y.]Cornell 43.

best suited to semiarid conditions of western Kansas, 486.

broadleaved timber, production of forest planting stock, [N.Y.]Cornell 45.

calcium requirements, [N.Y.]Cornell 45.

coniferous, see Conifers.

destruction during New England hurricane, factors affecting, 616.

dormant season spraying of, N.J. 542.

forest—

breeding technic, 46.

composition and growth, effect of mineral fertilizers, [N.Y.]Cornell 45.

desirable species, 521.

effect on subordinate vegetation in forest, [N.Y.]Cornell 45.

tests, Wyo. 521.

growing grass under, 505.

hardwood—

avenues of entrance for canker-forming Nectrias, 63.

brush disposal in Hudson highlands, 378.

propagation, Pa. 45.

underplanting with pine, Ala. 46.

unusual growth and thinning operations, 521.

heartwood, formation and characteristics, 180.

marking method, 376.

Trees—Continued.

nursery, diseases of, 536.

rainfall conduction by trunks in tropical rain forest, 180.

root system of sprouting stump and undisturbed tree, 377.

shade and ornamental, diseases of, U.S.D.A. 48.

shade, insects affecting, 672.

shade, insects of Mid-West, 542.

sulfur in, relation to sulfur dioxide in atmosphere, 769.

transplanted, root development, effect of synthetic growth substances, 188.

treatments by injections, U.S.D.A. 242.

windbreak, Nebr. 376.

winter spraying, 815.

Trematode—

from herons, 105.

new, from rumen of cattle and buffaloes, 836.

Tribolium—

confusum, see Flour beetle, confused.

destructor, pest of stored products in England, 821.

Tribolium genus, physiological aspects, 274.

Trichinella—

larvae fed to immune rats, rapid loss of, 106.

spiralis—

functional buccal stylet in, description and mode of feeding, 711.

infestation, epidemiology and control, 419.

larvae, effect of heat on, 716.

Trichinosis in Alabama, 104.

Trichogramma—

cranescens, finding of hosts by, 241.

lutea, egg parasite of bollworm, 76.

minutum, control, P.R.Col. 541.

sembliidis, notes, 824.

sp., bionomics and mass breeding, 811.

spp., trend in natural parasitism of sugarcane borer by, 812.

Trichomonad flagellates in facial lesions of pigs, 111.

Trichomonas—

columbae and *Salmonella typhimurium*, isolation from diseased pigeons, 236.

gallinae in mouth, crop, and liver of pigeon, 114.

sp. from upper digestive tract of chickens, 718.

Trichomoniasis—

bovine, Calif. 273.

in cattle, control, 842.

venereal, experimental bovine, cases, 103.

Trichopoda sp., notes, 391.

Trichoptera, new genera and subgenera erected, 74.

Trichostrongylids from abomasum of reindeer, 836.

Trichostrongylosis—

in foals, treatment, 717.

in sheep and goats, 575, 836.

in sheep, course of, 844.

- Trichostrongylosis**—Continued.
in sheep, tobacco licks for prevention, effect, 843.
- Trichostrongylus axei**—
bionomics and seasonal incidence on irrigated pastures, 843.
notes, Calif. 273.
- Trigonella**—
foenum-graecum, susceptibility to root knot nematode, Tex. 52.
spp., as soil building crops, development and testing, Calif. 199.
- Trimethylamine oxide**, diffusion from udder, 101.
- Triolith**, toxicity, leaching, and fire-retarding effectiveness, U.S.D.A. 117.
- Triticum**, *Euchlaena*, and corn, genetic and cytological relations, Tex. 37.
- Triticinae**, amphidiploids in, induced by colchicine, 191.
- Triticum** spp., mutants and linkage studies in, Mo. 636.
- Tritoxa flexa**, notes, Iowa 65.
- Tritrichomonas foetus**, cultivation in developing chicken embryos, 419.
- Trout**—
body proportions, [N.Y.]Cornell 66.
food in a Centre County stream, Pa. 68.
nutritional requirements, [N.Y.]Cornell 66.
streams, conditions determining productivity and suggestions for stream and lake management, 805.
- Truck crop**—
diseases on Long Island, U.S.D.A. 525.
insects, Tex. 66.
- Truck crops**—
effect of atomized oil sprays, Wis. 541.
fertilization, Pa. 40.
precooling for eastern shipment, Calif. 257.
production, Hawaii 644.
residual effects from different levels of fertilizer, R.I. 775.
selection and breeding, Wash. 211.
- Trucks**—
hill climbing ability, determination, U.S.D.A. 118.
use and cost of operation on farms, Ind. 721.
- Tryblidella** spp., validity and morphology, 183.
- Trypanidae**, Australian and oriental, 550.
- Trypanosoma**—
cruzi, infection in rats, age resistance, 278.
equiperdum—
effect of splenectomy and blockade on protective titer of antiserum, 278.
infection in rats, role of potassium in death from, 278.
infections in rats of different age groups, activity of Germanin on, 278.
eransi, transmission experiments, 887.
- Trypanosoma**—Continued.
spp., age resistance of rats against, 105.
- Trypetidae**, South African, biological and systematic notes and records, 79.
- Tryptophane**, growth promoting substance from, 180.
- Tubercle bacilli**—
avian, in dressed poultry, 286.
avian, role in sensitization of cattle to tuberculin, 842.
human and bovine, comparative study, 103.
human, causing infection in cows in India, 836.
immunity experiments on guinea pigs, 712.
susceptibility of cats to, 111.
types, susceptibility of voles to, 572, 711.
- Tuberculin**—
proteins, human, bovine, and avian, distinguishable by precipitin test, 419.
purified protein derivative (P.P.D.) from human strain for testing cattle, 421.
synthetic medium, potency for double intradermal test in cattle, 713.
tests, Wis. 104.
- Tuberculosis**—
among animals other than domestic cattle in India, 836.
avian, biologic characteristics, 286.
bovine, Calif. 273.
control, 279, 570.
eradication in Canada, progress, 279.
historical chronology, 419.
immunity experiments in calves by use of B. C. G. in oily excipient, 713.
inherited natural resistance to, nature of, 29.
of goats in Uganda, 110.
of sheep due to bovine type, 844.
of sheep in Uganda, 110.
role of inherited natural resistance to, 29.
spontaneously acquired in rhesus monkeys, 712.
vitamin C in, 152.
- Tulip blight**, control, 536.
- Tulips**, dark red, roguing for mosaic disease, 233.
- Tumor formation in plants**, effect of colchicine, 53.
- Tuna fish**, canned, spoilage in, evaluation, 8.
- Tung-oil**—
experiments at Everglades Substation, Fla. 210.
seedlings, effect of root knot nematode, 501.
- Tung trees**—
abnormalities, La. 656.
adaptability tests, Ga.Coastal Plain 374.
dying, associated with *Dothiorella* sp., La. 656.
fertilizer and adaptation studies, Tex. 41.
growing, La. 645.

Tung trees—Continued.

Phytophthora cinnamomi root rot of, La. 656.

propagation and culture, Fla. 210.
response to good treatment, Miss. 787.
triangular planting for, Miss. 787.

Turf—

and turf grasses, diseases, R.I. 795.
snow mold in Alberta, 796.

Turkey—

diseases, Oreg. 103.

eggs, hatchability, factors affecting, Ky. 553, S.Dak. 255.

flesh, flavor, effect of fish oils and fish meals, Calif. 254.

flocks, genetic differences in, Nebr. 689.
grading program, State-wide, Okla. 86.
meat, fishy flavor and odor in, Pa. 86.
meat, fishy flavor, cause, Va. 830.
rations, peanut products for, Fla. 255.
rations, types, Calif. 254.

research substation of New Jersey Station, 606.

Turkeys—

artificial insemination of, U.S.D.A. 778.
blood alterations in typhlohepatitis, 104.
breeder, vitamin G requirements, Colo. 95.

breeding for specific body size, Ind. 688.
breeding, value of all-night lighting for, Okla. 86.

crooked breastbones in, elimination, Wyo. 554.

egg production in first laying year, factors affecting, 561.

finishing rations, Wash. 561.

growth and feed utilization, effect of protein intake, 264.

host of *Prosthogonimus macrorchis*, 425.
inheritance of body size and shape in, Okla. 28.

iron-deficient, papillomatous growths on feet and legs, 114.

Leucocytozoon smithi in blood of, 848.
manganese requirements of, Ky. 553.

market quality, relation to body conformation, Okla. 85.

millet feeding for, N.Dak. 561.

nutritive requirements, Wash. 255.

optimum crude fiber level for, Okla. 85.
optimum protein levels for, Okla. 85.

production, Okla. 95.
range requirements, Okla. 86.

susceptibility to chicken coccidia, Wis. 104.

tarsometatarsal length, effect of heredity, 104.

use of artificial lights for, 699.

vitamin D requirements, 698.

Turnip—

aphid, Tex. 66.

green, available iron in, 596.

Turnips, seed treatment for, Tex. 51.

Turpod fly, notes, 810.

Turtle parasites, hemoglobin in, 105.

Tyloderma fragariae, see Strawberry crown borer.*Typhlocyba*—

australia in South Australia, 75.

pomaria, see Apple leafhopper, white.

Typhlohepatitis of turkeys, blood alterations in, 104, 578.

Typhoid, avian, see Fowl typhoid.

Typhula spp., life history and taxonomic studies, [N.Y.] Cornell 49.

Typhus—

fever, endemic, susceptibility of animals to virus, 279.

group rickettsiae, developing chick embryo as medium for growing, 277.

Ultraviolet radiation, effect on plants, Pa. 22.

Uncinariolosis of silver foxes, anthelmintic efficacy of tetrachlorethylene v. sprehn-cap-sules, 834.

U. S. Department of Agriculture—

abbreviations used in, for titles for publications, 750.

appropriation act. 1940, 753.

Bureau of Biological Survey, see Bureau of Biological Survey.

Office of Experiment Stations, see Office of Experiment Stations.

Soil Conservation Service, see Soil Conservation Service.

University patents, economic aspects, 584.

Urea as protein substitute in diet of young cattle, 97.

Urea nitrogen, utilization by swine, Hawaii 688.

Urease concentrate, relatively stable, preparation from blowfly, 838.

Uredinales, new species, 223.

Uric acid of blood and urine, effect of dried yeast, Pa. 141.

Urinary calculi—

analysis and cause in yearling bull, 407.
in rabbit, 836.

Urine—

human, vitamin C in, determination, 614.

pregnancy, injection and coitus, comparison as stimuli for ovulation in rabbit, 31.

pregnancy, of cattle, effect on lactation in virgin rabbits, 31.

Urnisa sp., notes, 244.

Urocheta luteovarioria, notes, 398.

Uromyces—

graminis, aecidial stage, new hosts for, 53.

n.spp., description, 243.

phaseoli typica, notes, Hawaii 655.

Uropyxis n.sp., description, 223.

Ustilaginales of Utah, 382.

Ustilago—

hardii and *U. nigra*, susceptibility of forage grasses to, 352.

nigra and *U. hardii*, susceptibility of forage grasses to, 352.

seae, growth types, genetic and environmental factors, 382.

Utah College, notes, 160.

Utah Station, notes, 160.

Utah Station publications, annual summary, 751.

Uterus, immature rat, for assay of estrogenic substances, 198.

Valanga nigricornis on corn in Java, 393.

Valine, dietary indispensability, 450.

Vadalia, maintenance of supply, P.R.Col. 541.

Vegetable—

diseases—

control, new equipment and new materials for, 663.

greenhouse, control, Mass. 527.

greenhouse, recognizing and treating, 663.

in New York, U.S.D.A. 655.

notes, 788.

on New York market during winter, U.S.D.A. 525.

seed- and soil-borne, Fla. 221.

growers of New Jersey, economic situation facing, N.J. 586.

insects, control, U.S.D.A. 806.

insects in Jordan Valley and Upper Galilee, 809.

juices, Calif. 165.

leaf blights, Fla. 221.

pests and parasites, 672.

pests, control schedule, Conn.[New Haven] 157.

products, studies, Wash. 165.

seed treatment, U.S.D.A. 229.

seeds, production, N.Mex. 787.

weevil, Ala. 65.

Vegetables—

adapted to Florida, selection and development, Fla. 210.

breeding and selection, Mass. 512.

containers for, U.S.D.A. 513.

cooking, chemical changes in, Mass. 591.

cooperative marketing, 295.

culture and fertilization, Tex. 41.

fertilization, Fla. 210.

fertilizer placement for, 179.

fertilizer requirements, Fla. 210. [N.Y.] Cornell 42, R.I. 787, Wash. 211.

for canning and freezing, development, Tex. 41.

fresh, rate of deterioration, effect of temperature, 788.

frozen, criteria for judging quality, 592.

frozen-pack, bacteria surviving in, 303.

greenhouse-grown, minor element problem in, 631.

growing and marketing, treatise, 42.

grown on muck soil, soil management for, [N.Y.] Cornell 42.

growth, yield, and quality, effect of green manure crops, Fla. 210.

handling and storage, [N.Y.] Cornell 42.

high in mineral and vitamin content, selection of genetic strains, Me. 140.

home preparation for freezer-locker, Tenn. 303.

household storage, 593.

leafy, hemoglobin-regenerating properties of, Miss. 864.

marketing, Ind. 645.

marketing in Detroit, Mich. 295.

Vegetables—Continued.

marketing on farmers' markets in New York Metropolitan District, [N.Y.] Cornell 129.

marketing, quality as factor, Tex. 122.

minerals in, Mass. 469.

native, market outlets and local uses for, N.Mex. 860.

plant pigments in, Calif. 165.

precooling and storage on farm, [N.Y.] Cornell 42.

precooling prior to long-distance shipments, Calif. 210.

preparation for frozen storage, Miss. 865.

preservation by freezing in Pacific Northwest, U.S.D.A. 738.

preservation in cold storage lockers, N.Dak. 142.

soil deficiencies for and use of borax, [N.Y.] Cornell 42.

soil management for, Conn.[New Haven] 476.

soil preparation for, Mass. 512.

soil reaction for, [N.Y.] Cornell 42.

strains and varieties, R.I. 787.

types, Tex. 41.

varieties, Iowa 40, Wash. 211.

varieties for freezing preservation, West. Wash. 374.

varieties for the garden, N.Dak. 211.

varieties, irrigation, and fertilizers for, Okla. 40.

varieties, propagation, Alaska 374.

variety tests, Fla. 210, Ga.Coastal Plain 374, Ky. 512, Me. 40, Pa. 374, R.I. 788, Wis. 512.

vitamin B₁ and B₂ (G) content, 181.

vitamin C in, Fla. 300.

vitamin C losses during cooking, 314.

yield, effect of sources of nitrogen, Ala. 39.

Vegetation—see also Flora and Plants.

and asymmetry in forest trees of Columbia River gorge, 185.

effect of sulfur dioxide on, 769.

estimating density of, 520.

relation to physicochemical properties in soils, Mass. 477.

Velvetbean caterpillar, tests with basic copper arsenate, 244.

Velvetbeans—

culture experiments, Fla. 200, Ga.Coastal Plain 363.

in the pod and ground for steer fattening rations, Fla. 254.

nutritive values, P.R.Col. 255.

variety tests, Ga.Coastal Plain 363, Tex. 36.

Venturia inaequalis perithecia, active in New York, U.S.D.A. 795.

Vermont Station, notes, 607.

Vernalization—see also specific crops.

and early development, factors causing, 180.

Verticillium—

dahliae disease of chrysanthemum, symptoms, 233.

Verticillium—Continued.

- wilt of cotton, control, 654.
- wilt of peach trees, U.S.D.A. 795.
- wilt of pepper, 56.

Vetch—

- Calcarata, as soil-building crop, Calif. 200.
- hairy, fertilizer and liming studies, La. 639.
- hairy, for soil improvement, Tex. 37.
- hairy, inoculation, La. 639.
- hairy, nodulation, growth, and nitrogen in, effect of fertilizers 371.
- hairy, rate of seeding tests, West.Wash. 363.
- variety tests, Tex. 37.

Veterinarians, regional of Colombia, 464.**Veterinary, see Animal diseases.****Vetiver, growing, La. 645.****Vincent's disease in dogs, treatment with nicotinic acid, 718.****Vines, improvement by grafting and budding. Miss. 787.****Virginia Station, notes, 464, 892.****Virus**—

- in sauerkraut, 882.

- in sauerkraut, home-made, Wis. 141.

- in tomatoes, Fla. 301, Me. 141.

- in tomatoes and tomato juice, Wis. 141.

- in tomatoes and tomato products, Mass. 882.

- in tonsils and blood of children, relation to streptococci in tonsils, 151.

- in Virginia apples, 883.

- in vitro, 180.

- in Wisconsin-grown apples, Wis. 141.

- losses from carrots during cooking, 146.

- losses from frosted peas during freezing, defrosting, and cooking, 146.

- metabolism, effect of hyperthyroidism, 599.

- status of college women, 148.

- status of diabetic patients, 151.

Vitamin D—

- A. O. A. C. chick assay for, limit of accuracy, 829.

- assay with chicks, 829.

- bioassay of milk, standard methods, 456.
- chemistry, 310.

deficiency—

- clinical tests for, status, 456.

Vitamin D—Continued.

deficiency—continued.

effect on dairy cows, S.Dak. 265.

enzymic efficiency in, Ark. 457.

in cows, 703.

relation to dental caries, 599.

from several sources, relative efficiency, 88.

in diet, palatable methods of supply, 153.

physiology and pathology, 310.

potency of milk, effect of roughages, S.Dak. 265.

production in milk, irradiation process, 701.

protection against metaphyseal decalcification, radiographic demonstration, 818.

requirements of chicks, Tex. 87.

requirements of different breeds of chickens, Wis. 554.

requirements of pigs, 693.

requirements of young turkeys, 698.

shock therapy, 745.

stability in irradiated evaporated milk, 317.

stability in oily solution, 456.

storage in calves, Pa. 97.

yield from ergosterol, factors affecting, Wis. 141.

Vitamin D₂, response of rats to, 884.

Vitamin E—

and nutritional muscular dystrophy, 557.
decreased body reserves, effect on reproduction of goats, 402.

destruction by rancid fats, 746.

effect on reproduction in cows, Oreg. 96.
in wheat germ oil, relative requirements of male and female rats, Idaho 741.

low rats, degeneration of cross striated musculature in, 154.

relation to sterility in cattle, Iowa 95.

studies with male rats, 703.

Vitamin F, *see* Vitamin B₆.

Vitamin, factor W, possible complexity, Wis. 142.

Vitamin G—*see also* Riboflavin.

complex in potatoes, factors of, Idaho 741.

deficiency, enzymic efficiency in, Ark. 457.
in oil press-cake meals and related products, 557.

in vegetables, 181.

Vitamin K—

and anti-gizzard-erosion factor, Calif. 254.

concentrations, assay, 406.

effect on blood coagulation time in bile fistula or jaundiced rats, 746.

effect on prothrombin and clotting time in newly born infants, 600.

in calf blood, effect of atypical blindness-producing ration, 403.

in chicks, estimation, 257.

in treatment of jaundice, 456.

properties, distribution, and importance, 456.

requirements of rat, 746.

Vitamin M deficiency in monkeys, 459.

Vitamins—

and dental caries, 310.

and hormone research, results, 310.

and vitamin deficiencies, treatise, 145.

deficiency, *see* Avitaminosis and specific vitamins.

effect on germination of pollen and fungus spores, 766.

in foods, retention, restoration, and fortification of, 746.

in milk, factors affecting, [N.Y.]Cornell 96.

in nutrition of animals, 557.

in tomato pomace, 256.

interrelations, effect of avitaminosis, 874.

production in agriculture, 692.

requirement of different species as function of size, 144.

Volatile compounds, testing toxicity of, 656.

Voles, susceptibility to types of tubercle bacilli, 572, 711.

Voltage regulator, electronic, with supplementary circuit to supply low voltages, 325.

Vultures, American, and toxin of *Clostridium botulinum*, 114.

Walnut—

blight control, new copper spray for, 535.

caterpillar on pecans, control, Okla. 68.

husk fly, Calif. 238.

husk fly, varietal susceptibility of walnuts to, 79.

Walnuts—

bordeaux injury, 63.

boron injury to, Calif. 220.

nutcracking device for securing whole or half meats, Calif. 287.

Warble flies of Manchuria and Inner Mongolia, 78.

Warehouse system, nation-wide, proposed by Yugoslavia, U.S.D.A. 432.

Washington Station, notes, 464, 592.

Washington Station, report, 319.

Water—

absorption by dry organic matter, mathematical processes involved, 623.

conduction from shallow water tables, Calif. 581.

contaminated by phenolic wastes, 106.

control investigations at Everglades Substation, Fla. 287.

duty of, *see* Irrigation water.

electric heating, cost, Wash. 257.

facilities program, outline, U.S.D.A. 580.

flow and distribution in soil, Iowa 13.

flow in canals for irrigation or other uses, U.S.D.A. 580.

flow in main diversion floodway of Little River drainage district, U.S.D.A. 850.

fluorine content, Ky. 469.

intake, effect of soil type, slope, and surface conditions, Nebr. 618.

level, studies, Nebr. 617.

losses from soil, factors affecting, Tex. 14.

Water—Continued.

- of Texas, iodine content, Tex. 87.
- resources and geology of Snake River Plain in, Idaho 426.
- resources in Grand Prairie of Arkansas, 720.
- resources of Holbrook region of Arizona, 579.
- supply and precipitation in Sierra Nevada region, 333.
- supply of United States, 116, 579.
- supply of United States, Hudson Bay and upper Mississippi basins, 287.
- supply of United States in Ohio River Basin, 850.
- supply, rural, and sewerage, 427.
- surfaces, evaporation from, U.S.D.A. 333.
- table depths, effect on crop yields, Fla. 237.
- weight in soil or subsoil mass in which moisture increases with distance from plants, 174.

Waterfowl—

- breeding areas, plants in, distribution and ecology, Iowa 17.
- disastrous effects of oil pollution in San Francisco Bay region, 236.
- natural plantings for attracting to marsh and other water areas, U.S.D.A. 668.
- situation, U.S.D.A. 669.
- winter losses from starvation and exposure, 804.

Waterlilies, tropical, notes, 211.**Watermelon—**

- blossom-end rot, cause, 281.
- Pythium* root rot, 531.
- soft rot, 384.
- wilt and other diseases, control, Fla. 221.
- wilt-resistant varieties, 231.
- wilt-resistant variety, seedling structure, Iowa 49.

Watermelons—

- breeding and selection of better disease-resistant strains, Iowa 48.
- fertilizer experiments, Ga.Coastal Plain 374, La. 645.
- fruit shape and flesh color, inheritance, Iowa 48.
- induced parthenocarp of, 492, 513.
- varieties and fertilization, S.C. 41.
- variety tests, Ga.Coastal Plain 374, La. 645.

Watershed—

- and hydrologic studies on Blacklands experimental watershed, 720.
- Black Lands experimental, geological structure and ground water graphs, U.S.D.A. 851.

Watershield as duck food, U.S.D.A. 538.**Wax moth, braconid parasite of, 811.****Weasel, phenomenal infestation of ectoparasites, 672.****Weather—see also Meteorological observations and Meteorology.**
